THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME XVII.

FROM MAY 14 TO NOVEMBER 5, 1886.

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.

LONDON:

Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1886.

INDEX TO VOL. XVII.

51287

A

Adams, A. J. S , Earth Conduction, 108.
Aerial Conductors (*see* WIRES, OVERHEAD).
Africa, West, New Cables to, 155.
Africa, West, a Telegraph Station in, 234, 236.
Air Pump, Mercurial, by J. F. Bottomley, 392.
Alternating Currents, by Max Deri, 265.
American Fire Office Rules for Electric Lighting, 458.
American Tramway Company, Report of, 536.
Ampère's Law, by P. Duhem, 424.
Ampère's Rule, Graphic Representation of, 215.
Anderson, Sir J., Telegraphic Reform, 168.
Anglo-American Brush Corporation *v.* Crompton, 205.
Anglo-American Brush Corporation's Works, 354.
Arc Lamp for Lecture Illustration, Gray's, 223.
Atlantic Cable, Another Suggested, 198, 216.
Atlantic Cables, the Tariff War, 112.

B

Bailey, W., Curved Diffraction Gratings, 80.
Baltimore Tramway Company, Report of, 536.
Bannatyne *v.* Direct Spanish Company, 537.
Bassano Telephone Appeal, the, 152, 161.
Batteries, Primary :—
  Irregular Action of, 29.
  Lalande's, 281.
  Pollak's, 13.
  the Regent, 298.
  Seat of E.M.F. in, by Dr. W. Ostwald, 179.
  (*see* PEUKERT).
  Standard Cells, by A. Muirhead, 490.
  Upward's, 153, 385.
  with Aluminium Electrode, E.M F. of, by A. P. Laurie, 260.
Batteries, Secondary :—
  Kirchkof's, 111.
  Treatment of, by B. Drake and J. M. Gorham, 384.
Beaumont, W. W., Mechanism for Recording Variable Velocity, 364.
Bell, C.A., Sympathetic Vibration of Jets, 80.
Belling, the Cat (Leading Article), 321.
Berlin Physico Technical Institute, 257.
Bidwell, S., Lifting Power of Electro-magnets, 136.
Bidwell, S , Magnetic Torsion of Iron and Nickel Wires, 347.
Bidwell, S., Modified Wheatstone Rheostat, 79.
Bismuth, Variation in Resistance of in the Magnetic Field, by A. Leduc, 338.
Blackpool Electric Tramway, by M. H. Smith, 370.
Blyth, Prof. J., Miller's Magnetometer, 478.
Blyth, Prof. J., New Current Weigher, 456.
Bottomley, J. T., Mercurial Air Pump, 392.
Bottomley, J. T., New Form of Sine Galvanometer, 433.
Bottomley, J. T., Resistance of Metals at High Temperature, 394.
British Association (*see* SOCIETIES' MEETINGS).
Brush's Great Dynamo, by R. H. Thurston, 469.
Brussels, Lighting Exhibition at, 158.
Business Notices, 40, 59, 162, 226, 524.

C

Cable, Atlantic, Another Suggested, 198, 216.
Cables, Atlantic, the Tariff War, 112.
Cable Companies, Statistics of Capital, &c., 170.
Cable Convention, the (Leading Article), 10.
Cable Stories Retold, by F. C. Webb, 178.
Cables, the Neutralisation of, 168.
Cables, New, to West Africa, 155.
Cables to New Zealand, 534.
Callow *v.* Young, 541.
Cantor Lectures (*see* FORBES).
Carbons for Incandescent Lamps, by A. S. Hickley, 481.
Cardew, P., the Telephone in Military Telegraphy, 73.
Case, W. E., New Means of Converting Heat Energy into Electrical, 264.
Cavendish's Method as to the Law of Inverse Squares, Proof of, by Prof. Poynting, 343.
Chamberlain and Hookham's Dynamo, 429.
Chambers, J. M., Hall's Phenomenon, 69.
Chambers, J. M., Pyro-electric Crystals, Dielectric Action, and Kerr's Phenomenon, 193.
Chambers, J. M., Weberian Theory of Diamagnetism, 27.
Chemistry as a Science, by Prof. Crookes, 415, 436, 460.
City and Guilds Examinations, 300, 498, 516.
Co-efficient of Self-induction, by MM. Vaschy and de la Touanne, 328.
Colardeau, E., Induction Caused by Motion, 117.
Colladon, D., Thunderclouds, 156.

COMPANIES' MEETINGS :—
  Anglo-American Telegraph, 225, 241.
  Australasian Electric Light, 120, 161.
  Brazilian Submarine, 18, 524, 542.
  Consolidated Telephone, 82, 100.
  Cuba Submarine, 270, 287.
  Direct Spanish Telegraph, 417, 440, 482, 501.
  Direct United States, 206, 242.
  Eastern Telegraph, 186, 205, 224.
  Eastern Extension Telegraph, 502, 522.
  Edison and Swan, 244.
  Edison's Indian and Colonial, 162.
  French Atlantic Cable, 418.
  Globe Telegraph and Trust, 240.
  Great Northern Telegraph, 19.
  India Rubber, 225.
  London Platino-Brazilian, 59, 80.
  Manchester Edison, 373.
  Maxim-Weston, 441.
  National Telephone, 270, 288.
  Oriental Telephone, 40.
  Pilsen-Joel, 542.
  South of England Telephone, 270, 289.
  Submarine Cables Trust, 19.
  Submarine Telegraph, 246, 269.
  Telegraph Construction, 225.
  Telephone Company of Egypt, 58.
  United Telephone (London), 162, 184.
  United Telephone of the River Plate, 482.
  West African Telegraph, 186.
  West Coast of America, 59, 81.
  West India and Panama Telegraph, 40, 57.
  Western Union Telegraph, 542.

Conductivity of Double Salts, by E. Klein, 424.
Conductors for Incandescent Lighting, by H. W. Leonard, 217.
Congress on Telegraphic Reform, 168, 196.

CONTEMPORARY PROGRESS :—
  Duhem on Ampère's Law, 424.
  Klein on the Conductivity of Double Salts, 424.
  Kundt on the Double Refraction of Light in Metallic Films, 337.
  Kundt on the Electro-Magnetic Rotation of the Plane of Polarisation of Light in Iron, 530.
  Leduc on the Deflection of the Equipotential Lines and the Resistance of Bismuth, 338.
  Renard on the Electrolysis of Salts, 427.
  Sohncke on the Electro-magnetic Rotation of Ordinary Light, 339.

CONTEMPORARY PROGRESS *(continued)* :
  Thompson, S. P., on the Law of the Electro-magnet, 336.
  Tumlirz on Rock Crystal in a Magnetic Field, 337.

Copper, Deposition of, by R. H. Sankey, 74.
Copper and Silver, Electrolysis of, and its Application to Standardising Meters, by T. Gray, 404.

CORRESPONDENCE TO "THE ELECTRICIAN" :—
  Ampère's Rule, 235, 259, 279, 321, 341.
  Arc Lamp, Small, 389.
  Barrett, W. F., Earth Currents, 322.
  Batteries, Primary :—
    Lalande's, 298, 321.
    Maquay's, 259, 340, 367.
    Navigation by Means of, 409.
    the Regent, 259, 340, 367.
    Schanschieff's, 31.
  Batteries, Secondary, Construction of, 46.
  Cable Rates to New Zealand, 534.
  Caine, L. E., Negative Charge, 321, 391.
  Cardew, P., Military Telegraphy, 133.
  Cardew's Method of Testing Dynamos, 410, 431, 454.
  Carswell, T. P., Train Lighting, 341.
  Chambers, J. M., Ampère's Rule, 235, 279.
  Current Induction, 93, 113.
  Dynamo, New Type of, 133.
  Dynamo Tests, Cardew's Method, 410, 431, 454, 513.
  E., Keeping it Constant at a Distance, 71.
  Earth Currents, 322.
  Electric Bells, 46, 71, 93, 297.
  Electric Lighting :—
    for Bournemouth, 454.
    and Eyesight, 453.
    at the Hotel Schweizerhof, 297.
    in Italy, 410.
    a Practical Question, 471.
    in Spain, 367, 399.
    for Trains, 341.
  Electric Locomotive Company, 493.
  Electrical Machine, an Old, 198.
  Electricity *v.* Heat, 11.
  Evershed, S., Divided Mains, 71.
  Fitz Gerald, D. G., Lithanode, 409.
  Foot Warmers, the Heating of, 237.
  Frempt, H. C., Underground Insulation, 322.
  Galvanometer Coils, the Winding of, 390.
  Galvanometer Scales, 493.
  Goolden and Trotter's Large Dynamo, 31.
  Gordon's Divided Main Apparatus, 71.
  Hemecans, G. H., Galvanometer Coils, 390.
  Hughes's, D. E., Magnetic Researches, 197.
  Incandescent Lamp Dispute, the, 198, 235, 279, 298, 343.
  Incandescent Lamp, Figures Relating to Current, &c., 410.
  Incandescent Lamp Filaments, Effect of Variation in, 277.
  Incandescent Lamps, Renewal of, a Practical Question, 471.
  Induction, Current, 93, 113.
  Induction on Underground Telephone Lines, 322.
  Information Wanted About Electrical Machine, 198, 237.
  Insulation, Underground, 322.
  Iron Watches, 175.
  Johnstone, J., Sabine *v.* White, 11.
  Kapp, G., New Type of Dynamo, 133.
  Lalande's Battery, 298, 321.
  Launch, Electric, "The Volta," 409.
  Lieb, J. A., jun., Electric Light in Italy, 410.
  Lithanode, 390, 409.

CORRESPONDENCE *(continued)*:
Mackay-Bennett Cables, the, 281.
Magnetic Researches, 197.
Maquay's Battery, 259, 367.
Menges, C. L. R. E., Dynamo Tests, 431, 454.
Military Telegraphy, 114, 133.
Mines, Shot Firing in, 235.
Moseley, W., Lithanode, 390.
Moseley, W., the Telephone System, 390.
Multiple Switch-board, 410.
Nairne's Electrical Machine, 198, 237.
Navigation by Primary Battery Power, 409.
Negative Charge, 259, 279, 321, 341, 391.
Nervous Force and Electricity, 133, 175, 198, 217.
New Zealand, Cable Rates to, 535.
Ozone and Other Gas, 11.
Paddington Installation, 71.
Penruddocke, C., the Regent Battery, 367.
Phonoplex, Edison's, and the Telephone, 46.
Pope, G. C., Electric Light and Eyesight, 453.
Practical Question, a, 471.
Regent Battery Prospectus, 340, 367.
Rennie, J., Galvanometer Scales, 493.
Ross, O. C. D., Navigation by Primary Battery Power, 409.
Sabine *v.* White, 11.
Schanschieff's Battery, 31.
Schweizerhof Hotel Installation, 297.
Selby, J. A., Electric Light in Spain, 367.
Sellon, J. S., Heating Foot Warmers, 237.
Shippey, A., Incandescent Lamp Patents, 298.
Soldering Wires with Spirits, 46, 71.
Tadpoles, Polarity of, 31.
Telephone Cables, Felten and Guilleaume's Anti-induction, 471.
Telephone and the Post Office, 46.
Telephone, Query as to Purchasing, 47.
Telephone and the Sounder, 46
Telephone in Small Towns, 431.
Telephone System, the, 367, 390.
Thompson, N. G., Effect of Varying Incandescent Lamp Filaments, 277.
Thompson, N. G., the Regent Battery, 367.
Thomson-Houston System, the, 153.
Train Lighting, 341.
Tramcar, Electric, 536.
Truenfeld, R. von F., Military Telegraphy, 114.
Trotter, A. P., Cardew's Dynamo Tests, 410.
"Volta," the, Electric Launch, 409.
Walker, S. F., Maquay's Battery, 259.
Walker, S. F., Shot Firing in Mines. 235.
Ward, R., Electric Tramcars, 536.
Ward, R., the Regent Battery Prospectus, 340.
Willey, A., Nervous Force and Electricity, 133, 175, 217.
Williams, E. A., Negative Charge, 259. 341.
Williams, E. A., Current Induction, 93, 113.
Williams, E. A., Nervous Force and Electricity, 198.

CORRESPONDENCE, SELECTED :—
Judges and Patents, 166, 219, 309.
Correspondents, Answers to, 452, 472.
Creil Experiments, Report on, 318.

CRICKET :—
Carcavellos *v.* Victoria, Lisbon, 206.
Eastern *v.* Anglo-American, 142.
Eastern *v.* Submarine, 59, 61.
Lancashire and Cheshire Telephone Company, Manchester, *v.* Liverpool Staff, 102, 418.
Willans and Robinson *v.* Woodhouse and Rawson, 226.

Crompton Apparatus used at Tilbury, 306.
Crookes, Prof., Address to Mechanical Science Section of British Association, 415, 436, 460.
Cross, C. R, Platinum Light Standard, 514.
Current, Divided, Experiment on, by Lord Rayleigh, 412.
Current and Potential Meters of the Nature of Aerometers, 97.
Current, Self-induction of, by D. E. Hughes, 71, 95, 118.
Current Weigher, Blyth's, 456.
Currents, High Tension, for Lighting, by E. Hospitalier, 131.
Currents, Alternating, by Max Deri, 265.
Cuttriss's Siphon Vibrator for Cables, 222.
Crystals, Pyroelectric, by J. M. Chambers, 193.

D

Dawson, Sir W., Address to British Association, 348, 368, 395, 416, 438.
Deprez's Experiments between Paris and Creil, 318.
Deri, Max, Alternating Currents, 265.
Detonators, Electric, Apparatus for Testing, 214.
Detonators, Electric, for Mines, 91, 213.
Diamagnetism, Weberian Theory of, by J. M. Chambers, 27.
Dielectric Action, by J. M. Chambers, 193.
Diffraction Gratings, Curved, by W. Baily, 80.
Drake and Gorham on Secondary Batteries, 384.
Duhem, P., Ampère's Law, 424.
Dust and Smoke Depositor, 510.

DYNAMOS :—
Brush's Great, by R. H. Thurston, 469.
Chamberlain and Hookham's, 429.
Dead Turns of, by S. P. Thompson, 175.
Gordon's Illustrated (*see* SUPPLEMENT of May 28).
The Jenney Company's, 34.
Law of, by S. P. Thompson, 336, 494.
(*see* PEUKERT).
Thomson's, 468.
Thury's, 493.
Transmission of Power to, by J. A. Pentz, 459.

E

Earth Conduction, by A. J. S. Adams, 108.
Earth Current Storm, Mr. Holst's Observations, 260.
Earth's Magnetism, Kohlrausch's Variometer, 14.
Earth's Magnetism, Methods of Measuring, by F. and W. Kohlrausch, 253.
Earthquake in Greece, Report on, 406.
Edison and Swan *v.* Holland and the Jablochkoff Company, 287.
Edison and Swan *v.* Woodhouse and Rawson, 18, 37, 48, 50.
Edison's System of Telegraphing with Trains, 56.
Edgerton's Motor, 259.
Educational Apparatus, 510.
Electric Bells, 6, 26, 90, 150.
Electric Lamp, Portable, by W. H. Preece, 359.

ELECTRIC LIGHTING :—
American Fire Office Rules for, 458.
For Chelsea, 132.
at Edinburgh Exhibition, 17.
and Exhibitions (Leading Article). 512.
and Eyesight (Leading Article), 430.
and High-tension Currents, by E. Hospitalier, 131.
Incandescent System, by T. C. Martin, 434, 459.
in Madrid, 16.
National Association of the U.S.A., 413, 434, 459, 481.
at St. Etienne, 387.
in the Suez Canal, 34.
at Tilbury Docks, 301.
Tower, New, 34.
in Wentworth Castle, 448, 452.
Wind Power for, 323.

Electric Lighting Act Amendment Bills, 17, 92, 99, 280.
Electrical Residue, Demonstration of, 195.
Electrical Standards, Report of British Association Committee on, 433.
Electrical Theories, by J. J. Thomson, 138, 154, 180, 201, 261, 324.
Electrical Theory of the Universe (Leading Article), 320.
Electricity, Cantor Lectures on, by Prof. G. Forbes, 36, 77, 97, 159, 203.
Electro-chemical Equivalent of Silver, by F. and W. Kohlrausch, 253.
Electrolysis, by O. J. Lodge, 307, 325, 351, 396, 499, 516, 532.
Electrolysis of Salts, by A. Renard, 427.
Electrolysis of Silver and Copper and its Application to the Standardising of Measuring Instruments, by T. Gray, 404.
Electrolytes and Transfer Resistance, by Dr. G. Gore, 57.
Electrolytic Cells, by Dr. G. Gore, 14.
Electro-Magnet, Formulæ of, by S. P. Thompson, 184, 494.
Electromagnet, Law of, 47, 336.
Electromagnets, Lifting Power of, by S. Bidwell, 136.
Electromagnetic Induction, by O. Heaviside, 8, 88, 128, 212, 252, 296, 316.
Electro-Magnetic Rotation of the Plane of Polarisation of Light in Iron, Kundt on, 530.
Electromotive Force Standards, by A. Muirhead, 490.
Electromotive Force of Voltaic Cell, with One Aluminium Electrode, by A. P. Laurie, 260.
Electromotive Force in the Voltaic Cell, Seat of, by Dr. W. Ostwald, 179.
Electromotive Forces, Alternating and Induced, by W. H. Snell, 148, 192, 232, 276, 344.
Electropathy, Measuring Galvanic Currents in, 264.
Emmott and Ackroyd's Fire-damp Indicator, 119.
Engine Indicator, Steam, 12, 66, 129
Equipotential Lines, The Deflection of, and the Variation in the Resistance of Bismuth in the Magnetic Field, by A. Leduc, 338.
Examinations at the City and Guilds Institute, 300, 498, 516.
Examination Papers of Science and Art Department, 141, 157, 266, 496.
Exhibition of Lighting Apparatus at Brussels, 158.
Eyesight and the Electric Light (Leading Article), 430.

F

Field *v.* Bennett, 239, 287.
Finsbury College Special Lectures (Leading Article), 366.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. XVII. FRIDAY, MAY 14, 1886. Price 4d.

NOTES.

Cable Interruption.—The steamship, the "Lady Carmichael," has been sent to repair the fault in the French cable.

The Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 7th inst. amounted to £2,640.

Telephony in Mexico.—The *Economista Mexicano*, of April 22, announces the concession of a privilege for ten years in favour of Mr. James Harris Rogers, for his system of a telephone service.

Gas and Electricity. — We gather from an American contemporary that the gas companies in Brooklyn, New York, have made application to the State Legislature for power to furnish electric light as well as gas.

Great Northern Telegraph Company.—The final dividend of 6s. per share for 1885 is now payable at the company's bankers, Messrs. C. J. Hambro and Son, 70, Old Broad-street, London, E.C., against Coupon No. 6.

The Telephone in Italy. — The Italian Government is doing everything it can to promote the telephone industry, and has recently authorised the erection of a telephone system connecting three villages in the neighbourhood of Genoa.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ended 7th inst. were £1,749, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

The Hanover Square School.—The report of the examiners of this school, just received, announces that the following students have obtained full certificates :—Léon Drugman, E. C. Mozzoni, P. S. Tasker, and A. A. Voysey. The chief examiner was Mr. H. R. Kempe, of the G.P.O.

West India and Panama Telegraph Company.—We are informed that at a meeting of the directors held on May 12th it was decided to place £2,000 to reserve, and to recommend to the shareholders at the approaching meeting that a dividend of 6s. per share be declared on account of arrears of dividend on the first preference shares.

Electric Lighting Bills.—The Select Committee of the House of Lords appointed to consider the Electric Lighting Act of 1882 Amendment Bills, of which three are before the House, is now taking evidence. The Committee, however, resolved that evidence should be taken in private, and the public is therefore excluded.

A Curious Patent.—An electric horse unhitcher has been patented by Mr. Andrew J. Coffee, of Portland, Oregon. Combined with an electro-magnet is a lever, with a stem loosely carrying an armature, a spring for pressing the armature upwards, with other novel features for automatically unhitching horses in engines and truck houses on a given signal.

Press Telegrams to Australia.—A Reuter's telegram from Melbourne says :—The Victorian Government has consented to allow those colonies which do not contribute to the cable subsidy the benefit of the proposed reduction of the tariff for press telegrams between England and Australia. It declines, however, to extend the subsidy to twenty years.

Telephone at Liverpool.—In order that the Queen might listen to the play if she so desired, telephones were affixed to the stage of the Court Theatre, Liverpool, and placed in communication with Newsham House, the residence of the Queen during her visit to Liverpool. "Les Cloches de Corneville" was the opera chosen for Tuesday night, and on Wednesday "La Mascotte."

New Book on Electric Lighting.—Mr. A. A. Campbell Swinton, we are informed, has in the press a small book, entitled "The Elementary Principles of Electric Lighting." It treats the mere elements of the subject in the simplest possible language, and is intended as a rudimentary manual for the use of workmen and non-scientific persons unacquainted with electrical phenomena.

The French Tariff.—The *Standard's* Paris correspondent of Wednesday states that the uniform rate for telegraphing in France is five centimes per word. M. Granet, Minister of Posts and Telegraphs, has just decided that from the 1st of June a reduction of fifty per cent. shall be allowed on all despatches addressed to journals in France. When the Chambers re-assemble he will also lay a Bill on the table for reducing the postage now paid for newspapers.

Electricity and Burglars.—At the Old Bailey on Tuesday, Thomas King, a clerk, was convicted of having committed a burglary on the premises of Mr. Henry Mayer, Museum-street. Mr. Brown prosecuted. The prosecutor was aroused by the ringing of an electric bell in his bed room, and on going downstairs he found the prisoner and another man in the passage.—At Bristol we hear of aid being obtained per telephone by a housekeeper who heard "someone" on the premises.

Telephone Commission in Italy.—We learn from the *Bollatino delle Finanze Ferrovie e Industrie*, of May 9, that the Italian Minister of Public Works has just appointed a commission to hold an inquiry into the telephone systems of Italy and other countries, and their relation to other public works, especially the telegraphs, and further, to propose to the Government such legislative measures as they may think most suitable to regulate the concession, construction, and the working of telephones.

Franklin Institute.—The May number of the *Journal* of the Franklin Institute contains a lecture delivered by Mr. C. J. Kintner on "The History of the Electrical Art in the

Digitized by Google

United States Patent Office," which puts the electrical work of America into a clear and concise form. The supplement to the *Journal* contains further reports of the examiners at the recent exhibition dealing with the applications of electricity to artistic effects, art production, musical apparatus, and electro-medical apparatus.

SINGAPORE.—We have received some details of the first permanent electric light installation at Singapore. The installation is at the Union Hotel, and has been carried out by Mr. E. J. Wells, whose initiative in the introduction of gas, and more recently of electrical methods of illumination, we have before mentioned. The installation comprises only 11 incandescent lamps, lighting a billiard room and a music hall; but it is said to give great satisfaction. A small 1½ horse-power portable engine drives the dynamo.

NEWSHAM HOUSE.—On the occasion of the Queen's visit to Liverpool, Newsham House was lighted by electric light, sixty incandescent lamps being distributed throughout the royal apartments. The fittings were of a novel character, and arranged to harmonise with the decoration of the various rooms. The electricity was run from storage batteries supplied by the Electrical Power Storage Company. The whole of the work was carried out by the Liverpool Electric Supply Company under the superintendence of Messrs. Holmes and Vaudrey.

OUNDLE.—At the recent festivities given in commemoration of Lord Burleigh's return as member for North Northamptonshire the electric light was effectively used There was no public building in the town large enough for the gathering, and Mr. J. W. Smith placed one of his extensive malting rooms at the disposal of the committee. The motive power to drive the dynamo was obtained from the brewery engines, and between 60 and 70 incandescent lamps were temporarily installed to light the ball room, by Messrs. Storey and Son, electricians, of Oundle.

CLUMBER.—With regard to the note which has appeared in some Sheffield papers, and which we referred to last week, the contractors, Messrs. Blakey, Emmott and Co., reply by the subjoined letter, received from the Duke of Newcastle's representative: — "London, 3rd May, 1886. Gentlemen, — We have received the Duke of Newcastle's instructions to express to you his entire satisfaction with the excellent arrangements made by you for lighting the exterior of Clumber House and the ball room with electricity during the recent festivities. The exhibition seems to have given general satisfaction."

"ELECTRICITY ANALYSED."—This is the title of a small pamphlet by William Boggett, in which he maintains that the formula for water is incorrect, and that besides oxygen and hydrogen it contains electricity. Several of our correspondents have been rather hard upon us for permitting letters to appear treating of electrical matters either in a paradoxical or in an unscientific and ignorant manner. We commend this pamphlet to them if they require to see or to approximately understand not what we give publicity to, but what, more frequently, is safely deposited where neither readers nor critics can be offended by it.

PRESENTATION OF MEDALS TO TELEGRAPHISTS.—On Saturday last at the close of the annual inspection of the Queen's Edinburgh Rifle Brigade in the Queen's Park by Colonel Macpherson, C.B., five telegraphists were presented with medals for serving in Upper Egypt and the Soudan. The names of the men were Andrew Isles, Daniel Thomas, Charles E. Gray (Upper Nile), and Thomas Smith and R. W. Newlands (Suakin). The presentation was made by Mrs. Cunynghame, wife of the Surveyor-General for Scotland. The number of volunteers on the ground was 2,196, under the command of Colonel J. H. A. Macdonald, M.P.

NEW YORK.—The cost of lighting by gas and electricity will be seen from the following figures, giving the prices at which the lighting contracts have been taken for the year:— The contracts for lighting different sections of the city of New York for one year from May 1st next were awarded by the gas commission as follows: United States Illuminating Gas Company 70 cents. per lamp each night; Brush Electric Illuminating Company, 70 cents. per lamp; Consolidated Gas Company, $17.50 per lamp per year; Equitable Gas Light Company, $12 per lamp per year; New York Mutual Gas Company, $17.50 per lamp per year; Central Gaslight Company, $28 per lamp per year; Northern Gaslight Company, $30 per lamp per year; New York and New York Globe Light Company, each $25 per lamp per year.

BURMAH.—The telegraph line, Maulmain to Myawady, has been completed, and it is intended to send up telegraph masters and signallers to open offices on the line. Zimmay, we learn, is the frontier station. The Director-General of Telegraphs has decided to make a separate division of Upper Burmah, the work at present being too much for the supervision of one chief superintendent. A telegraph line is to be constructed over the fifty-seven miles of road between Nandgaon Railway Station and Aurungabad, of which it is said that half the cost is to be defrayed by the Hyderabad Government and half by the Berar revenue. We hear that on his return from Mandalay the Director-General of Telegraphs intends inspecting all the railway telegraph offices on both the Irrawaddy and Sittang lines, and if time permits will also inspect the telegraph offices in the division, along with Mr. Hill, the chief superintendent.

A LARGE DYNAMO.—On Thursday last Messrs. Goolden and Trotter, electrical engineers and manufacturers, Bull Green Works, Halifax, tested a large dynamo destined to go, with another one, to H.M.S. "Severn," and being identical with those supplied by the firm to H.M.S. "Mersey." The dynamo, one of the largest seen in this district, is known as a 26-unit machine. Not having enough boiler power to run their two engines—the factory engine and the testing engine—the firm tried an interesting experiment, running the factory (the machinery of which covers three floors) by diverting about an eighth part of the current through another dynamo which was acting as a motor. The new dynamo was worked by the 40 horse-power testing engine, run at a high speed. It will be driven, when on the "Severn," by a six-cylinder compound engine by Willans, of Thames Ditton. Fourteen machines of this type, but not of the same size, have been supplied by the firm to the Admiralty.

BANK LIGHTING.—The Electrical Power Storage Company has lately added to its list of office installations by the lighting of the new premises of the English Bank of Rio de Janeiro, in Moorgate-street, E.C., by 50 incandescent lamps, distributed throughout the building. Power is supplied by a 4 horse-power new type Otto gas engine, fitted with worm gear for driving side shaft. This is found to be a decided improvement over the bevel gearing, and runs more quietly. The dynamo charges 31 15 L type cells, which are capable of discharging at a rate of 30 amperes for nine hours. In the general offices the lamps are fitted on brass standards, which, together with the shades and holders, have been specially designed to meet the requirements of desk lighting, as they screen the glare of the filament from the eye, and at the same time throw the full light on to the desks. The whole instal-

Digitized by Google

lation is being worked by the bank porter, and is giving every satisfaction.

STEAMER LIGHTED BY ELECTRICITY. — The steamer "Gloamin," recently launched from the yard of Messrs. Hall, Russell, and Co., Aberdeen, has now almost completed her outfit. On Monday night the electric lighting apparatus with which she is fitted up was set in operation for the first time by way of experiment. The vessel carries 92 lamps in all, the masthead light and the two side lights displaying a flame of 90 candle-power each, the others being 20 candle-power. The motive power is supplied by a 12 horse-power engine, with a Victoria dynamo apparatus. The principal lights with which the experiments were made were those of the sides, masthead, binnacle, and a number of the lamps in the interior of the steamer. The result was in every way satisfactory. The flame produced was very bright and steady, and threw the light well out all around. In respect of clearness and steadiness it far surpasses the ordinary oil lamps. The lighting of the vessel was superintended by Mr. Alexander Shaw, acting on behalf of Messrs. H. Bennett and Co., Glasgow, who have the contract.

CABLE COMPETITION.—"The reduced tariff," says the *New York Mail*, "for cable business between this country and Europe will go into operation to-morrow. The Commercial Cable Company, which has two cables, will reduce its tariff from 40 cents to 25 cents per word. The Anglo, which has four cables; the Western Union, which has two cables; the Direct and the French Companies, which have each one cable, will all reduce from a tariff of 40 cents to 12 cents a word. Consequently the public may expect that, for a few months to come, or, possibly, years, there will be sharp competition, and, perhaps, lower rates. The Anglo, the Western Union, the Direct and the French Companies—four companies with eight cables—are not only entirely out of debt, but they have a reserve fund of nearly $7,000,000. The Commercial Cable Company has, we are informed, a bonded indebtedness of $3,000,000. Cable business should be very lively with these rates, by which, for a comparatively small sum, important messages may be sent. Some pessimistic persons imagine that this cable war rate must necessarily be for a short time only, but there is no certainty on that point, and at all events the public should utilise it while it lasts."

THE TELEPHONE AND RIFLE RANGES.—Experiments have been carried on at the Browndown Rifle Ranges, Portsmouth, to see the value of the telephone for the purpose of the marker giving the result of each shot by means of that instrument, instead of by the usual course of flag signalling. The experiments thus far have been very successful. The system employed is similar to that arranged for the diving experiments on board Her Majesty's ships "Vernon" and "Excellent." The apparatus for it was arranged—as has been that in this case—by the Western Counties and South Wales Telephone Company. The advantages of this system over the old system are various. In the first place, the click of the rifle can be distinctly heard, which prepares one to watch the target for the mark, and thus relieves the eyes from the constant watching of the white glaring target. Again, the man can give the actual result of each shot, whether to the "right," "left," "above," "below," or a "miss," and give the *exact* result, whereas the flags could give but very imperfect imformation. Mr. Hovell, who has carried out these experiments, thinks that ultimately the system will be universally used, and he will continue his experiments with the object of still further perfecting it.

RECORDING VOTES.—An intricate and interesting machine says the *Electrical World*, which for over two years has stood in one of the committee rooms of the House of Representatives, is to be removed. It has an interesting history. An old gentleman named Crosby, noticing with some degree of annoyance the immense amount of time lost in the calling of the yeas and nays, undertook to invent a machine which could record the votes almost instantaneously by the means of electricity. There were to be electric buttons at each Congressman's desk. The pressure of one recorded yea and the pressure of the other recorded nay upon a printed slip at the clerk's desk, while at the same time an ingenious arrangement moved the hands on the dial on the Speaker's desk and showed at a glance how many votes had been cast on each side. The inventor, after having had an expensive model made, was taken sick, and was compelled to spend nine months in Florida. The next session was a busy one, and he could get no one to listen to a dissertation on the merits of his invention. This year his son fell sick and died, and he was not able to urge upon Congress the adoption of his machine. The Speaker will probably give orders to have the apparatus removed, for it fills up considerable space. Mr. Crosby wanted 75,000 dollars from the Government for his invention.

THE BRITISH ASSOCIATION.—The programme of arrangements for the Birmingham meeting of the British Association has just been issued. It meets on Wednesday, September 1, when Sir Lyon Playfair resigns the presidency, and will be succeeded by Sir William Dawson, C.M.G., F.R.S., the eminent Canadian geologist, Principal of M'Gill College, Montreal. In the permanent staff there is no alteration, except that the new secretary, Mr. A. S. Atchison, assumes full responsibility for the first time in place of Prof. Bonney. The local secretaries are Mr. J. Barham Carslake, the Rev. D. H. W. Crosskey, and Mr. C. J. Hart, and the local treasurer is Mr. J. D. Goodman. The following are the presidents of the various sections:—Section A (Mathematical and Physical Science), Prof. G. H. Darwin, F.R.S.; Section B (Chemical Science), William Crookes, F.R.S.; Section C (Geology), Prof. S. G. Bonney, F.R.S.; Section D (Biology), William Carruthers, F.R.S.; Section E (Geography), General Sir F. J. Goldsmid, K.C.S.I., C.B.; Section F (Economic Science and Statistics), John Biddulph Martin, F.S.S.; Section G (Mechanical Science), Sir James N. Douglass, M.I.C.E.; Section H (Anthropology), Sir George Campbell, K.C.S.I., M.P. Great efforts are being made in Birmingham to render the meeting an unprecedented social as well as scientific success. Already several of the sectional committees have had meetings to organise the work of their section.

THE SUBMARINE CABLE CONVENTION.—A conference of delegates of the Powers who were parties to the Convention of the 14th March, 1884, reassembled at Paris on Wednesday. The British delegates are—Mr. Kennedy, C.B, head of the Commercial Department of the Foreign Office; Mr. Trevor, C.B., Assistant Secretary to the Board of Trade; and Mr. Lamb, head of the Telegraph Branch of the Post Office. Mr. Farnall, of the Foreign Office, will be secretary to the British delegates. An influential deputation representative of the telegraphic interest had an interview on Tuesday afternoon with Mr. Mundella at the Board of Trade. Lord Tweeddale introduced the deputation, which consisted of the Marquis of Tweeddale, Mr. Pender, Sir James Anderson, Mr. Weaver, Mr. J. W. Fuller, Mr. Colmache, Mr. Hesse, Mr. Wells, and Mr. Burt. The proceedings were private. The deputation waited upon Mr. Mundella to obtain for the Submarine Telegraph Companies the privilege of being represented at the Conference to be held this week in Paris to

Digitized by Google

consider the alterations in the International Convention for the protection of submarine cables which were made last year by an Act of the British Parliament. The Foreign Office and Board of Trade acceded to this request, and Lord Tweeddale, Mr. Pender, Mr. Weaver, Sir James Anderson, and other gentlemen representing the different companies interested proceeded to Paris to watch the proceedings of the Conference in the interests of submarine telegraphy. The Congress opened on Wednesday at the Ministry of Foreign Affairs, presided over by M. de Freycinet, who was assisted by M. Granet, the Minister of Posts and Telegraphs. Twenty-four countries were represented. After a speech of welcome to the foreign representatives by M. de Freycinet, the Congress elected M. Felix Granet president, and M. d'Albareda, the Spanish Ambassador in Paris, vice-president. Germany was not represented, but sent a note by the German Ambassador promising adhesion to whatever arrangement may be decided.

THE ELECTRIC ARC.—The resistance of the electric arc, says the *Centralblatt für Electrotechnick*, has been for a long time the object of zealous study. By the work of Edlund, whose results have been verified since by Frölich and Peukert, the presence of an E.M.F. in the arc had become very probable, though no one was able to prove its existence. This so long vainly-sought proof has been given by the ingenious method of Victor *v.* Lang (*Centralbl. f. Elektrotechn* Bd. 7, S. 443). No objections to his method and its results have been made except one lately by Prof. Rühlmann. He says, "It is hardly in accordance with the formula found by Edlund and Frölich that the middle spherical brightness of the arc lights, in which one would expect a proportionality with the product Ei, increases in a considerably stronger ratio than the first power of the current." This objection would be well founded if it were possible to speak of the mechanical equivalent of light. But there is no such equivalent for light as exists for heat, but every kind of ray possesses its own equivalent. It is on this account that in incandescent lamps, within practical limits, the amount of light is proportional to the sixth power of the current, and the electric energy required for a normal candle-power diminishes considerably with the rise in temperature of the carbons. The above objection is consequently not well founded, and the existence of the E.M.F. is not thereby brought into question. The interesting question now is, where is the seat of the opposing E.M.F. As the positive electrode gives the most light probably a large amount of work is done there, and that the fall of potential in the first half of the arc is greater than in the second half. This research has its difficulties, because the probe which you must bring into the arc is exposed to a very high temperature. Thence it is necessary to surround it with tubes of insulating material. Clay porcelain or stealite may be used for the tubes, but the latter two are the better, because they do not melt so readily. The resistance of the probe and its connections should be very great, that the arc light may not be affected by its introduction. So far as the researches hitherto made go the following laws may be taken as substantially correct:—
I. In the arc light there exists an E.M.F., independent of the length and of the strength of the current, of about 39 volts.
II. The resistance of the arc light is proportional directly to the length and inversely to the current strength. The cross section of the arc light is proportional to the current.

SPAIN AND SUBMARINE CABLES.—We notice in the *Revista Telégrafica* of Madrid for May a long and interesting article on the position of Spain with regard to submarine cables, showing that, due to its geographical situation, that country should be an important intermediary between the new world and a great portion of Europe. It strongly insists on the necessity of the construction of direct land lines, in connection with, and exclusively in the service of, those cables which are landed on the Spanish coast, and it believes that were the Government to assure the erection of such lines, many cable schemes now in abeyance for the want of good through communication would be carried out, with the result of a large increase to the telegraph revenue. As an instance, a cable between Cartagena and Malta would certainly be laid were the Government to construct an international land line between Cartagena and Bilbao. Nor would there be much difficulty in obtaining a cable between Minorca and Sardinia, should the Government grant a direct and efficient line to Portugal, as the trade between that country and Italy is a very large one. The article calls attention to the absence of telegraphic communication between the Peninsula and Centa, one of the most important fortified places, and of great strategic value as regards naval operations. It is suggested that it would by no means be difficult to arrange for the laying of this cable were the Government to make certain concessions, such as permission to extend the cable to Tangiers and other ports on the West coast of Morocco, or the payment of a small subsidy, or the guarantee of a moderate interest on the capital employed. It is pointed out that in view of the possibility of the carrying out of the long-talked of scheme of a cable between the Canary Islands and Puerto Rico, the line from Spain to Centa and Tangiers might be continued to the Rio de Oro and the Canary Islands, thus assuring a duplicate communication. Another cable suggested as being important to Spanish interests would be between Cartagena and Oran, for the trade between these places is already very extensive and is increasing, and the number of Spanish colonists in the latter place is large and rapidly augmenting, for it is found that Spaniards can stand the climate much better than the French. Among cable enterprises mentioned as likely to be carried out before long is the scheme, which for some time has greatly interested the German Minister of Posts and Telegraphs, for a direct cable between Emden and Coruña, the idea being to secure a communication entirely independent of any English or French lines.

PHOTOGRAPHY AND ELECTRICITY.—Dr. Boudet, of Paris, in the *Bulletin de la S. J. des Electriciens*, describes the photographic reproduction of the luminous effect of electricity without the intervention of ordinary photographic apparatus. The results recorded originated from experiments in determination of conductivity of rarefied gases. Wishing to photograph the different kinds of sparks obtained, he essayed with ordinary photographic apparatus and obtained very imperfect results. On lately repeating the experiments, he employed another method to obtain photographs of the sparks, by operating directly on the gelatine bromide of silver plate. He says: "A photographic plate being put flat (the sensitive side upward), I placed above it, at a certain distance from one another, two pieces of money, one of five francs, the other of 50 centimes. I charged one of the condensers; then, putting its exterior armature in connection with the piece of five francs, I placed the metal knob of the interior stalk (*i.e.*, what was practically the knob connected with the interior coating of a Leyden jar) on the piece of 50 centimes. The spark immediately passed between the two pieces. I repeated the same operation for each kind of condenser, then I carried the plate to the ordinary baths for fixing and showing. Here are the stereotype plate and the positive proof which I obtained. You see that all the characteristic details of each discharge are there reproduced with the greatest fidelity. My aim was attained." He goes on to say how he tried the same thing with the current and the discharge of a Voss machine, and found

Digitized by Google

that the impress of the coins was reproduced in the photograph of the sparks. On this discovery he placed one of the coins over the centre of the sensitive plate, and moved the other round it while the discharge took place. The result was a photograph reproducing perfectly all the details of the stationary coin. He then placed pieces of thick paper with figures on them, in ink or other black matter, between a metal disc and the photographic plate, and found after the passage of the spark a photograph of the figures on the sensitive plate. He found the effect improved by placing a mirror behind the sensitive plate in this case. He found the current (*i.e.*, a continuous discharge) to act better than sparks. He attributes the effect produced solely to the illuminating power of the discharge. He sums up thus:—"The illumination produced by the electric discharge and reflected by a mirror enables you to reproduce with all details of engraving and drawing any plain object placed over a sensitive plate of gelatine-bromide of silver." He expects soon to reproduce the same effects by means of any brilliant light, whether electric or not.

ELECTRICITY ON BOARD THE "TAKACHIHO KAN."—The magnificent cruiser "Takachiho," built for the Imperial Japanese Navy by Messrs. Sir W. G. Armstrong, Mitchell, and Co., left the Tyne on her voyage to Japan on the 6th inst. This vessel, which is of 3,600 tons displacement and over 7,500 horse-power, is, excepting only her sister ship, the "Naniwa," the fastest and most redoubtable cruiser in the world, her mean speed of 18·8 knots being at present unequalled by any other ship of her class. On each of these vessels (the two are precisely similar in every detail) electricity is well to the fore. The two 25 ton 10in. and six 6in. guns are all fitted with electric firing gear, so that by merely pressing a key in the armour covered tower on the forward bridge the officer in command can fire a simultaneous broadside of five guns. The correct aim is obtained by means of an instrument called a *director*, which is a species of fixed adjustable telescope, the guns being so laid that if fired when a part of the target is visible through the director, the several projectiles will all strike at identically the same place, a point of great importance when armoured ships are being attacked. The ship is also fitted with four tubes for discharging locomotive torpedoes, which are fired electrically from stations on the upper deck in a similar manner to the guns. Each tube has, however, its own director and firing key, and is independent of its neighbours. As regards electric lighting, the two engine rooms, the stokeholes, coal bunkers, magazines, captain's cabins, and chart room are fitted throughout with 16 candle-power Swan incandescent lamps, 108 in all being employed. There are also four arc search lights, each of 25,000 candle-power, two on each bridge. The generating plant consists of four dynamo machines, driven by two of Messrs. Goodfellow and Mathew's compound "triplex" engines. Two of the dynamos with their engine are fixed in the forward part of the vessel, while the other two are placed in the forward engine room, all being below the water line, and beneath the 3in. protective steel deck, which covers all the vitals of the ship. A system of trunk wires between the switch-boards at the two dynamo stations permits of any dynamo being connected to any of the four search light or eight incandescent lamp circuits. The whole of the electric light installation, including search and incandescent light circuits and trunk connections, is wired on the double wire system according to a new and original plan worked out by Mr. A. A. Campbell Swinton, electrician to Messrs. Sir W. G. Armstrong, Mitchell, and Co., by means of which the usual unsightly and costly wood casing is entirely done away with, the wires, great and small, main and branch, being covered with a watertight skin of lead, which sufficiently protects the insulator without further covering. This arrangement, while presenting a particularly neat appearance, has proved very efficient and satisfactory in practice. The entire lighting and other electrical installations have been fitted up by the electrical department of Messrs. Sir W. G. Armstrong, Mitchell, and Co., who built both vessels.

VITAL POLARITY.—The following is an abstract of a paper on this subject by Albert de Rochas in *Cosmos* of April 19th, 1886. The author says that a new scientific fact has been discovered by a great French manufacturer, whose name he does not give. It has been formerly noticed by several observers that there were certain sensitive persons who were incommoded by contact with other persons in particular positions, and that these same persons received a different impression from the north and south poles of a magnet, from the summit and base of a crystal, &c. In the dark they saw gleams of light emanating from the human body, from plants, from the poles of a magnet, &c. In other cases the approach of a magnet and electricity have had a soporific effect. M. D——, by his patience and sagacity, seems to have established a link by which these incoherent observations may be brought within the grasp of methodical science. The following shows the nature of the experiments which serve to throw light on the matter. Let us take one of these sensitive persons fully awake. I touch the external part of his little finger with the positive electrode of a battery, or the north pole of a magnet. At the end of some seconds the little finger is stiffened. The same effect would have been produced if I had touched it with the flower of a plant, an acid, my own little finger, or even with the little finger of his other hand, a piece of gold or silver, &c. If I afterwards touch the same part of the stiffened little finger with the negative electrode of a battery, the south pole of a magnet, the stalk or root of a plant, a basic body, my thumb or his own, a piece of nickel or sulphur, &c., the rigidity ceases. Hence one must conclude that there exists in the first series of bodies mentioned a different dynamide from what there does in the second. It is natural to designate the 1st by the name of positive, and the 2nd by that of negative. This is what M. D.—— has done. By making use of alternately positive and negative bodies, he has succeeded in arriving at the distribution of the dynamides on the human body. The head and trunk are positive on the left side and negative on the right, both before and behind. The arms and the legs are positive on the side of the little finger and negative on the side of the thumb or great toe. Moreover, each finger is polarised in the same manner, so that in shutting or parting the fingers the process is the same as bringing together or parting the discs of a voltaic pile. Animals living or dead have the same distribution of polarity as man. Living or dried plants are positive at the flower end and negative at the root end. A fruit is negative at the stalk end, and positive at the other. Inorganic bodies have only one dynamide, or are as wholes either positive or negative. Any two polarities of the same sign placed in contact (or even simply brought near one another if their energy is sufficient) produce a rigidity or repulsion; two polarities of different sign under the same conditions produce a cessation of this rigidity or attraction. These phenomena are translatable by the different actions which arise at different parts of the body. The author goes on to describe the peculiar effect on certain persons of the contact of flowers, the approach of magnets, the contacts of each other's hands, fingers, &c.

PRACTICAL ELECTRICITY FOR AMATEURS.

Electric Bells and Indicators.

Fixing the Wires. — Electric bells are now used very extensively in all classes of buildings, and the arrangements vary to suit the particular requirements of each case. The use of electric bells in this country has not been so extensive as on the Continent, where it is the exception to find the old style of bells. In many cases electric bells have got into disrepute from bad workmanship and cheap fitting up, many scores of places having been wired with the commonest wire obtainable, *i.e.*, a small copper wire (about No. 24 B.W.G.) covered with cotton and a coat of paraffin. Such wires, especially in new buildings, rapidly decay—in some cases in a few months—besides causing leakages from, and consequent rapid exhaustion of, the battery.

The smallest wire used should not be less than No. 18 B.W.G., covered with gutta percha to not less than No. 11 B.W.G., and a final covering of cotton or tape to prevent chafing the gutta percha. This for damp or cool situations. Where, however, wires are exposed to high temperatures, such as hot water pipes, &c., the insulating substance should be india rubber. It may be urged that this wire is too expensive; but the result of using cheap wires cannot but be injurious to both buyer and seller, and bad wires can only be renewed at great trouble and expense after a building is completed and finished. Good wiring is far more important than good bells and indicators, as they are readily accessible; not that the use of any bad apparatus is advocated. The cost of the first named cotton covered wire is about £2 per mile, and the kind advocated about £7. 10s. per mile.

The practice of putting the wires into zinc tubes (unless of ample size) is not advocated, the best method, wherever it can be adopted, being a channel in the wall with a wooden cover screwed on. The channels provided for hot water pipes should, if possible, be avoided, as also all forcible dragging at the wires (as is commonly done in forcing a number of wires into small tubes), and where wires run under floors in the same direction as the boards, they should be placed in small notches (just to hold the wire) one inch apart nearly in the centre of the floor board. If near the edge the wires may be injured in screwing down the board. As notches weaken the joist considerably if there are several wires, a better plan is to bore a hole two or three inches from the top edge of joist, as this practically does not weaken them at all. Avoid the use of iron or steel staples.

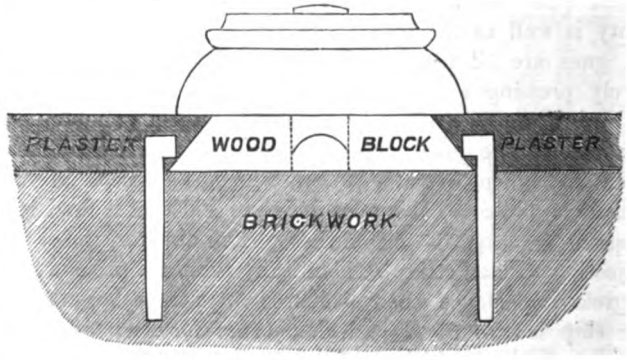
In rooms where there is a push each side of the fireplace it is in most cases preferable to go round over the mantelpiece with the wires (of course sunk in the plaster) to going round or under the hearthstone; the return wire which branches to all the pushes should be of a different colour to that used for the other or outgoing wires, as it facilitates matters in first laying the wires, and in the event of a wire failing there is no difficulty in identifying the wire both at the push and at the battery end. Special care must be taken in jointing the wire at branches, &c.; all joints must be soldered with composite candle or resin—*never use spirits.* When soldered, the joint must be well covered with elastic glue, or rubber tape and then firmly bound over with tape to prevent contact with other wires.

To solder a joint properly without burning up the insulation on each side, the following articles must be provided:—A small spirit lamp, a small copper bit made from about 2 inches of No. 8 copper wire, drawn to a blunt point at one end, with a steel wire screwed into the other end, and this wire driven into a small handle; a small tin box to hold a piece of composite candle or powdered resin; and, lastly, a small quantity of the best blowpipe solder, *i.e.*, tin two parts, lead one part. The copper bit, when new, and at intervals afterwards, will require tinning, which is done thus: Make the bit bright with emery paper or a file, heat it in the spirit lamp, and rub it on a piece of sheet tin with some solder and composite or resin. This should give it a bright tinned surface. Now, to solder a joint, scrape the wires bright, twist them firmly together, rub well over with composite, or dust the joint with resin, heat the copper bit in the lamp, wipe the joint with a piece of rag, touch it on the composite or resin, then on the solder, so that a small piece adheres, and apply it to the joint, rubbing it along. If this is properly done, a strong clean joint is the result.

In removing the covering of any insulated wire never cut square through the covering, but draw the knife parallel with the wire. The first method in all probability makes a slight nick on the wire, and if this is done the wire will break there even if only slightly bent, and consequently cause a fault which may be difficult of access.

In new buildings the position of the pushes should be determined as early as possible, so that the wires may be brought to the appointed places. If tubes are used they should be placed in position before the walls are plastered or floors laid; an uninterrupted run can then be secured from top to bottom of the building. The exact position of the pushes cannot usually be determined until the plastering is done, and the chimney pieces fixed; care must also be taken that the requisite flooring boards are *screwed* and *not nailed down*, so that they may be readily removed when laying the wires. When the position of the pushes is determined, the plaster must be cut away to admit a round, bevelled block of wood (mahogany and elm are very suitable).

This must be set in plaster flush with the surface, the bevelled shape holding it firmly. It is as well, however, to drive two or three floor brads into the joints in the brickwork, the heads embracing the edge of the wood block so as to leave a clear surface to screw on the push. The block should on the face nearest the push be at least ½in. less in diameter, so as to allow the slight adjustment of the latter without exposing the block. The wood is such good fixing that the extra trouble is amply repaid. The annexed sketch will explain the above. On



lath and plaster walls blocks are not necessary, as by using a long slender pricker to find the lath and fine-pointed lath screws a good hold can always be obtained.

Bells.—The bell in ordinary use (Fig. 1) consists of an electro-magnet provided with a vibrating armature, A, carrying the bell hammer, H, a spring, S; the back of this in its normal position comes into contact with a contact post, P. When the current is allowed to circulate in the coils of the electro-magnet the armature is attracted, the hammer thereby striking the bell, and at the same time the spring leaves the contact post, thereby breaking the circuit, thus causing the armature to fall back by the pressure of the spring, which again makes contact with the post, thus causing a rapid vibration of the armature, and consequently the ringing of the bell.

To adjust an electric bell, it will be necessary to see that all the connections are tight, screw post, P, and screw, *b*, firm, and not shaking about; hold the hammer head H against the bell, then adjust the screw *b*, so that it just clears the platinum point or spring. See also that the armature A is quite clear from touching the poles P P. When the hammer is released the spring should draw the armature back, and the platinum point should make *good contact* with the screw *b*. It sometimes happens that a bell rings badly from the spring not setting the armature back strongly enough. In order to know if this is the case, press lightly (with a springy piece of wire) the armature away from the poles whilst the bell is ringing. If the ringing improves the spring and armature must be taken

Digitized by Google

off and the spring *set out a little* close to the fixed end. If the ringing improves when the wire is pressing the armature against the poles the spring is too strong, and must be *set in a little.* The best bells are those mounted on an iron frame independently of the outer wooden case. Never use uncovered bells, as the dust gets into the contact, thus preventing their proper working. See that the contacts are really platinum, and not a white metal, such as German silver, the use of which is very common.

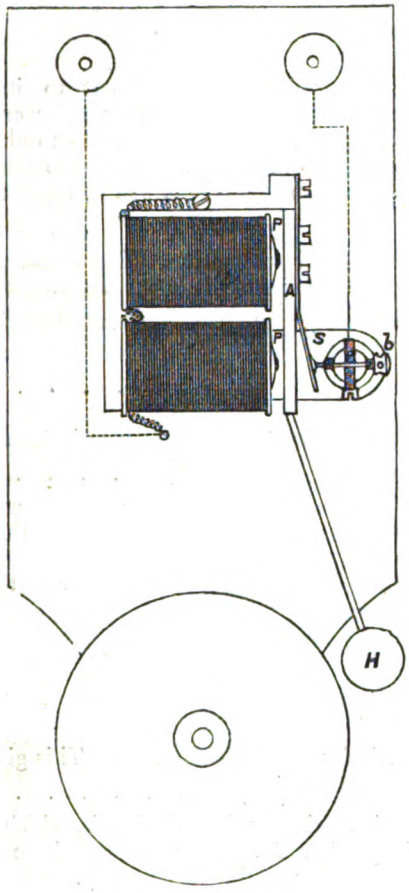


FIG. 1.

Where it is necessary to have two or more bells in one circuit, it is a very great advantage to be able so to arrange

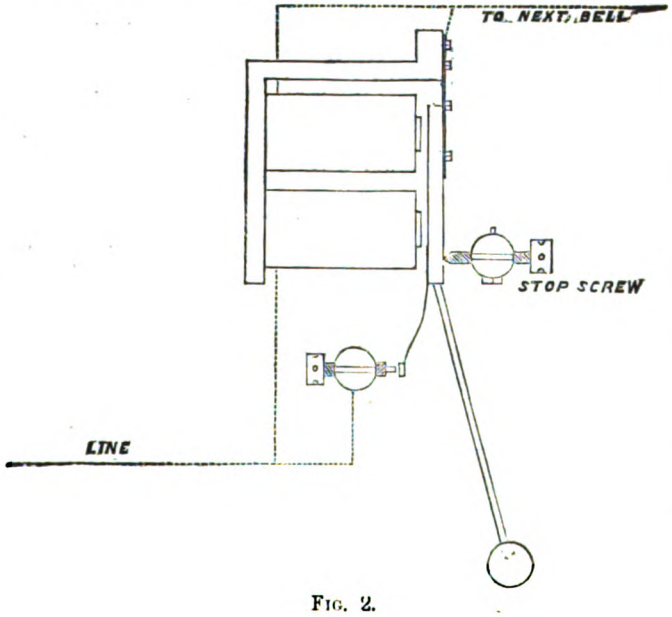

FIG. 2.

them that the ringing of one will not interfere with the ringing of the remainder. This is sometimes attained by employing one vibrating, and the remainder single-stroke bells, the whole being in series. Another plan is to place the bells (constructed as shown in Fig. 2) in series, when each bell governs its own vibrations, not by breaking the circuit, but by shunting its own coils. Directly the armature falls back the coils are again put in circuit and the armature again attracted. Bells arranged in this manner, however, do not ring so energetically as ordinary bells with a corresponding amount of battery power.

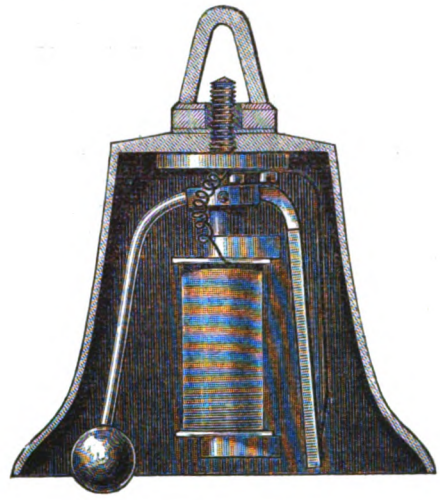

FIG. 3.

Electric bells are now made in the form shown by Fig. 3 A bell in the form of an ordinary church bell is used, having a single magnet of special construction, in which the armature, besides being magnetised by special induction, is directly polarised by being in actual magnetic contact with the iron coil of the magnet; it is thus induced to perform a large amount of work with comparatively small power. It is a very compact and simple arrangement; is by no means unsightly, and the tone pleasant.

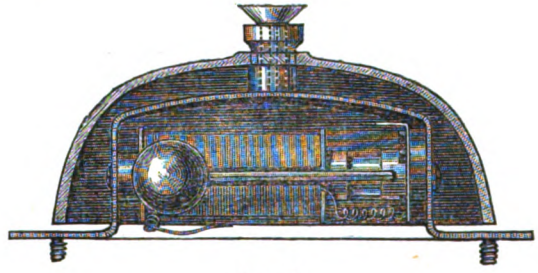

FIG. 4.

Fig. 4 shows a compact form of bell, which is also fitted with a responding attachment, so that a person ringing to a servant

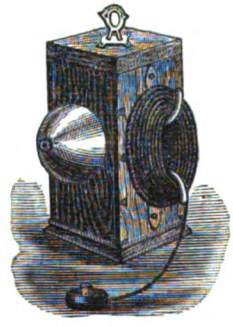

FIG. 5.

can receive (by the servant pressing the button on the bell) an intimation that the summons has been heard and will be attended to.

These modifications are known as the "Jensen System."

For temporary purposes a convenient and portable form of electric bell and battery, with a long flexible silk conducting cord and push, as shown by Fig. 5, is very convenient.

(To be continued.)

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 470, Vol. XVI.)

The Transient State in a round wire with a close fitting tube for the return current.

The propagation of magnetic force and of electric current (a function of the former) in conductors takes place according to the mathematical laws of diffusion, as of heat by conduction, allowing for the fact of the electric quantities being vectors. This conclusion may perhaps be considered very doubtful, as depending upon some hypothesis. Since, however, it is what we arrive at immediately by the application of the laws for linear conductors to infinitely small circuits (with a tacit assumption to be presently mentioned), it seems to me more necessary for an objector to show that the laws are not those of diffusion, rather than for me to prove that they are.

We may pass continuously, without any break, from transient states in linear circuits to those in masses of metal, by multiplying the number of, whilst diminishing the section of, the "linear" conductors indefinitely, and packing them closely. Thus we may pass from linear circuits to a hollow core, from ordinary linear differential equations to a partial differential equation, from a set of constants, one for each circuit, to a continuous function, viz., a compound of the J_0 function and its complementary function containing the logarithm. This I have worked out. Though very interesting mathematically, it would occupy some space, as it is rather lengthy. I therefore start from the partial differential equation itself.

Our fundamental equations are, in the form I give to them,

$$\text{curl}.\mathrm{H} = 4\pi\mathrm{C}, \qquad -\text{curl}\,\mathrm{E} = \mu\mathrm{H}, \quad \mathrm{C} = k\mathrm{E}. \quad . \quad (1b)$$

E and H being the electric and magnetic forces, C the conduction current, k and μ the conductivity and the inductivity. The assumption I referred to is that the conductor has no dielectric capacity. Bad conductors have. We are concerned with good conductors, whose dielectric capacity is quite unknown.

We are concerned with a special application, and therefore choose the suitable co-ordinates. All equations referring to this matter will be marked *b*. The investigations are almost identical with those given in my paper on "The Induction of Currents in Cores," in *The Electrician* for 1884. The magnetic force was then longitudinal, the current circular; now it is the current that is longitudinal, and the magnetic force circular.

The distribution of current in a wire in the transient state depends materially upon the position of the return conductor, when it is near. The nature of the transient state is also dependent thereon. Now, if the return conductor be a wire, the distributions in the two wires are rendered unsymmetrical, and are thereby made difficult of treatment. We, therefore, distribute the return current equally all round the wire, by employing a tube, with the wire along its axis. This makes the distribution symmetrical, and renders a comparatively easy mathematical analysis possible. At the same time we may take the tube near the wire or far away, and so investigate the effect of proximity. The present example is a comparatively elementary one, the tube being supposed to be close fitting. As I entered into some detail on the method of obtaining the solutions in "Induction in Cores," I shall not enter into much detail now. The application to round wires with the current longitudinal was made by me in *The Electrician* for Jan. 10, 1885, p, 180, so far as a general description of the phenomenon is concerned. See also my letter of April 23, 1886.

Let there be a wire of radius a, surrounded by a tube of outer radius b, and thickness $b-a$. In the steady state, if the current density is Γ in the wire, it is $-\Gamma a^2/(b^2-a^2)$ in the tube, if both be of uniform conductivity, and the tube or sheath be the return conductor of the wire. Let H_1 be the intensity of magnetic force in the wire, and H_2 in the tube. The direction of the magnetic force is circular about the axis in both, and the current is longitudinal. We shall have

$$\mathrm{H}_1 = 2\pi\Gamma r, \qquad \mathrm{H}_2 = -2\pi\Gamma a^2(r^2-b^2)/r(b^2-a^2), \quad . \quad (2b)$$

where r is the distance of the point considered from the axis. Test by the first of equations (1*b*). We have

$$\text{curl} = \frac{1}{r}\frac{d}{dr}r,$$

when applied to H.

Now let this steady current be left to itself, without impressed force to keep it up, so that the "extra current" phenomena set in, and the magnetic field subsides, the circuit being left closed. At the time t later, if the current density be γ at distance r from the axis, it will be represented by

$$\gamma = \Sigma\,\mathrm{A}\mathrm{J}_0(nr)\epsilon^{pt}, \quad . \quad . \quad . \quad . \quad . \quad (3b)$$

where Σ is the sign of summation. The actual current is the sum of an infinite series of little current distributions of the type represented, in which A, n, and p are constants, and $\mathrm{J}_0(nr)$ is the Fourier cylinder function. We have

$$\frac{1}{r}\frac{d}{dr}r\frac{d\gamma}{dr} = 4\pi\mu k\gamma \quad . \quad . \quad . \quad . \quad . \quad . \quad (4b)$$

Let $d/dt = p$, a constant, then n is given in terms of p by

$$n^2 = -4\pi\mu kp \quad . \quad . \quad . \quad . \quad . \quad . \quad (5b)$$

We suppose that k and μ are the same in the wire as in the sheath. Differences will be brought in in the subsequent investigation with the sheath at any distance.

In (3*b*) there are two sets of constants, the A's fixing the size of the normal systems, and the n's or p's, since these are connected by (5*b*). To find the n's, we ignore dielectric displacement, since it is electromagnetic induction that is in question. This gives the condition

$$\mathrm{H}_2 = 0, \text{ at } r = b; \quad . \quad . \quad . \quad . \quad . \quad . \quad (6b)$$

i.e., no magnetic force outside the tube. This gives us

$$\mathrm{J}_1(nb) = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7b)$$

as the determinantal equation of the n's, which are therefore known by inspection of a Table of values of the J_1 function.

Find the A's by the conjugate property. Thus,

$$\mathrm{A} = \frac{\Gamma\int_0^a \mathrm{J}_0(nr)\,rdr - \int_a^b \Gamma a^2\mathrm{J}_0(nr)rdr/(b^2-a^2)}{\int_0^b \mathrm{J}_0^2(nr)rdr}$$

$$= 2a\Gamma\mathrm{J}_1(na)/n(b^2-a^2)\mathrm{J}_0^2(nb) \quad . \quad . \quad . \quad . \quad . \quad (8b)$$

The full solution is, therefore,

$$\gamma = \{2a\Gamma/(b^2-a^2)\}\,\Sigma\,\mathrm{J}_1(na)\mathrm{J}_0(nr)\epsilon^{pt}/n\mathrm{J}_0^2(nb). \quad . \quad (9b)$$

giving the current at time t anywhere.

The equation of the magnetic force is obtained by applying the second of equations (1*b*); it is

$$\mathrm{H} = \{8\pi a\Gamma/(b^2-a^2)\}\,\Sigma\,\mathrm{J}_1(na)\mathrm{J}_1(nr)\epsilon^{pt}/n^2\mathrm{J}_0^2(nb); \quad . \quad . \quad (10b)$$

and the expression for the vector potential of the current (for its scalar magnitude A_0, that is to say, as its direction, parallel to the current, does not vary, and need not be considered), is

$$\mathrm{A}_0 = \{8\pi\mu a\Gamma/(b^2-a^2)\}\,\Sigma\,\mathrm{J}_1(na)\mathrm{J}_0(nr)\epsilon^{pt}/n^3\mathrm{J}_0^2(nb). \quad . \quad (11b)$$

This may be tested by

$$\text{curl}.\mathrm{A} = \mu\mathrm{H}; \quad . \quad . \quad . \quad . \quad . \quad (12b)$$

curl being now $= -d/dr$. In the steady state (initial), $t = 0$,

$$\left.\begin{aligned} &\mathrm{A}_0 = \mu\pi\Gamma\{-r^2 + 2a^2b^2\log(b/a)/(b^2-a^2)\}, \\ &\text{in the wire, and} \\ &\mathrm{A}_0 = \{\mu\pi\Gamma a^2/(b^2-a^2)\}\{-b^2 + r^2 + 2b^2\log(b/r)\} \end{aligned}\right\} \quad . \quad (13b)$$

in the sheath. Test by (12*b*) applied to (13*b*) to obtain (2*b*).

The magnetic energy being $\mu\mathrm{H}^2/8\pi$ per unit volume, the amount in length l of wire and sheath is by (10*b*)

$$\mathrm{T} = (\mu l/8\pi)\{8\pi a\Gamma/(b^2-a^2)\}^2\Sigma\int\frac{\mathrm{J}_1^2(na)\mathrm{J}_1^2(nr)}{n^4\mathrm{J}_0^4(nb)}2\pi rdr\epsilon^{2pt}.$$

Digitized by Google

To verify, this should equal the space integral of $\frac{1}{2}A_0\gamma$, using (11b) and (9b). This need not be written. They are identical because

$$\int_0^b J_0^2(nr)\,rdr = \int_0^b J_1^2(nr)rdr = \tfrac{1}{2}b^2J_0^2(nb),$$

so that we may write the expression for T thus,

$$T = \tfrac{1}{2}\mu l\{4\pi a\Gamma b/(b^2-a^2)\}^2 \Sigma\, J_1^2(na)\,\epsilon^{2pt}/n^4J_0^2(nb) \quad (14b)$$

The dissipativity being γ^2/k per unit volume, the total heat in length l of wire and sheath is, if $\rho = k^{-1}$, the resistivity, and the complete variable period be included,

$$Q = \rho\{2a\Gamma/(b^2-a^2)\}^2 \Sigma \frac{J_1^2(na)\,\frac{1}{2}b^2J_0^2(nb)\,2\pi l}{n^2J_0^4(nb)\,(-2p)} \quad . \quad . \quad (15b)$$

When $t=0$, either by (14b) or by easy direct investigation, the initial magnetic energy in length l is

$$T_0 = \mu l(\tfrac{1}{2}\pi\Gamma a^2)^2\left\{1 + \frac{b^2+a^2}{b^2-a^2} - \frac{4b^2}{b^2-a^2} + \frac{4b^4}{(b^2-a^2)^2}\log\frac{b}{a}\right\}, \quad (16b)$$

giving the coefficient of self-induction of length l as

$$L = \mu l[-b^2/(b^2-a^2) + \{2b^4/(b^2-a^2)^2\}\log(b/a)], \quad . \quad . \quad (17b)$$

to be got in other ways. This refers to the steady state. In the transient state there cannot be said to be a coefficient of self-induction, as the distribution varies with the time. The expression in (15b) for the total heat may be shown to be equivalent to that in (16b) for the initial magnetic energy, thus verifying the conservation of energy in our system.

I should remark that it is the same formula (9b) that gives us the current both in the wire and tube, and the same formula (10b) that gives us the magnetic force. They are distributed continuously in the variable period. It is at the first moment only that they are discontinuous, requiring then separate formulæ for the wire and tube, *i.e.*, separate *finite* formula, although only a single infinite series.

The first term of (9b) is, of course, the most important, representing the normal system of slowest subsidence. In fact, there is an extremely rapid subsidence of the higher normal systems; only three or four need be considered to obtain almost a complete curve; and, at a comparatively early stage of the subsidence, the first normal system has become far greater than the rest. In fact, on leaving the current without impressed force, there is at first a rapid change in the distribution of the current (and magnetic force), besides a rapid subsidence. It tends to settle down to be represented by the first normal system; a certain nearly fixed distribution, subsiding according to the exponential law of a linear circuit.

To see the nature of the rapid change, and of the first normal system, refer to *The Electrician* of Aug. 23, 1884, where is a representation of the J_0 and J_1 curves. In Fig. 1, p. 339, take the distance OC_2 to be the outer radius of the tube, O being on the axis. Then the curve marked J_1 is the curve of the magnetic force, showing its comparative strength from the centre of the wire to the outside of the tube, in the first normal system. And, to correspond, the curve vv from O up to C_2 is the curve of the current, showing its distribution in the first normal system.

We see that the position of the point B_1 with respect to the inner radius of the sheath determines whether the current is transferred from the wire to the sheath, or *vice versâ*, in the early part of the subsidence. If the sheath is very thin, so that the radius of the wire extends nearly up to C_2, there is transfer of the sheath current (initial) from the sheath a long way into the wire. On the other hand, if the wire be of small radius compared with the outer radius of the tube, so that the tube's depth extends from C_2 nearly up to O, there is a transfer of the original wire current a long way into the thick sheath. In Fig. 2 on the same page are shown the first four normal systems, all on the same scale, as regards the vertical ordinate, but we are not concerned with them at present.

Since $-p^{-1} = 4\pi\mu kb^2/(nb)^2$,

by (5b), and $-p^{-1}$ is the time constant of subsidence of a normal system, we have, for the value of the time constant of the first system, $-p_1^{-1} = \cdot 273\,\pi\mu kb^2$,

because the value of the first nb, say n_1b is 3·83. Compare this with the linear theory time constant L/R, where L is given by (17b), and R is the resistance of length l of the wire and sheath (sum of resistances, as the current is oppositely directed in them). Let $a = \frac{1}{2}b$. Then

$$L = 1\cdot 128\,\mu l.$$

We have also

$$R = 16l/3\pi kb^2, \qquad \text{therefore } L/R = \cdot 211\,\pi\mu kb^2,$$

so that the time constant of the first normal system is to that of the current in wire and tube on the linear theory as ·27 to ·21. But it is only after the first stage of the subsidence is over that this larger time constant is valid.

We may write the expression for L thus. Let $x = b/a$, then

$$L = \{\mu l x^2/(x^2-1)\}\{2x^2(\log x)/(x^2-1) - 1\},$$

nearly the same as $2\mu l \log x$ when x is large. The minimum is when $b=a$, then $L = \frac{1}{2}\mu l$. This is the least value of the coefficient of self-induction of a round wire, viz., when it has a very thin and close fitting sheath for the return current, so that the magnetic energy is confined to the wire.

When b/a is only a little over unity,

$$L = \{\mu l b^2/(b^2-a^2)\}\{3b^2 - a^2 - 2ab\}/(b+a)^2.$$

We have also $R = lb^2/\pi ka^2(b^2-a^2)$,

and therefore

$$L/R = \pi k\mu a^2[\{2b^2\log(b/a)\}/(b^2-a^2) - 1].$$

Irrespective of b/a being only a little over unity, we have,

with $a/b = \frac{1}{10}$, $L/R = \cdot 009(4\pi\mu kb^2)$,
" $\frac{1}{20}$, " ·053 " ,
" $\frac{1}{40}$, " ·020 " ;

whilst the time constant of the first normal system in all three cases is $\cdot 068(4\pi\mu kb^2)$.

The maximum of L/R with b/a variable is when

$$(x^2-1)(x^3-\tfrac{1}{2})/x^4 = \log x,$$

x being b/a. This value of x is not much different from the ratio of the nodes in the first normal system, or the ratio of the value of r, making $J_1(nr)=0$ for the first time to that making $J_0(nr)=0$. For the latter value makes $\log x = \cdot 465$, and the other side of the last equation to be ·486.

In the subsidence from the steady state, the central part of the wire is the last to get rid of its current. But the steady state has to be first set up. Then it is the central part of the wire that is the last to get its full current. To obtain the equations showing the rise of the current and of the magnetic force in the wire and the tube, we have to reverse or negative the preceding solutions, and superpose the final steady states. As these are discontinuous, there are two solutions, one for the wire, the other for the sheath; but the transient part of them, which ultimately disappears, is the same in both. There is no occasion to write these out.

If the steady state is not fully set up before the impressed force is removed, we see that the central part of the wire is less useful as a conductor than the outer part, as the current is there the least. If there are short contacts, as sufficiently rapid reversals, or intermittences, the central part of the wire is practically inoperative, and might be removed, so far as conducting the current is concerned. Immediately after the impressed force is put on, there is set up a positive current on the outside of the wire, and a negative on the inside of the sheath, which are then propagated inward and outward respectively. If the sheath be thin, the initial (surface) wire current is of greater and the initial sheath current of less density than the values finally reached by keeping on the impressed force; whilst if it be the sheath that is thick the reverse behaviour obtains.

This case of a close fitting tube is rather an extreme example of departure from the linear theory; the return current is as close as possible and wholly envelops the wire current. Except as regards duration, the distributions of current and magnetic force are independent of the dimensions, *i.e.*, in the smallest possible round wire closely surrounded by the return current the phenomena are the same as in a big wire similarly surrounded, except as regards the duration of the variable period. The retardation is proportional to the conductivity, to the inductivity, and to the square of the outer radius of the tube.

When, as in our next section, we remove the tube to a distance, we shall find great changes.

THE SUBMARINE CABLE CONVENTION.

We are glad to be able to announce that, in response to the deputation which waited upon him on Monday, Mr. MUNDELLA acceded to the request of the British Cable proprietors to be represented at the International Conference which formally reassembled at Paris on Wednesday. Lord TWEEDDALE, who took an active part in the debates last year on the Submarine Cable Protection Bill, has accordingly proceeded to the French capital, accompanied by Mr. PENDER, Mr. WEAVER, Sir JAMES ANDERSON, and other gentlemen, to watch the proceedings of the Conference in the interests of the cable companies. It has been one of our complaints against the CONVENTION from the very first that it practically ignores the existence of the owners whose property was under discussion, and gives them no voice whatever in these international decisions. This defect will be partly, though only partly, removed on the present occasion, when it will be no fault of the non-official Delegates if they do not make their presence felt inside the Council Chamber. As on the occasion of the original meeting, two years ago, the British nation is represented solely by Government officials—gentlemen from the Foreign Office, the Board of Trade, and the Telegraph Branch of the Post Office; and although nine-tenths of the cable property of the world belongs to British subjects, and all, or nearly all, of it has been manufactured and laid by British hands, they have no direct voice or vote in the proceedings of the Convention. That the British Government Delegates are not to be implicitly trusted to safeguard the integrity of English property is shown by their acquiescence in international obligations which, put to the test of practical legislation, proved to be either inequitable or unworkable.

It will be in the recollection of our readers that the Paris Convention of 1884 was got together by invitation of the French Government for the purpose of laying down rules for the better protection of submarine cables, for regulating the procedure of vessels employed in laying them, and for the punishment of wilful or culpably negligent breaking of cables already submerged. Some score of nationalities from far and near cheerfully responded to this invitation, the more cheerfully perhaps because most of them had no cable property of their own to regulate. The facts being as we have already stated, and England having an overwhelming interest in this question, one might have thought she would have hesitated to surrender it to the mercy of a majority who were hostile or indifferent to her supremacy. If our Government had declined to attend it, the Convention must have collapsed in the absence of the chief consenting party. But the Foreign Minister of that day was sedulously cultivating the friendship of France, and one way of doing this was to humour her fancy for international pronouncements. Matters might have been worse; the Post Office has very little cable property of its own, and was not particularly solicitous about what belonged to private people. But the Convention, to do it justice, was kept within reasonable bounds, and on the whole tried to do its best for all parties. What it lacked was knowledge of many of the practical issues involved; and also, as it turned out afterwards, of some of the local conditions which rendered their decisions nugatory. In so far as may be now possible to remedy these shortcomings the eminent and experienced men who have gone to Paris in the interests of the great cable corporations may be trusted to do all that can be done.

Whether they can undo some of the mischief already done remains to be seen. Nominally the Conference meets for the purpose of ratifying the stipulations of the 1884 Convention, each party to it having undertaken in the meanwhile to legislate in the sense agreed upon; that is to say, each Government promised to enact laws which would enforce by penalties in their respective countries the regulations agreed upon at Paris. Under some of these regulations, as was shown when the enacting measure was discussed in the Imperial Parliament, any owner or captain of a ship laying or repairing a cable in the proximity of other cables would have to run the risk of imprisonment for a period varying from three months to five years. Culpable negligence was a very elastic phrase; and it was felt to be so more especially in the well-known circumstance that new cables had been wilfully and recklessly laid across older cables, which could not be disturbed without "culpably" damaging the others. The culpability seemed to be altogether with those who ran the risk for the sake of shortening their journey or embarrassing their neighbour's property. It was felt also that the interpretation of this and other provisions of the Convention might depend very much on the country in which a case of negligence is tried. Many attempts were made in the House of Lords—a full report of whose proceedings will be found in *The Electrician* for July 31st, 1885—to amend the English Act so as to make its pro-

Digitized by Google

visions more consistent with ordinary usage and common fair play, and some useful modifications were actually introduced; but it was found impossible to make the Act at once satisfactory to English cable proprietors and conformable to the Articles of the Paris Convention.

It further appeared that in one important particular the English Government were powerless to carry out the spirit of the Paris Convention—or at least professed themselves powerless. A very sensible recommendation was formulated by the Delegates that the respective Governments should exercise some regulating influence over the landing of cables on their shores. The British Government when called upon to act up to this provision declined to do so, on the plea that in many localities the foreshore belonged to private individuals, whose rights could not be curtailed. The plea is ridiculous, for if it is good for anything it would cover the landing of a hostile army. The real objection was confessed by one official apologist when he declared that to interfere with the landing of fresh cables would be favouring the existing cables. But one chief object of the Convention is to "favour" them by regulating and protecting them; and you cannot do either if you permit indiscriminate cable laying. England's laxity in this respect is, in fact, at the root of the whole difficulty, so far as British waters are concerned and for a great way beyond them. On some extravagant application of the doctrine of free competition the Government allow all sorts of dangers and heartburnings to arise, and then calmly propose to inflict heavy penalties if any accident occur that can be construed as culpable. A provisional order ought to be sought for every new cable, just as is required for similar undertakings inland; and in that case, before granting it, suitable conditions would be imposed to prevent fresh complications. A suggestion in this sense was made in the House of Lords, but dismissed as unpopular. Our opinion is that any legislation for the protection of cables will remain ineffectual unless the duty of regulating them is frankly recognised.

CORRESPONDENCE.

OZONE AND OTHER GAS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In common with every reader of your journal with whom we are acquainted, we for some little time looked forward to the perusal of certain effusions appearing in your correspondence columns as a weekly recreation. It has, however, been suggested that the wearing threadbare of the one or two comic ideas may possibly indicate that these fearful and wondrous "facts" and "proofs" (?) are to be looked at in a serious light. The bare possibility of such an idea has struck consternation into many a manly breast, and we feel constrained to ask whether it may not be advisable to label such matter in the business-like way of the German papers "Humoristich ?"—Yours, &c. A AND B.

May 10, 1886.

SABINE *VERSUS* WHITE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I hope you will allow me to correct an error I made in my previous letter to you, and thereby do an act of justice to Mr. J. G. White in America.

In my previous letter I wrote as if the late Robert Sabine had preceded Mr. White in the same line of thought about the covering of electric wires; but in doing so I have erred. Mr. Sabine made two tables for currents from 5 to 90 and from 100 to 1,000 amperes for conductors of bright copper exposed to the air. These tables were first published on January 6, 1883, and reprinted on May 5 of the same year. At the end of the latter publication of these tables is appended this note: "When the conductor is covered with india rubber the rise of temperature will be about 25 per cent. less than the values indicated above." This note implies that to cover a wire carrying a current of electricity is a means whereby the wire may be kept cool, and as this result is in accordance with the results of Mr. White's experiments, I too readily adopted the conclusion that Mr. Sabine had made experiments which led him to write the above note; but on a more careful examination of his published writings I find that the note is a contradiction to all his other writings, and there is no evidence whatever in them to show that he had made experiments with covered and uncovered wires, such as Mr. White has made. That Mr. Sabine, prior to his making out the said tables, did not make experiments on covered and uncovered wires is manifest from his own declaration that the tables "are only tentative, and do not pretend to be strictly exact." In Mr. Sabine's remarks which accompany the first publication of the tables on 6th January, 1883, he enters into theoretical statements about the effect of covering wires, and sums up his opinion in these words:—"The elevation of the temperature of any [electric light] lead is proportional to the obstruction which the insulator offers to the escape of the heat generated in it." Now, this opinion of Mr. Sabine is overturned and shown to be untrue by the results of Mr. White's new experiments, as published by Prof. W. A. Anthony in an American contemporary. As these experiments are not only interesting, but of importance, I send you an extract of Prof. Anthony's remarks on them, in the hope that you may be able to find a corner for them.—Yours, &c.,

8, Merchiston-park, Edinburgh, JAMES JOHNSTONE.
10th May, 1886.

[EXTRACT.]

Prof. W. A. Anthony, writing about experiments made by Mr. G. White, at the Physical Laboratory of the Cornell University, says: "Wires in length of about 100ft., half covered and half naked, of various sizes and styles of insulation, were obtained from the manufacturers. One of these wires being strung up in such a way that the covered and naked portions were equally exposed, a current increasing in strength from one whose heating effect was inappreciable to the largest the wire would bear was sent through the entire length of it, and the resistances of the two portions measured while the current was passing. To provide for the measurement of the resistances the wire was made to form one branch of a Wheatstone balance, the other branches of which were so arranged as not to be heated by the currents that flowed through them. In *every case* the resistance of the naked wire increased much more rapidly than that of the covered, and, in general, the thicker the insulation, the less the increase in resistance. In the case of a 'Clark' insulation, for instance, where the wire was 65 mils., and the covering 285 mils. in diameter, the increase in resistance due to heating by the current was, I think, about three times as much for the naked as for the covered portion. I was myself surprised to find that the effect of the covering to keep the wire cool was the general and not the exceptional effect. In what respect a covered wire differs from a covered steam pipe will appear when the complete account of this investigation is published."

ELECTRICITY *VERSUS* HEAT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I venture to think that Mr. Johnstone has got on some utterly wrong tack in his studies; but to begin a controversy with him on the subject of conduction and radiation of heat and on conservation of energy would be a task which, I think, no one will undertake. He will find the explanation of his newest puzzle given by the late Mr. Robert Sabine himself (whom he quotes), also more fully by Prof. G. Forbes, York Meeting of the British Association; by Sir W. Thomson, Royal Society, Edinburgh, paper on the "Effect of Clothing;" and by Mr. J. T. Bottomley, Royal Society *Proceedings*, June, 1884. I enclose my card.—Yours, &c., A READER.

May 8, 1884.

THE STEAM ENGINE INDICATOR.—XVI.*

BY AMICE.

Compound engines are variously arranged with respect to the relative positions of the cylinders. The most usual arrangements are those having two cylinders, one behind the other, tandem fashion, with one piston rod running through both pistons; and those in which the two cylinders are placed side by side, and have their pistons connected, through the medium of connecting rods, to cranks at right angles, or nearly so. A third arrangement consists of two cylinders placed side by side, the pistons always moving in opposite directions through their connection with cranks at opposite or nearly opposite centres. There are other arrangements of the two-cylinder compound engine; but they are not now in such extensive use. The three arrangements above mentioned are typically shown by the diagrams, Figs. 43, 44, and 45. The tandem engine

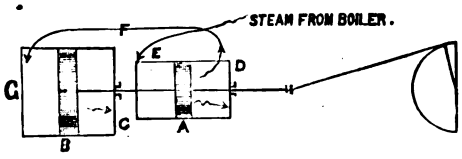

Fig. 43.

is shown by Fig. 43. In this A is the high-pressure cylinder, and B the low pressure. Steam alternately enters at either end of the cylinder A, and is cut off at some part of the stroke of its piston, as at half stroke. Near the end of its stroke exhaust commences, the exhaust steam passing into the cylinder B. In the diagram (Fig. 43), steam from the boiler is entering at the back end of the high-pressure cylinder at E, and exhaust from the front end D of the same cylinder is passing,

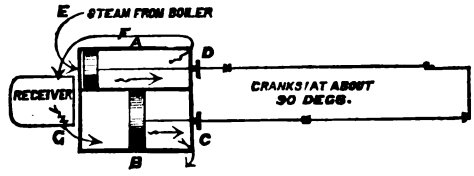

Fig. 44.

as shown by the arrow F, into the back end of the low-pressure cylinder B. An expansion valve must be used for the high-pressure cylinder, but need not be for the low. The pistons are shown as at half stroke, and the crank is is therefore not quite vertical. The rates and direction of movement of the two pistons in this arrangement are, of course, the same; and while the advantages connected with the performance of the expansion in two cylinders are

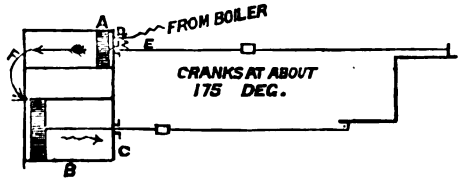

Fig. 45.

obtained, it is a disadvantage, from a mechanical point of view, that the maximum pressure is on both pistons at the same time in the same direction, and therefore also on the crank. The turning moment is subject to the same extremes as with a single cylinder engine, the maximum load on the two pistons acting precisely as though the whole work were done by one piston. It will be observed that the back pressure on the high-pressure piston is always the same as the forward pressure on the low-pressure piston, with the exception of the slight loss due to friction in the steam ports or passages. It may further be observed that the temperature in the high-pressure cylinder will have nearly as great a range as with the single cylinder, or simple expansive engine; but the range is spread over two strokes instead of one. If we follow the steam through one revolution, by the aid of Fig. 43, this will be seen. As shown in the diagram the out stroke is being made as shown by the arrows placed inside both the cylinders. The steam passing from D to G will fall in pressure in accordance with the increase in volume, and the temperature with it, and as the high-pressure cylinder is in communication with the low-pressure throughout the whole of one stroke—that shown as being made—the temperature of the communicating vapour may fall to that of the low-pressure cylinder at the end of its stroke. The cylinder walls are prevented from falling to this temperature by the high-pressure steam the other side of the piston, but, of course, at the expense of the heat of that steam. Thus, with the tandem compound engine without a receiver and cut off valve, the effect of communication with the low-pressure cylinder when the steam has reached its minimum temperature is not avoided, and one of the chief objects of the compound system is only partly realised. On the other hand, the back pressure on the high-pressure piston falls to that of the lowest pressure in the low-pressure cylinder.

In the arrangement shown by Fig. 44 the range of temperature in the high pressure is not so great, and is never greater than that due to the difference between the maximum temperature in the two cylinders. This is effected by causing the exhaust from the high-pressure cylinder to pass into a receiver, as shown by the arrow from D. The temperature of the high-pressure cylinder will thus be not less at any time than that in the receiver. The back pressure in A is, also, never less than that in the receiver. The low-pressure cylinder B receives its steam from the receiver, and is fitted with an expansion valve, or a valve with some lap, by which steam is cut off at less than full stroke, and communication between the two cylinders closed. The difference between the possible efficiency of this form of engine and that shown in Fig. 43 is not necessarily very much, but the gain is decidedly in favour of the receiver arrangement shown in Fig. 44. Sometimes no special receiver is made, the communicating passage and low-pressure valve chest being of sufficient capacity for the purpose. As will be seen from the diagram, the pistons are connected to cranks, which are placed on the two arms of a right angle, or at about 90 degrees apart, so that when one piston is at the end of its stroke the other is nearly at mid-stroke. The position of the cranks has some effect on the form of the indicator diagram, and as will be seen hereafter, an expansion valve is necessary for both cylinders. The action of the engine is the same as though it consisted of two distinct engines, the one supplied direct from the boiler, and the other from the receiver, the latter acting to a considerable extent in making the back pressure in the small cylinder more regular than in the arrangement shown in Fig. 43. The low-pressure cylinder may exhaust into a condenser, the engine then acting as though it comprised a high-pressure non-condensing engine and a low-pressure condensing engine.

In Fig. 45 another arrangement of compound engine is shown, in which the cylinders are placed side by side, in some cases with a receiver between, and in some—as is also the case with the arrangement shown by Fig. 44—with no more receiver than is provided by the passage from the high to the low-pressure cylinder and the valve chest of the latter. The cranks are sometimes placed opposite each other or at 180 deg. apart; but in other engines the cranks are placed a few degrees less than this apart, say at 170 deg., so that the engine may be started from any position, the efficient action of the steam not being at all affected. The admission and exhaust of the steam from the cylinders are the same as in the tandem engine (Fig. 43), and, although the pistons travel in opposite directions, the rotative effort on the crank is the same, and the indicator diagram shows the action of the steam to be the same.

These diagrams (Figs. 43, 44, and 45) are sufficient to explain the principle of the compound engine, although other arrangements have been made, but are not general. We may, however, describe some by reference to Figs. 46, 47, and 48.

Fig. 46 shows an arrangement which is classed amongst compound engines, but is a single-cylinder engine in which the expansion is performed in two stages. A hollow piston

* For Art. 15, see *The Electrician*, 12th February, 1886.

Digitized by Google

rod or trunk piston rod is employed, and the connecting rod pivoted therein, as shown. The trunk occupies a large space, and thus reduces the area of the cylinder at the front end to a determinate amount less than that of the back end, and thus makes it suitable for the high-pressure steam. This steam from the boiler is admitted to A, and being cut off at, say, half stroke, is correspondingly expanded. At the end of the stroke the steam passes as indicated by the arrow F to the end B of the cylinder, which not being occupied by the trunk is much larger in area, and serves as a low-pressure cylinder in which the steam already partly expanded, is expanded to the lowest pressure desired. The action of the steam is the same as that in the arrangement shown at Fig. 45, and the indicator diagram the same. It is an arrangement in which the temperature in the cylinder varies between the same extreme as in a simple engine, but, as in Fig. 43, the variation is

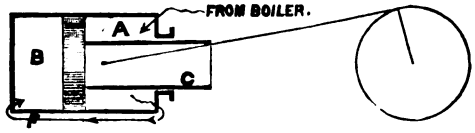

Fig. 46.

spread over two strokes instead of one, and to this extent the arrangement is supposed to secure a possible economy not thought attainable by the simple engine. The use of the trunk is not, however, advisable, as it not only provides a considerable condensing medium in consequence of its being half its time out of the cylinder, but the friction of so large a gland as is necessary to make it tight, is heavy.

Fig. 47 shows an arrangement in which the steam from the

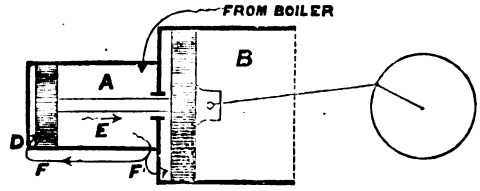

Fig. 47.

boiler enters the front end of the high-pressure cylinder, as shown by the arrow. When the stroke is completed the steam is exhausted simultaneously from the front end of the cylinder A into the back ends of both A and B cylinders, as shown by the arrows F and F'. The high-pressure piston thus performs the stroke, in the direction of the arrow E, in equilibrium, the pressure on both sides of it and on the low-pressure piston being the same, the low-pressure piston

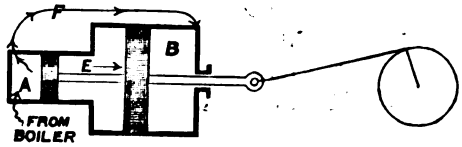

Fig. 48.

performing the work by virtue of its greater area. The front face of the piston in B is open to the atmosphere. It will thus be seen that the high-pressure steam from the boiler does not work against any back pressure, but the low-pressure piston has the atmosphere against it. If the end of the cylinder B were closed, as indicated by the dotted line, the tandem engine of Fig. 43 would be repeated.

Another form of engine is shown at Fig. 48. In this the steam from the boiler enters at A, drives the piston in the direction shown by the arrow E, and when it arrives at the end of the stroke, the steam is exhausted or passes from A to B, as shown by the arrow F. In the arrangements shown at Figs. 46 and 47 only one slide valve, double ported, is required, and it is possible to do with only one for Fig 48.

In our next article we shall give typical indicator diagrams from engines of the several arrangements described.

(To be continued.)

IMPROVEMENTS IN MICROPHONES.

It is stated in the April number of the *Elek. Zeit.* that a microphone with only one carbon must only have a very weak current sent through it, since otherwise the burning of the carbon makes a disturbing noise in the telephone. The amplitude of swing of the microphone plate, and therewith the change of resistance in the carbon contact, must be much smaller than with microphones with several carbons, since the already weak current cannot be subject to much variation without being broken altogether, which produces a very bad effect. In fact, a small arc is formed between the carbons, and a hissing sound like that of the arc-lamp is heard. One cannot increase the sound by speaking louder without losing distinctness in the receiver. The more carbon contact-pieces are inserted in parallel arc the smaller the resistance becomes, and the greater the current may be without a development of heat taking place at the contacts. Fig. 1 shows the arrangement

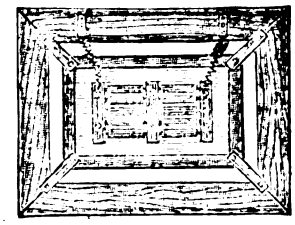

Fig. 1.

Fig. 2.

in the Ader microphone. The plate which bears the carbons is fixed to a frame by four straps of india rubber. This leaves an open space round the plate, and prevents the drum-like sound of a closed box. Fig. 2 shows how the carbons underneath have small pieces of flattened wire to prevent the carbons from twisting round as they vibrate, which would give a rattling sound.

POLLAK'S CELL.

This element consists of a glass vessel, at the bottom of which there is a zinc cylinder 30mm. high, and having a diameter of 75mm. This latter forms one of the electrodes. The other electrode is at the upper end of the glass vessel, and consists of a cylindrical carbon, 80mm. high and 95mm. in diameter, which combines great porosity with good conduc-

Fig. 1.

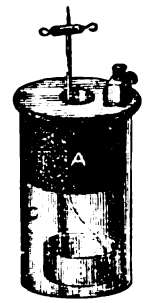

Fig. 2.

tivity, and on whose lower end there is a deposit of electrolytic copper. After both electrodes have been placed in the glass, sal-ammoniac or common salt is sprinkled in, and the cell is then filled with water, which should rise about three or four centimetres above the lower edge of the carbon. The copper form compounds with the sal-ammoniac, which colours the liquid blue. The nascent hydrogen, from the action on the zinc, which is liberated at the copper, decomposes the copper compounds, which are again formed by the agency of the carbon. Thus the element regenerates itself by means of the air in the carbon. Since gravitation plays a con-

Digitized by Google

siderable part in the action, it must be allowed to stand without too much shaking. This element possesses the following recommendations :—It is constant, the materials used in it are cheap, and it requires little looking after.

Two types of cell are made by M. Wehr. The type A is 16½ centimetres high and 11½ centimetres in diameter. Type B is 18 centimetres high and 16 in diameter. The E.M.F. of the cell is 1·3 per volt, with a resistance of from 0·5 to 0·8 ozones. The charge required for a similar size is 200 grammes of sal-ammoniac, for the larger 250 grammes. Figure 1 shows the the cell generally used for telegraphic purposes, A being the cylinder of specially-prepared carbon. B is a cylindrical ring of zinc, carrying an insulated conductor to the binding screw, as shown. Fig. 2 shows the arrangement when the work is more intermittent. The carbon in this case is not covered at the lower part by electrolytical copper, but is said to be impregnated with certain salt, of which the composition has not yet been divulged. B shows the zinc ring, and in both cases C shows the saturated solution.

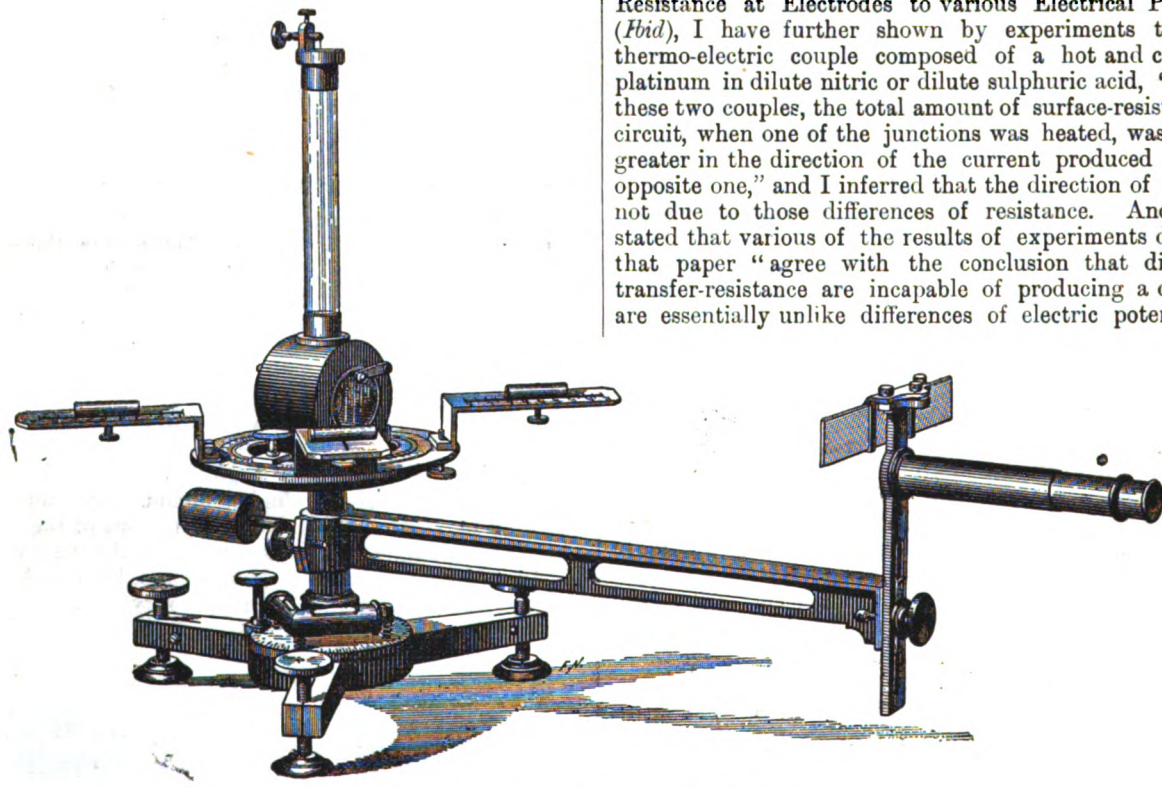
KOHLRAUSCH'S VARIOMETER.

Prof. Kohlrausch's variometer, of which the accompanying is an illustration, as it is manufactured by the firm of Hartmann and Braun, of Bockenheim, Frankfurt, is intended to furnish the physicist and electrician with a handy, cheap, and portable means of estimating variations in the earth's magnetic field ; a determination which, although obviously required for accuracy in many observations, has hitherto only been obtainable at a few large and well-equipped magnetic observatories. It consists of a simple unifilar magnetometer, the magnet of which is a circular disc of steel polished to a flat surface on both sides. It is enclosed in a heavy copper damping box of electrolytically deposited copper, of which material, to prevent local influence, the whole apparatus is constructed. Its special character consists in the fact that instead of a single deflecting magnet there are four, two fixed radially and two tangentially on a cruciform platform, which moves freely round the magnetometer.

A radial arm of some length carries a small milk glass scale, and a little reading telescope in which the image of the inverted graduations of the scale are seen in their correct position.

The small platforms supporting the four deflectors are also graduated, so that an artificial field of any given character can be reproduced, and the variations of the earth's horizontal intensity modified so as to be clearly perceptible in the telescope.

This handy little instrument should be in many physical laboratories besides the great observatories.



Kohlrausch's Magnetical-Intensity-Variometer.

ON "RESISTANCE" AT THE SURFACES OF ELECTRODES IN ELECTROLYTIC CELLS.*

BY G. GORE, LL.D., F.R.S.

In a former paper on "Evidence Respecting the Reality of Transfer-Resistance in Electrolytic Cells" (*Proc.* Birm. Phil. Soc., 1886 ; and *Phil. Mag.*, Feb., 1886, Vol. XXI.) I have shown that the passage of an electric current into or out of an electrode of sheet-platinum by means of dilute nitric or dilute sulphuric acid sets free at the surface of contact of the metal and electrolyte an amount of heat which cannot apparently be accounted for by any other cause than that of an obstacle of some kind to the passage of the current at those surfaces.

And in another paper, "On the Relations of Surface-Resistance at Electrodes to various Electrical Phenomena" (*Ibid*), I have further shown by experiments that with a thermo-electric couple composed of a hot and cold sheet of platinum in dilute nitric or dilute sulphuric acid, "in each of these two couples, the total amount of surface-resistance in the circuit, when one of the junctions was heated, was very much greater in the direction of the current produced than in the opposite one," and I inferred that the direction of current was not due to those differences of resistance. And I further stated that various of the results of experiments described in that paper "agree with the conclusion that differences of transfer-resistance are incapable of producing a current, and are essentially unlike differences of electric potential ;" also, "that heat decreases such resistance whilst increasing contact potential in various metal-electrolyte thermo-electric couples."

Lest it may still be supposed that the phenomena to which I have ventured to apply the term "transfer-resistance" are not really of the nature of "resistance," but are effects due to polarisation, some kind of counter electromotive force, or other form of opposing difference of electric potential, I have further examined, by means of the following experiments, the question whether the phenomenon I have found can exist independently of such difference.

A single conclusive adverse fact is sufficient to upset the most fixed theory ; if the phenomena termed "transfer-resistance" are really due to some form of opposing difference of electric potential, they ought to disappear wherever such difference is absent.

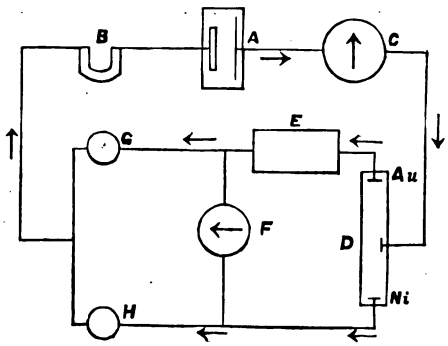
*Read before the Birmingham Philosophical Society, February 11th, 1886.

Digitized by Google

I have tested this point in the following manner:—By the aid of some tables of "Chemico-electric relations of metals in solutions of solts of potassium" (*Proc.* Roy. Soc. 1877, No. 200), and in another on "Some relations of heat," &c. (*Ibid.* 1884, No. 233), I selected cases in which two different metals in an electrolyte produced no voltaic current, and examined those combinations of metals and liquid for any differences of "surface-resistance."

I nearly filled a glass trough, 10·0 cm. long, 2·5 cm. wide, and 3·0 cm. deep, with a solution consisting of about 3 grammes of potassic cyanide (of 92·1 per cent.), and 100 cc. of water. In this solution was immersed, near the opposite ends of the trough, at 8·0 cm. apart, a sheet of nickel and one of pure gold, each being 1·0 × 1·0 cm., not varnished on the back, and connected with a graded dead beat Desprez-d'Arsonval galvanometer (see *Nature*, Vol. XXXI., p. 86), having a resistance of about 150 ohms, and I altered the strength of the liquid until all signs of difference of potential ceased. (The sensitiveness of the galvanometer was very largely increased by substituting for the suspending and connecting wires of silver above and below the movable coil fibres of silk, and making the connections with the coil by means of spirals 3·0 mm. diameter of platinum wire of about ·064 mm. thickness, enclosing the fibres. The instrument was then much more sensitive than an ordinary astatic galvanometer of 100 ohms resistance.)

To test for any difference of "surface-resistance" at the two metals, an electrode of nickel 2·0 × 1·0 cm. was placed in the electrolyte at exactly mid-distance between the end plates, and the following arrangement employed:—



A.—Battery of six pairs of zinc and platinum in dilute sulphuric acid. B.—Regulator of current (see *Proc.* Birm. Phil. Soc., Vol. IV., p. 422. *The Electrician*, 1885, Vol. XV., p. 196.) C.—D'Arsonval galvanometer. D.—Electrolytic trough. E.—Box of resistance-coils = 2,000 ohms. F.—Astatic galvanometer, resistance = 2 ohms. G. H.—Two resistance-coils of 5 ohms each.

The cyanide solution was at 9° C., and the total strength of current employed was = ·00058 ampere, or ·00029 to each end plate. The middle electrode was of nickel. The total current was passed in either direction according to whether the two metals were used as anodes or as cathodes, the bridge galvanometer F being brought to zeroby varying the resistance in E.

When the two end plates were used as anodes, 43 ohms required to be added on the side of the gold plate to restore the balance; and when they were employed as cathodes, 280 ohms had to be added on that side to restore it. The amounts, therefore, of total "surface-resistance" at the gold and nickel plates were in each case very unequal, that of the nickel one being the largest.

As the liquid was not stirred, the "surface-resistance" at each of the two plates included not only what I have termed "transfer-resistance," but also any opposing influence due to polarisation developed by the current. As, however, the reverse current, produced by first connecting the gold and nickel plates with the battery for a time equalling that of duration of the experiment, and then instantly switching them to a galvanometer, was less than one-hundredth the strength of half the total current employed in ascertaining the inequality of "resistance," the opposing effect due to polarisation must have been exceedingly small, and was equal at the two plates. I have already shown in a large variety and number of cases, described in an extensive research, communicated to the Royal Society, March 2nd, 1885, that the "resistance" still exists and varies greatly in amount in different cases, when polarisation is nearly or entirely prevented by employing and rapidly stirring a suitable electrolyte. It may also be remarked that the amount of "resistance" is not directly proportional to that of polarisation, for whilst the opposing force of the latter increases with increased strength of current, "transfer-resistance" decreases.

A second solution, composed of 7·0 grammes of potassic chloride, ·05 gramme of potassic cyanide (of 92·1 per cent.), and 80 cc. of water at 8° C., was tested with plates of gold and iron in a similar manner. The plates were each 1·0 × 1·0 cm., about 9·0 cm. asunder, and not varnished on their backs; the gold was very faintly positive, and this appeared on stirring the liquid. The total strength of current employed was ·0014 ampere, or ·0007 to each plate. The middle plate was of iron. With the two metals as anodes, the iron offered 1,230 ohms less, and as cathodes 26·0 ohms less resistance than the gold.

And with plates of nickel and copper 1·0 × 1·0 cm., 9·0 cm. apart, and varnished on their backs, in a third solution, composed of 1·89 grammes of potassic bromide dissolved in 100 cc. of water at 8° C., the potentials were equal. The strength of current employed was ·00058 ampere, or ·00029 to each metal. The middle plate was of copper. With the two metals as anodes, the nickel offered 650 ohms greater, and, as cathodes, 210 ohms less than the copper.

We know that the contact of two pieces of the same metal with an electrolyte of uniform temperature produces no difference of potential. I therefore took two electrodes of sheet platinum, varnished on their backs, one being 1·0 × 1·0 cm., and the other 2·0 × 5·0 cm., and 8·0 cm. apart, in the solution of potassic bromide at 8° C.; no current was produced. I measured their amounts of "surface-resistance" in the same manner, by means of a middle plate of platinum, and a total current of ·00058 ampere. As anodes, the "resistance" of the large one was 140 ohms less, and, as cathodes, 23 ohms less than that of the small one.

And in another similar experiment with plates of copper, one being 1·0 × 1·0 cm., and the other 2·0 × 5·0 cm., 8·0 cm. apart, and varnished on their backs, with a middle plate of copper, in a solution composed of 1·0 gramme of glacial phosphoric acid and 10·0 cc. of water at 8° C. As anodes, the "resistance" at the surface of the large one was 50 ohms less, and as cathodes 249 ohms less than that at the small one.

In the first three of these combinations, difference of "surface-resistance" was obtained by employing plates of different kinds of metal, and in the two last by using ones of different sizes. I have already stated (*Proc.* Roy. Soc., 1885, No. 236, p. 209) "that this resistance varies largely in amount with different metals in the same solution;" also, that "the usual effect of diminishing the density of current alone, by enlarging one electrode only, was to diminish the resistance at that electrode."

The results of each of these ten experiments show that the influence which opposes the current at the surfaces of metallic electrodes in electrolytes exists independently of counter-electromotive force, polarisation, and all other forms of electric potential, and is therefore a distinct phenomenon, and cannot be due to those causes.

The magnitudes of "surface-resistance" at each plate of different metal in the first three liquids were also separately measured, by means of an ordinary method with a condenser. The two end plates were immersed, 4·0 cm. apart, in the liquid in a glass beaker, the battery, regulator, D'Arsonval galvanometer, a coil of 200 ohms resistance, and a closed connecting key being in the circuit. A condenser of ·33 microfarad capacity was then connected through a Thomson reflecting galvanometer of 3,040 ohms resistance and a key, with the electrolyte close to one of the plates by means of a wire of the same metal as one of the electrodes, and with the wire circuit near that electrode, and the deflection noted. After discharging the condenser a second deflection was obtained in a similar manner, by means of the potentials on each side of the other plate, and a third by means of those at the

Digitized by Google

two ends of the coil, and the "resistances" calculated from the results.

With the gold and nickel plates in the solution of potassic cyanide at 8° C., and a strength of current = ·00029 ampere, the "resistances" were :—

	As Anode.	As Cathode.
Gold	114 ohms	1,044 ohms.
Nickel	143 „	801 „

With the gold and iron in the mixture of potassic chloride and cyanide at 8° C., and a strength of current = ·0007 ampere, the "resistances" were :—

	As Anode.	As Cathode.
Gold	1136 ohms	768 ohms.
Iron	56 „	360 „

And with nickel and copper in the solution of potassic bromide at 8° C., and a current of ·00029 ampere, the "resistances" were :—

	As Anode.	As Cathode.
Nickel	639 ohms.	1565 ohms.
Copper	130 „	1565 „

The results obtained by this method agree substantially with those obtained by the previous one; there are, however, some considerable discrepancies in the amounts. It need hardly be remarked that in such experiments it is very difficult to obtain perfectly concordant quantitative results by two such different methods, and that it would not be reasonable to expect them. The results uniformly confirm the conclusion that "surface-resistance" may exist independently of all difference of electric-potential.

Equality of voltaic potential, attended by more or less difference of "surface-resistance," may be obtained by a variety of arrangements; and a large number of additional instances might be selected, in which the potentials are equal, whilst the "resistances" are unequal. The ones chosen were preferred because they were convenient and comparatively manageable. Cases of equality of "resistance" accompanying difference of potential might probably also be found.

Is the phenomenon I have detected really of the nature of ordinary electric conduction resistance? If it is, its characters will agree with the most essential ones of that influence. It agrees in several important points with ordinary conduction resistance; first, it is not able to produce a current; second, it is usually small with those liquids in which ordinary resistance is small; and, third, it is considerably reduced in liquids by rise of temperature (*see* "Relations of Surface-resistance at Electrodes," *Phil. Mag.*, Vol. XXI., Feb. 1886). It differs, however, from conduction resistance in the less important circumstance that it varies in amount with the strength and density of the current; with a given electrolyte it is also usually much larger in amount than the ordinary conduction resistance of a short section of that liquid; this appears consistent with the difference of conditions.

From these various fundamental truths respecting it, "transfer-resistance" is a retarding influence essentially similar to ordinary conduction-resistance, but modified, increased in amount, and rendered more complex by taking place at the surfaces of mutual contact of two heterogeneous bodies instead of in the mass of a homogeneous substance; but whether it ought to be designated by some other term than the one I have found it convenient to employ is a question not yet settled. It is my intention, if I am not prevented, to further investigate the subject.

As the magnitude of this "resistance" to that of the mass-resistance in a given electrolytic or voltaic cell is usually large, especially with non-corroded metals, it performs an important part in the action of voltaic batteries and electrolytic cells. One important practical application of the fact that "transfer-resistance" is usually diminished by enlarging the electrodes, has been made in the electro-metallurgical purification of copper on the large scale, where a great saving has been effected by arranging the depositing vats in "multiple series." I have also shown (*Phil. Mag.*, Vol. XXI., 1886, p. 150) that in consequence of diminution of "transfer-resistance" by rise of temperature, with a voltaic element composed of zinc and platinum in dilute sulphuric acid, "the electromotive force was increased about 8·38 per cent., and the strength of current 220 per cent., or to 3·2 times its original amount, by raising the temperature of the platinum negative plate 81·0C. degrees."

EXPERIMENTS WITH OIL AS AN INSULATOR.

BY H. C. FREMPT.

The oil used to insulate the underground wires running into the telephone exchange, at the corner of Broadway and Spring street, New York, is heavier than water. Take two cotton-covered wires which have been boiled in that oil, draw them through glass tubes, twist the ends together, and place them in an ordinary glass battery jar. Fill the jar half full of oil, after which water may be carefully poured into the jar and it will remain above the oil. Attaching the poles of a battery to each of these wires, as shown above the glass tubes, no current will be observed as passing from one wire to the other. See Fig. 1.

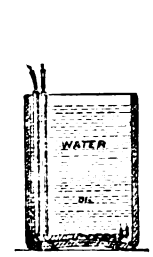


Fig. 1.

Fig. 2.

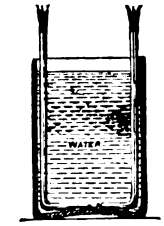

Fig. 3.

Take a piece of lead pipe containing a cable of cotton-covered wires insulated with the same oil in a fluid condition, and cut a hole in the lead an eighth of an inch in diameter, as shown at the point *a*, Fig. 2. The oil being viscous will ooze out slowly. Place the cable in a jar as shown, and fill the jar with water, the oil will continue to flow till an equilibrium is established, but no current can be passed from one wire to the other or from either wire to the lead pipe. Now, if instead of oil we use in this experiment paraffin, pitch, or resin, the insulation immediately fails.

Six years since there was a lead-covered cable insulated with oil, armoured and laid across the Delaware river. The cable contained 50 conductors, not one of which has failed. The cost of this cable of 50 conductors was no more than that of an ordinary gutta-percha insulated cable of five conductors. The gutta-percha insulated cable across the Delaware during this period have been continually subject to mishaps. Many of the conductors have been injured by lightning, although protected by lightning arresters. When the gutta-percha insulation is punctured by atmospheric electricity, it leaves a hole in the insulation in which water enters, by which the current passes to earth. The cable has to be under-run, the leak found, and the hole sealed up; but a hole cannot be made in a liquid. Many of the small streams flowing into the Delaware are bridged with draws to let through passing vessels. Beneath these draws have been placed lead cables, which in some instances have been caught and kinked, as shown in Fig. 3. The strain upon these kinks has been such that if the wire had been insulated with gutta percha or india rubber the insulation would have been destroyed. The combination of lead, cotton, and wire is much less liable to injury from a strain of this nature than the combination of india rubber or gutta percha with the wire as insulated in the usual form.

ELECTRIC LIGHT FOR MADRID.

In continuation of our remarks last week upon the proposed substitution of the electric light for gas in Madrid, we now learn from Spanish advices that the installation is to be carried out by Messrs. Edison, of New York, though no formal contract appears to have been made with the municipal authorities. The *Comercio Español* states that Mr. Perez Valdivieso, Messrs. Edison's representative in Madrid, asked in the first place, as a preliminary, if it were possible to establish a central station of some 300 square metres within about half a mile of the Puerta del Sol. This has been pro-

Digitized by Google

vided. In the second place he asked as to the probability of many users of the light. Nothing positive was stated on this point, but considering the unanimity with which the decision to discontinue the use of gas was arrived at, and the cheapness of the electric light, it was submitted the customers would be numerous.

The third question was with regard to the installation and laying of wires. It was pointed out, on counsel's authority, that the conditions of the existing Gas Company contain nothing to prevent the Ayuntamiento making fresh arrangements for replacing the light by any well-known system, having been in active operation for at least three years, either in Spain or abroad. The Alcalde, or Mayor, has, on this declaration, promised to do what he can to further the wishes of the trading community; but he has expressly stated very clearly that Messrs. Edison must not expect to receive any privilege from the municipality. Privileges, he says, have already cost the ratepayers too much for any fresh ones to be granted, however beneficial they may appear. It is possible rather that the Ayuntamiento may impose a municipal-tax upon the company. As a result of the various interviews, it is stated that the Edison Company has resolved to immediately push forward the installation on a large scale. Cable advices from New York report that six engineers are leaving for Madrid with the necessary funds and material.

THE SPANISH TARIFF AND IMPORTS OF ELECTRICAL APPLIANCES.

The Spanish Customs authorities in Madrid have just given their decision in an appeal against the imposition of somewhat heavy duties upon the import of galvanised iron fasteners for the support of telegraphic insulators. Last year a large consignment of 4,650 kilogrames of these fasteners was made to Santander, and the clearing agent attempted to pass them through the Custom House under section 27 of the Spanish tariff, which runs as follows:—"Wrought iron and steel in bars of any shape, in sheets up to six millim. thickness; axles, tyres, plates, and springs for carriages; and iron hoops—13 pesetas per 100 kilos. for non-treaty nations, and 8 pesetas 65 cents. for treaty nations." The Custom House officials, however, levied duties under section 30, the terms of which are as follow:—"Iron nails and screws although with brass heads—20 pesetas for non-treaty, and 14 pesetas 85 cents for treaty nations. The consignee petitioned the central authorities against this charge, and submitted that section 27 of the tariff ought to be amended so as to include imports of the goods in question. The request has been refused, and the Customs journal, *El Eco de las Adnanas*, has published a Royal Order to the effect that iron screws or nails for supporting telegraphic insulators shall pay duty under section 30 of the tariff. Shipments from this country will therefore have to pay an import duty of about 16s. per 100 kilos., as compared with a charge of about 11s. 10d. per 100 kilos. upon similar goods imported from France or Belgium. Should the arrangement for a *modus vivendi* just arrived at be ratified by the Cortes—and there is little doubt that it will be opposed by the English Parliament—English goods will thenceforward enter Spain on the same terms as those of our Continental competitors. It is to be hoped that the treaty may soon come into operation, as the introduction of electric lighting and of electric appliances generally is making rapid progress both in Madrid and in the Spanish provinces.

ELECTRIC LIGHTING AT EDINBURGH EXHIBITION.

The electric lighting is one of the most important features of the Exhibition, and should render it even a greater attraction after dark than during the day. The installations form the largest thing in the way of electric lighting that has ever been attempted. There can be no doubt that this will draw to the Exhibition a large body of practical electricians, who will have the opportunity of criticising the different systems of lighting in actual work. Power for driving the dynamos is obtained from engines supplied by Messrs. Robey and Co., of Lincoln, Messrs. Adamson and Co., of Manchester, and Messrs. Marshall and Sons, of Gainsbro.'

Perhaps the most attractive display is in the centre corridor, which is entirely lighted by 1,500 incandescent lamps of 20 candle-power each. The lights are controlled by 26 circuits of three girders on each, making a total of 78 girders. The leads are run in such a way that the lamps affixed to each alternate girder may be put out at the same time. In connection with this the switch-board is arranged so that in case of any failure of a dynamo another can be switched in without any change perceptible to the visitors. There are six dynamos and three vertical engines for this section, also two dynamos and one spare engine in case of a break down.

The outside lighting is arranged to be worked by two dynamos capable of running 1,200 lamps of 10 candle-power each. These lamps are supplied by the Edison-Swan Company, and have been coloured red, golden, and blue. There are but two circuits, and the lamps are hung from mast to mast in festoons.

Section C is lighted by thirty-two 3,000 candle-power Gülcher arc lamps, placed four in each court, and suspended by the company's improved raising and lowering counterbalance arrangement. Each arc lamp is worked by an independent switch, so that any number of lamps may be used as desired. The two reception rooms and many of the exhibitors' stalls are lighted by incandescent lamps, suspended either by pendants or fittings as found most suitable, the current being taken from the same dynamo as the arc lamps.

The illumination of the grounds is by thirty-two 2,000 candle-power Gülcher arc lamps, constructed for outdoor work, fitted with clear glass globes and white reflectors. The lamps are suspended in groups of four arranged on high poles, each of which is fitted with a special head gear for carrying the lamps, and to enable them to be raised and lowered as required. Each arc lamp is fitted with a switch, which enables it to be burnt quite independently of the other lamps. The current for working the 64 arc lamps and incandescent lamps is generated by four No. 5 compound-wound Gülcher dynamos of the most improved type.

There is an electric railway in the grounds, which is being well patronised by the visitors.

The lighting arrangements are in the hands of Messrs. King, Brown, and Co., of the Rosebank Electric Works, Edinburgh (under the personal superintendence of the foreman electrician, Mr. Henry Lyon), who have also the arrangements for the electric railway; the Gülcher Electric Light and Power Company, of Battersea Foundry, S.W. (under the personal superintendence of Mr. E. Ingles); Mr. R. Miller, of Glasgow; the Anglo-American Brush Company, of Belvedere-road, Lambeth; and Messrs. J. D. F. Andrews and Co., of Woodside Works, Glasgow.

THE ELECTRIC LIGHTING ACT (1882) AMENDMENT (No. 3) BILL.

Petition against, and in favour of "The Electric Lighting Act, 1882," Amendment (No. 1) Bill by the Institution of Civil Engineers.

1. That in the year 1882 an Act of Parliament was passed to apply to all provisional orders or Acts relative to the distribution of electricity for lighting and other purposes.

2. By Section 27 of the said Act it was enacted that at the expiration of twenty-one years, or such shorter period as might be provided in the Special Act, and within six months after the expiration of every subsequent period of seven years, or such shorter period as might be provided in the Special Act, any local authority within whose jurisdiction the area of the undertaking, or any part thereof, was situated, might require the undertakers to sell their undertaking, or part thereof, upon the terms of paying the then value of all lands, buildings, works, materials, and plant suitable to and used for the purposes of their undertaking, and in the event of non-agreement the price was to be determined by arbitration; but the arbitrator was forbidden to allow any payment in respect of compulsory purchase, or of goodwill, or of any profits which may, or might have been, or be made from the undertaking or of any similar considerations.

3. That the effect of the foregoing conditions has been entirely to stop, during the four years since the Act has been passed, the application of private capital to the distribution of electricity from a central station to householders, manufacturers, shop keepers, and others desirous of receiving it as a source of illumination; it being impossible to find persons of means who would embark their capital in undertakings subjected to such conditions, conditions which must of necessity when enforced—as they would be if the undertaking were prosperous—return to the shareholders only a small portion of the capital which they had invested.

4. That your petitioners embrace among their members persons practising in every branch of civil engineering, which is defined in their charter to be the art of directing the great sources of power in nature for the use and convenience of man, thus including electrical engineering, and that they are desirous—in the interests of industry and of the growth of a new and useful application of science to the purposes of daily life—that electrical lighting should have a thoroughly full and fair trial.

5. There are now before your lordships' house three Bills, Numbers 1, 2, and 3, each of which purports to be an amendment of "The Electric Lighting Act of 1882."

6. Number 3 Bill, the one brought in by Lord Houghton, does not vary the Act of 1882, except by an extension of the time before the compulsory right of purchase would arise, from the twenty-one years of the Act of 1882 to thirty years, with a further period of twelve years should the local authority agree, and by the extension of the recurrent periods of option from seven years to ten years.

7. Your petitioners are convinced that such a measure would not cure the defects of the existing law, and would not be successful in attracting capital to an electric light undertaking, which must be essentially one of development. Unlike the case of the construction of a railway between two points, or of a canal between two points, or of the making of a dock, cases where the work is done as a whole and where the capital is needed, and is called up at once, an electric light undertaking is one wherein, at the outset, only a comparatively small portion of the capital can properly be utilised, and it would not be until after a lapse of years, when persons had been educated to use the electric light, and were willing, for the sake of its advantages, to discard the gas fittings for which they had already paid, and to incur the expense of electric light fittings, that there would be such a large or general use of electricity for lighting purposes as to need the expenditure of further capital.

8. That with such a clause as that proposed by No. 3 Bill—a clause which merely defers the time of compulsory purchase—it would be impossible to obtain this extra capital as needed, because even if, at first, persons would subscribe for a probable enjoyment of thirty years, no one would be found to embark money after the lapse of a few years when the term of enjoyment was so much shortened.

Digitized by Google

9. No. 2 Bill ameliorates Section 27 to some extent, but the Bill (No. 1) now before your lordships' house proposes to repeal the Act of 1882 altogether, and to assimilate the legislation in respect of electric light undertakings to that legislation which of late years has prevailed in respect of gas undertakings, and has proved so beneficial to the public while yielding security of property to those who embark their capital. Bill No. 1 provides that the obligations upon the distributors of electricity shall be the same as those which are imposed upon gas undertakings, that dividends shall be regulated upon the sliding scale, by which there is a direct incentive to the undertakers to sell the commodity at the lowest possible price consistent with a profit, and, further, that all future capital shall be issued under an auction clause, thus ensuring that the consumers shall not be liable to pay any greater amount as dividend than is fairly demanded by the risk of the undertaking.

10. Your petitioners desire to point out that the new industry of electric lighting has been, by the Act of 1882, and would, by the Amended Bill, No. 3, if it were passed into law, be subject to burdens which render it impossible to give a mode of lighting that has so much to commend it a fair chance of development, and therefore prevent the establishment of an industry that would give householders and others an option as to the mode of lighting from an external source of supply, an option they do not now possess.

Your petitioners therefore humbly pray your lordships that the said Electric Lighting Act (1882) Amendment (No. 3) Bill may not be allowed to pass into law, but that the Electric Lighting Act (1882) Amendment (No. 1) may pass into law, and that this petition may be referred to the committee of your right honourable house, to whom those Bills have been referred, or that such other relief may be given to your petitioners in the premises as your lordships shall deem meet.

LEGAL.

Edison and Swan v. Woodhouse and Rawson.

This long-expected trial has at last commenced. The case came on on Monday, May 10, before Mr. Justice BUTT, sitting for Mr. Justice NORTH, in the Chancery Division of the High Court of Justice. We shall give but an abstract of the proceedings till what may be termed the summing up matters and the verdict, which we hope to give fully.

The plaintiff in this action are suing to restrain the infringement of three patents relating to incandescent electric lighting—a patent taken out by Mr. Edison in 1879, a patent taken out by Mr. Swan in 1880, and a more recent patent by Mr. Giningham.

Sir Richard Webster, Q.C., Mr. Aston, Q C., Mr. Moulton, Q.C., and Mr. T. Edward Dove appeared for the plaintiffs; the Solicitor-General (Sir Horace Davey, Q.C.), Mr. Charles, Q.C., and Mr. Murray for the defendants.

Sir RICHARD WEBSTER opened the case for the plaintiffs, and described in general terms the claims of Mr. Edison as being for the combustion of a filament of carbon inside a lamp or globe wholly of glass in an almost perfect vacuum, the carbon filament being fixed into the ends of platinum wire, which is passed through the glass hermetically sealed up. The advantage in the use of platinum is that its rate of expansion under heat is much the same as that of glass. A great feature in Mr. Edison's invention is the mode in which he produces a filament of carbon; that is to say, he carbonises a filament instead of doing what had been attempted before, paring down a carbon stick to the smallest possible size. Sir Richard Webster said that this was a thing which no one else had ever thought of, and it had made practical the use of a high resisting medium of very small superficial area for the purpose of incandescent lighting, and thus allowed the multiple arc system of transmitting the current, by which system alone a satisfactory mode of distribution has been able to be used. Mr. Edison made no claim for any particular mode of producing the extremely rare vacuum he requires. The production of such a vacuum would, of course, have been impossible but for the invention of the Sprengel air pump in 1873. Mr. Swan's claim is for an improved mode of obtaining a better vacuum, by which he gets rid of the air in the carbonised filament; and the third patent, that of Mr. Giningham, is for a very simple but efficient way of fixing the ends of the filament of carbon into the ends of the platinum wire. The latter are flattened out and rolled into tubes or sockets, and the ends of the filament, which is bent into a spiral or, in the more recent form, into a double twist, are kept in the sockets by the spring or electricity of the filament itself. The defence seems mainly rested on anticipation. The particulars of objection on this point are almost unprecedented in number, being no fewer than 75. Among the most important is a patent taken out by one King, as long ago as 1845, for an incandescent carbon electric light in a vacuum. The vacuum used was the Torricellian vacuum (the best known at the time), that is to say, in fact, the vacuum that exists at the top of a barometer. Among other anticipations set up were certain patents by Lane-Fox, in date slightly before the patent of Mr. Edison's that is being sued upon. Mr. Lane-Fox used platinum and iridium as the substance to be made incandescent, but it was suggested that carbon filaments were within his claim. Another most interesting illustration of the history of this kind of electric lighting in evidence was a lamp made by Mr. Swan, and exhibited by him at Newcastle, in which the illuminant was a thin rod of carbon. Mr. Swan seems to have had no idea of patenting that instrument.

Sir Frederick Bramwell, the first witness for the plaintiffs, was examined by Sir Richard Webster. He described his view of the nature of the inventions of the plaintiffs, and said he had gone through all the alleged anticipations, and in none of those could he find any anticipation of the merits claimed, and that, from his knowledge of the subject otherwise, he was able to say that the matters claimed were new.

He was cross-examined by Mr. CHARLES, Q.C., and his cross-examination was not concluded at the rising of the Court.

On Tuesday the cross-examination of Sir Frederick Bramwell was continued by Mr. Charles, Q.C.; he was re-examined by Mr. Aston, Q.C. Dr. Hopkinson, the plaintiffs' second witness, was then put in the box, and examined in chief by Sir Richard Webster, Q.C., and he was under cross-examination by Mr. Charles, Q.C., when the Court rose, which happened shortly before the proper time because, as if in comment on the proceedings, the Edison-Swan electric lamps, by which the court is lighted, were switched out. The great endeavour of the cross-examination as regards the Edison patent has been to show upon various specifications, relating chiefly to patents for arc lamps, and from other documents, that the process of getting charcoal filaments by carbonising the filaments was known in the year 1879. With regard to the Swan patent, the endeavour was to show that Mr. Edison had indicated previously the advantage and mode of superexhaustion of the air while raising the temperature of the enclosed carbon material; and with regard to the Giningham patent, to show from its very simplicity that the invention was known to everybody.

On Wednesday the Court was again occupied with the evidence of scientific witnesses on the part of the plaintiffs The cross-examination and re-examination of Dr. Hopkinson were completed; Dr. Fleming, Professor of Electrical Technology at University College, was examined by Mr. Aston, Q.C., cross-examined by the Solicitor-General, and re-examined by Mr. Moulton, Q.C. Mr. John Imray, the well-known patent agent and engineer, was then examined by Mr. Aston, Q.C., cross-examined by the Solicitor-General, and re-examined by Mr. Aston. Almost the whole of the evidence, as on the preceding day, was directed to questions of anticipation of the several inventions the subject of the action.

On Thursday the Court resumed the evidence of witnesses on the part of the plaintiffs, which took up the time of the Court until 1 o'clock. The evidence was chiefly directed, as on the previous day, to questions of anticipation of the various inventions.

The SOLICITOR-GENERAL, in opening the case for the defendants, proceeded to argue that no evidence had been elicited from the witnesses examined to show that the carbon filament of the defendants was made in the way described by Edison. This was particularly notable in the case of Sir Frederick Bramwell, who could not say that the filament was so made, and he (the Solicitor-General) contended therefore that there had been no infringement of the patents in question. He submitted that if his learned friend, Sir Richard Webster, had been able to produce such evidence he would have done so, but it had not been produced, and what was wanted in a case of this kind was proof as to facts, and not statements of opinion. He further contended that the use of carbon filaments was not by any means a new discovery. All that Edison did was to describe a method of using a carbon filament in a way which would make it much more successful in practice—that was to say, by merely using a finer filament than had been adopted previously. He proceeded to describe the antecedent publications of King in 1845, who used a carbon conductor; of Roberts, who also described the use of a carbon burner, and of Swan, who in 1878 gave a description of his lamp, which contained a carbon filament, or carbon pencil, which differed from Edison's only in point of thickness, and further pointed out that Mr. Lane-Fox and Prof. Tyndall both stated that to have a successful burner high resistance was necessary; and to get high resistance it was essential to have the conductor as small as possible. He maintained that if all the world had the right to use carbon burners in a lamp of the description given by Edison, every kind of carbon burner must necessarily be included. If the Swan lamp was known to all the world, how could they prevent any person from making Swan's carbon burner of a finer material, or substituting any other he might think fit, there being no novelty in the mode of making the carbon burner? He next proceeded to point out that the whole question turned upon what was a filament, and said that he would adduce evidence to prove that Swan's lamp, which was described after the date of Edison's patent, contained a carbon conductor—in other words, that the burner was a carbon pencil, and was simply the application of a well-known principle.

The Court then adjourned for the day.

COMPANIES' MEETINGS.

Brazilian Submarine Telegraph Company (Limited).

The twenty-fifth ordinary general meeting of the shareholders of the Brazilian Submarine Telegraph Company (Limited) was held at the Cannon-street Hotel, London, E.C., on Wednesday, the 12th May, under the presidency of the Right Hon. Viscount Monck.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the last ordinary and extraordinary meetings, which were confirmed. The report of the Directors was taken as read.

The CHAIRMAN stated that the report told them almost everything that he could tell them. They would observe that all their property was in good condition, their cables were working efficiently, and they had enjoyed in the past half year—and he was happy to say up to that moment — immunity from accident, which had diminished their expenditure compared with the previous half year by the sum of between £6,000 and £7,000. These were the favourable features—the bright side of the picture; but he was sorry to say that they would also have observed from the returns given of the income of the Company that they were not in the same flourishing state, in a pecuniary sense, as they had been in the habit of being. Their income

Digitized by Google

had diminished in the half-year they were now considering; but there were causes in operation—which they might hope would cease—which accounted for that. There had been an unhappy monotony in almost every company of a commercial character, the chairmen having had to refer to the depressed state of trade for several years past. Very curiously their own Company was not affected up to about a year ago, and their income went on growing; but now they seemed to be sharing with other companies, and similar enterprises to their own, the effect of the depression, and their income had been reduced. There was another reason for the reduction in their own case—namely, the state of exchange between this country and Brazil. A good deal of their income was collected in Brazil, which, of course, they were obliged to transmit here, and if the exchange was against them they suffered. That state of things had, however, improved. An improvement in the value of the milrei had taken place, and was continuing, he was happy to say, and so far that cause would cease to affect their income to a certain extent. They were also suffering from a certain amount of competition on the part of the West Coast Company, which, of course, they could not avoid. They could only meet it in the best way they could; but they were now engaged in negotiations—which it would not be wise further to enter into—for consolidating and improving their position in Brazil, and which would, to a great extent, get rid of difficulties of that kind. He did not think there was anything in the accounts which called for any remark from him. He would be glad to answer any questions which might be asked. He concluded by proposing the adoption of the report and accounts.

Sir THOMAS FAIRBAIRN, Bart., seconded the motion.

Mr. W. GRIFFITH thought the Chairman had presented them with a somewhat gloomy picture of the past half year's working. He wished to know whether, since the beginning of the present half year, the falling off in the receipts had continued. If the dividend should fall below 6 per cent. per annum he trusted that everything possible would be done to reduce the expenses. The Chairman had stated that the exchange had improved, but he could not understand how they could be affected by this matter. He also asked for further information regarding the African Direct Company — the amount of debentures issued and the prospects of that company? He would also like to know more about the negotiations to which the Chairman had referred, and whether the Western and Brazilian Company were parties to the proceedings.

The CHAIRMAN, in reply, said it was obvious that if they had to turn milreis into pounds sterling in order to transmit the money home, they must lose by the conversion, if Brazilian money bore a less value than English money. That was how they were affected by the question of exchange. As to the African Direct Company, he thought that question was fully discussed at the meeting last January. Up to the present nothing had been done beyond proceeding with the construction of that line of telegraph, and they could say nothing more than they could last January as to the probable results in a pecuniary sense. Those who were best qualified to judge thought it might be profitable for the Company. The traffic from the West Coast of Africa would pass over their lines, and they would have whatever benefit was to be derived from that. The negotiations he had alluded to were in progress, and he believed they would result in very great advantage to the Company; but beyond that he hoped the meeting would not ask him to go. He did not think the shareholders had any reason to regret the confidence which they had reposed in his colleagues and himself for the last twelve or thirteen years. The general object of the negotiations was to consolidate and improve the position of the Company. Before any arrangement was finally concluded the opinion of the shareholders would be taken. As to Mr. Griffith's other question, he was sorry to say that the traffic did not show any recovery yet.

The resolution was adopted.

On the motion of Mr. LEWIS WELLS, seconded by Mr. JOHN ANDERSON, a vote of thanks was passed to the Chairman and Directors, and the proceedings then terminated.

Submarine Cables Trust.

The fifteenth ordinary annual meeting of the certificate holders in the Submarine Cables Trust was held at the offices of the Trust, Winchester House, No. 50, Old Broad-street, on Tuesday, the 11th inst., Mr. John Pender presiding.

The SECRETARY (Mr. Lewis Wells) read the notice convening the meeting, together with the minutes of the previous meeting. The report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, the actual revenue of the Trust for the year ending April 15th, 1886, amounted to £18,838, as against £23,493 for 1885. This falling off of £4,655 is explained in the report as having been caused entirely by the diminished dividends paid by the Anglo-American Company, in consequence of the Commercial Cable Company having forced the Atlantic Companies to reduce the tariff from 2s. to 1s. 8d. per word. As it required £21,635 to cover our coupons and expenses, it is evident that but for the large balance brought into the accounts from the previous year and the accidental circumstance of our having five quarterly dividends from the Eastern Extension Company to deal with, we should not have been able to pay our coupons in full. Practically, we began our last financial year with a balance of £4,937, and we carry forward £2,140. Now, gentlemen, that is precisely the state in which we stand at the present moment. As to our future, a great deal depends upon how long the fight will continue in the Atlantic. I hope common sense will come to the rescue soon, and that we shall not be obliged to go on working at an unremunerative rate, but that some arrangement may be come to whereby the public and the shareholders will be equally and fairly served. We should be very glad to find as a Trust for telegraph shares that the tariff which is reduced to 6d. would fill the Atlantic cables. If it did fill the Atlantic cables, there could be no doubt that a very much lower rate than that which has been current of late years would be the permanent rate. But as far as our experience has as yet gone, we cannot say that the present rate is likely to be a permanent one. I hope that before we meet again this question will have been settled, and that we shall be working at something like fairly remunerative rates so as to enable us to continue to pay our coupons in full. With these remarks I beg to move, "That the report and accounts of the trustees now submitted to the meeting be approved and adopted."

Sir DANIEL GOOCH, Bart., seconded the resolution, which was carried unanimously.

On the motion of Mr. FORD, seconded by Dr. PRESTON, the auditors, Messrs. John G. Griffiths and John Gane, were reappointed, and a vote of thanks having been accorded to the chairman and trustees, the proceedings terminated.

Great Northern Telegraph Company of Copenhagen.

The annual general meeting of this Company was held at Copenhagen on the 21st April, F. Zahle, Esq., in the chair.

The CHAIRMAN of the COMPANY (C. F. Tietgen, Esq.) addressed the meeting with regard to the general business during the working year of 1885, and, referring to the state of the Company's cables, said that although the Directors that evening would have the pleasure to report satisfactorily about the results of the year, there was not much to say under this heading. The usual interruptions of the cables, which could not be avoided, had again occurred; but having in themselves at no time been of an alarming nature, the repairs had, thanks to the efficiency of the Company's two repairing steamers, the "H. C. Oersted" and the "Store Nordiske," stationed respectively in Europe and in the Far East, and thanks to the efforts of the Company's excellent staff, been most speedily effected. During such interruptions the traffic of the Company had in no way suffered, as the duplication system of the Company had provided the means for supplying a ready outlet for the traffic which had originally been intended for the line interrupted for the time being. The only drawback of these repairs had been, as must always periodically occur, that the stock of spare cable used for repairs had to be replenished, and the Company had therefore incurred an expense by ordering a new supply, the comparatively small cost of which had been included in the amount shown in the balance-sheet as deducted from the reserve fund. The Northern land line, passing through Siberia and connecting the Company's European cable net with their lines in the Far East, had in May, 1885, been interrupted for a fortnight, in consequence of inundations caused by the breaking up of the ice. These interruptions had in late years been very unusual, and the strenuous efforts which are being made to prevent such occurrences would guarantee against them in future. The traffic receipts had been highly satisfactory, and exceeded—theoretically, at least—the receipts in the prosperous year of 1884. Practically this excess, and more even, had, however, unfortunately been absorbed by the loss of exchange on remittances. As the shareholders would be aware, the Company collected their rates in the Far East in Mexican dollars, and whilst ten years ago about 4s. 3d. could be remitted for a dollar, the Company now barely received 3s. 4d. Considering that more than half a million dollars was annually remitted in this manner, a heavy loss would therefore naturally result, and the large amount figuring on the debit side of the profit and loss account was thus explained. The great event of the year had been the International Telegraph Conference, which had been assembled at Berlin from the 10th August to the 17th September. Without entering into the details of different measures which had been laid before the Conference, he would at once refer to the proposal of the German Administration with regard to the introduction of a uniform international telegraph tariff between any two countries within the limits of Europe—a project which had already been before the previous Conference held in London in 1879. It was brought up again on this occasion; but although it would be impossible not to admire the large views and noble sentiments upon which the conception of this idea was based, it would have been equally impossible to overlook the fact that, if carried out practically, it would have resulted in ruinous pecuniary losses, not only to a large portion of the Government Administrations concerned, but also, and much more grievously, to the private Companies in whose hands are now nearly all the international cables in Europe. Although the measure did not pass in its entirety, the tendency of the original proposition had been so strong that in the result serious tariff reductions were adopted, and notably as regarded the telegraph correspondence between the more distant countries in Europe. It would naturally follow that in such circumstances our Company, whose cables carry a very considerable part of the European and extra-European traffic, would have to be prepared to suffer a loss in consequence of the reductions passed at Berlin. To give examples: A message of twelve words (which our experience now showed us to be a fair average of messages transmitted over the Company's lines) from Great Britain to Russia now costs 9s., whereas after the 1st July it would only cost 6s. 6d. The same with regard to China, for which country the rate from this country now is 8s. 4d. per word; whilst after the 1st July next it will only be 7s. 1d., and as the greatest proportion of these rates accrued to the Company we would consequently have to bear the greatest part of the proportion of the reductions. It should, however, gratefully be mentioned that the powerful Administration from whom the proposals for these reductions emanated, as well as other administrations who by their votes contributed to their adoption, had shown the Company every consideration in giving their consent to certain exceptions from the normal rules in favour of the cables. Special and well merited thanks were also

Digitized by Google

due to the managing director, Captain E. Suenson, who had represented the Company at the Conference, and had carried on the negotiations with the greatest ability and care. These reductions would, however, no doubt have the effect of gradually increasing the traffic, and thus, to a certain extent, compensate for the losses which the Company would suffer. But then, again, such an increase of traffic would mean eventual increase of staff and of telegraph lines, and the Company would therefore have to be prepared sooner or later to resort to the reserve fund. For this reason the Directors had thought it right to propose once more to increase that fund in the same exceptional manner as in former years. In reference to the duplication of the line between Russia and Sweden, the Chairman said that in accordance with Conventions concluded with Russia and Sweden, the Company had already now obtained, free of any extra expense, a reserve line between St. Petersburg and Nystad in Finland, and another in Sweden between Grislehamn and Gothenburg. These two lines would be connected by the cable which had been laid by the Company between Sweden and Finland in 1883, and thus constitute a complete and direct line from St. Petersburg to Gothenburg, which would be of great advantage in the transmission of the traffic between Russia on the one side and Great Britain and France on the other side. At the same time, he would mention that the Company was now going to introduce instruments with certain improvements, which, after a fair trial, had shown that by their employment greater speed of transmission could be ensured within the carrying capacity of the cables. The position of the Company would thus be that they would be enabled to meet all requirements in case a considerable increase of the traffic resulted. But, unfortunately, the effect of the continued general stagnation of trade, industries, and navigation, which as regards the Company's revenue is no longer counterbalanced by the effect of political and military movements in the Far East, had already been felt in the amounts of the receipts as shown by the monthly traffic returns published since the beginning of this year. What with this falling off in earnings, and what with that which after the 1st July next would follow from the reduction of the rates, it could be foreseen that the Company's future income, and particularly that of the present year, would be considerably lower than that of previous years. Thanks to the further addition to the reserve fund, and to several other measures taken during previous good years, it could, however, be hoped that the exceptional circumstances referred to would not tend to diminish the dividend hitherto paid to the shareholders in any sensible degree. The feverish activity which the political events had called forth some years ago with regard to the development of the telegraph net in the interior of China had somewhat abated after the conclusion of the peace between France and China. The fact, however, remained that the telegraph had become a positive necessity for the Chinese, and no fears need therefore be entertained that further developments would be arrested. During the year several lines had been established, of which one of the most important was that which connected Seoul, the capital of Corea, with the Chinese telegraph system. This line, which had been constructed by the Company's engineers, of whom several had entered permanently into the Chinese service, would shortly be extended from Seoul to Fusan, the Japanese Colony on the South Coast of Corea, the landing place of the cable connecting Corea with Japan proper, which the Company had laid in 1883. The Company's instrument workshop at Copenhagen had been well employed, and had latterly received important orders for instruments. A variety of telegraph instruments, manufactured by the Company, had successfully been exhibited at an electrical exhibition at Gothenburg during the month of June. 1885. The balance-sheet, which had been in the hands of the shareholders for some time past, had shown that after all the general charges, as well as the ordinary charges for interest and amortisation of debentures, and the payment of the usual 5 per cent. interim dividend during the past year, had been provided for, there remained an amount of £133,699. 13s. 6d., which the directors submitted to the meeting to deal with as follows :—£45,833 6s. 8d. to be divided amongst the shareholders as an extra dividend of 3 per cent. (making the dividend for the year, including the interims already paid, 8 per cent.) ; £2,777. 15s. 7d. to be allotted to the pension fund for the staff ; £55,555. 11s. 1d. to be added to the reserve and renewal fund ; and £29,533. 0s. 2d. to be carried forward to next year's account. Without discussion the propositions of the Directors were unanimously adopted, the accounts were passed, and the usual discharge was given to the Directors.

L. P. Holmblad, Esq., the retiring director, was unanimously re-elected.

A. Berner, Esq., and Aug. Garde, Esq., were likewise unanimously re-elected as shareholders' auditors.

The proceedings then terminated.

CITY AND GUILDS OF LONDON INSTITUTE.

CENTRAL INSTITUTION, EXHIBITION ROAD, S.W.

PROF. AYRTON, F.R.S., will continue his Course of Lectures on SOME OF THE INDUSTRIAL APPLICATIONS OF ELECTRICITY, on FRIDAY, MAY 14th, at 5 p.m. Subjects : May 14th and 21st, THE ELECTRIC TRANSMISSION OF POWER ; May 28th, ELECTRIC LOCOMOTION.

Persons who have not already joined the Course can do so on payment of a fee of Five Shillings.

PHILIP MAGNUS, Director and Secretary.

ELECTRICAL TESTING DEPARTMENT.

THE SCHOOL OF

ELECTRICAL ENGINEERING & SUBMARINE TELEGRAPHY.

Manager: WM. LANT CARPENTER, B.A., B.Sc., F.C.S.

Inventors provided with Every Facility and the Use of all necessary Plant and Machinery for Testing or working out Electrical Inventions and improvements of Every Description.

The utmost secrecy guaranteed, and advice given as to commercial value of new inventions.

Private Rooms and high professional assistance if required.

TESTS MADE AND REPORTS FURNISHED.

For further particulars apply to the SECRETARY, 12, PRINCES STREET, HANOVER SQUARE, W.

NOTES.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 14th inst. amounted to £2,800.

PHILADELPHIA.—There are now 344 electric lights in the streets and public places of Philadelphia. The city pays 54 cents per lamp per night.

TELEPHONY IN SCOTLAND.—The *Aberdeen Journal* says:—"The National Telephone Exchange Company have arranged to connect Johnstone with Paisley and Glasgow."

PLYMOUTH, PA.—The electric light has met with great favour in this town. There are at the present time 32 arc lamps in use in the streets, and this number will shortly be increased.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 15th inst. are £2,774, as compared with £3,780 in the corresponding period of 1885.

ROYAL SOCIETY.—A paper by Dr. G. Gore, F.R.S., on "The Relations of Transfer-Resistance to the Molecular Weight and Chemical Composition of Electrolytes," was read before the Royal Society at the meeting on Thursday, the 20th inst.

SMALL DYNAMOS AND MOTORS.—Prof. Anthony and Lieut. Murdock have carried out a series of experiments at the Cornell University upon a number of small dynamos and motors. The full report is given in our American namesake.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 14th inst. were £2,230, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

HENLEY'S TELEGRAPH WORKS.—We are informed that the fire which occurred on the premises of this company on the 16th inst. will in no degree interfere with the course of business, the building destroyed being merely a storehouse situated at some distance from the works.

ELECTRIC LIGHTING BILLS.—The Select Committee of the House of Lords on Electric Lighting Bills continues its sittings, under the presidency of Lord Camperdown. Various witnesses have been examined, among others yesterday Mr. George Morrison, town clerk of Leeds.

TEMPORARY LIGHTING.—The electric light was used to great advantage in the Greek plays which took place at Princes' Hall, Piccadilly, at the end of last week. The temporary lighting was admirably carried out by Mr. Montagu Scott. The light was obtained by means of E.P.S. accumulators.

CITY COMPANIES' HALLS.—On Wednesday, the 12th inst., the magnificent halls of the Drapers' Company were lighted for the first time by electricity, the work having been carried out by the Electrical Power Storage Company. There were 212 incandescent lamps used of 20 candle-power.

THE SOCIETY OF TELEGRAPH-ENGINEERS.—The next meeting of this society will be held at the Institution of Civil Engineers on Thursday, 27th inst., when the following papers will be read:—I. "The Telephone as a Receiving Instrument in Military Telegraphy," by Capt. P. Cardew, R.E., member; II. "On a Problem relating to the Economical Electrolytic Deposition of Copper," by Capt. H. R. Sankey, R.E.

AMERICAN INSTITUTE.—The second annual meeting of this institute was to commence on 18th inst., when the officers would be selected. Among the papers to be read are "Recent Progress in Telephony," "Incandescent Lighting from Central Stations," "Secondary Batteries for Light and Power," "Patent Office Practice," "Subterranean Electric Systems," and the "Static Difficulties in Multiplex Telegraphy."

THE CONSOLIDATED.—Our readers will have noticed that another of the electric light companies born in the time when gigantic hopes were rampant has come to grief, and that Messrs. Wheatley Kirk, Price, and Goulty have sold their plant under the hammer during this week. No doubt many have availed themselves of the excellent opportunity to obtain good machinery and appliances under favourable conditions.

PARIS AND GAS.—The report of the Parisian Company for lighting and warming by gas says that the consumption of gas in Paris and the outskirts has diminished. They do not attribute this fact solely to electric lighting, though it no doubt has largely contributed to this diminution. They propose making a special offer of gas for gas engines for working the electric light instead of the cumbersome steam engines. They thus hope to reinstate their trade.

THE "ELECTRA."—According to *The Times* correspondent, the Eastern Telegraph Company's steamship "Electra" has proved of great service in the political crisis in Greece. The "Electra" was chartered by the Government, and the Duke of Edinburgh granted her a pass and all facilities to bring the Grecian deputies from the various islands to the mainland. She brought deputies from Stelytha, Oreos, Volo, Scopelos, Skiathos, and Kumi, and afterwards returned to Syra.

ELECTRIC CONDUCTORS.—A commission has been appointed in France to consider the regulations that should hold good for the installation of electrical conductors. By decree of the 24th April the following gentlemen formed the commission:—MM. Marcel Deprez, Lemonnier, D'Arsonval, and Violet. The commission will prepare rules and fix the technical conditions in order to assure the security of the public in the installation of conductors affecting the transmission of electrical energy.

STATE OF SOUTH KENSINGTON WATER COLOUR DRAWINGS.—An alarming report is current in artistic circles that the water colour drawings at the South Kensington Museum are showing signs of deterioration. Mr. Agnew has taken the matter in hand, and will on Monday ask the Vice-President of the Council to appoint a committee to inquire into it. It is further desired that the committee should report on the best means of exhibiting such works, the best means of conserving them, and the effects (if any) of electric light upon water colour pigments.

INDIAN TELEGRAPHS.—The report of the Telegraph Department for 1884-5 shows that the financial outcome of the year's work gives a return of about 3·3 per cent. interest on capital expenditure. During the year over 6,000 posts and seven miles of cable were added to the system. The Burma-Siam line was completed, and the new cable connection made between India and Ceylon. Great extensions are being made in Upper Burma, and when these are finished the Indian telegraph system will afford means of communication between Bhamo and Quetta, as it does now between Bangkok and Kashmir.

ELECTRIC CAR.—Mr. John C. Henry, of the Henry Electric Railway Company, Kansas City, Mis, writing to the *Scientific American*, says:—"On January 29th I hitched our electric car Pacinotti to a Kansas City, Fort Scott, and Gulf coal car, weighing 17,500lb., and took it up a 2½ per cent. grade. Yesterday I coupled the same motor car to a Chicago, Burlington, and Quincy box car 19,178, weight 24,500lb., and started it without jerking on a 3 per cent. grade. I claim the distinction of being the first to haul regular standard gauge freight cars by electricity, and would be pleased to have you record it."

Digitized by Google

NEW BOOKS.—Messrs. Whittaker and Co. and Messrs. Bell announce in their new "Series of Handbooks for Practical Engineers" Dr. Jul. Maier's book on "Arc and Glow Lamps." It will be a complete handbook on the subject, especially relating to its practical applications, giving the latest results and improvements. The next volume of the same series will be Mr. Gisbert Kapp's "Electric Transmission of Energy," which is promised early next week. Mr. Wm. Anderson has revised and added some new matter to his "Lectures on the Conversion of Heat into Work," which excited much attention when delivered last year at the Society of Arts. They will be published in book form by Messrs. Whittaker and Co.

THE NATIONAL TELEPHONE COMPANY.—Nearly twelve months have passed since the Whitehaven and Workington Exchanges were opened for business. Beginning with 19 subscribers on the list, the number has now increased to 56, an increase of 37. The total number of messages which have passed through the exchanges during this time reach the grand total of 43,757. As the average time taken to transmit each message was about three minutes, and as 300 words can easily be exchanged in that time, it is calculated that no fewer than 13,127,100 have been exchanged between subscribers since the opening of the exchanges. The value of the telephone as a means of communication is now fully understood and fully appreciated by all business men.

DISGRACEFUL CONDUCT.—Mr. P. G. Behn, described as an engineer and electrician, of 72, Queen Victoria-street, City, was charged at Croydon on Wednesday on two summonses with travelling on the London, Brighton, and South Coast Railway without having previously paid his fare, and with intent to avoid payment thereof. Sergeant Potter, of the railway company's police, stated that the defendant was convicted of a similar offence at the Lambeth Police Court on March 18 last, when Mr. Chance fined him 40s. and 23s. costs, that being the full penalty. The Mayor observed that the accused had shown nothing but falsification all through. He had been guilty of a most mean fraud, which was aggravated in every particular. He would have to pay a fine of 40s. and 9s. costs for each offence, in all £4. 18s.

ITALIAN TELEGRAPH STATISTICS IN 1885.—A summary of the working of the Government wires in 1885 has been issued from the General Telegraph Department. The private telegrams transmitted in the interior amounted to 5,896,306, showing an increase of 244,028 compared with 1884, and the messages for abroad 581,657, or an increase of 13,386 on 1884. The Government and service telegrams were 664,358. The number of telegrams received from abroad was 687,423, showing an increase of 22,922. The gross receipts are set down at 13,694,194 lire, say £547,770, and the expenditure at 10,952,048 lire, say £438,080. The total length of the lines on 31st December last was 30,021 kilometres, an increase of 833 kilos. The length of telegraphic wire was 106,755 kilometres.

A MIRACULOUS ESCAPE FROM LIGHTNING.—A Madras telegram to the *Times of India*, dated the 19th April, says:—"Last Friday, Bishop Caldwell and Mrs. Caldwell had a miraculous escape from a stroke of lightning. The Bishop and Mrs. Caldwell were sitting at tiffin in their house at the Pulney Hills, when lightning coming through the iron roof passed through four rooms in succession, causing considerable damage, making a furrow along the ground, and burying itself in a hole which it made. Two servants were knocked down, and one was rendered temporarily insensible. Five persons received shocks; but none were killed. The Bishop and Mrs. Caldwell were surprised to see a ball of fire come between them and seem to explode on the table. Mrs. Caldwell received a slight shock only."

EDINBURGH EXHIBITION.—The Town Council of Edinburgh have lately been considering in committee the desirableness of improving the lighting of the approaches to the Exhibition, and last night a sub-committee visited Brougham-street with the view to ascertaining if some addition to the illuminating power of the gas was necessary. At present, only each alternate lamp is lit in most of the thoroughfares of the city, but the opinion of the committee appeared to be that, on account of the greatly increased traffic in and around Brougham-street, not only should every lamp be utilised, but if possible an electric light should be placed in such a position in front of the Exhibition as will illuminate the surrounding space for a considerable distance. A recommendation to this effect will probably be made to the council at their next meeting.

SOUTH AFRICA.—According to the *Diamond Fields Advertiser*, the electric light played an important part in the criminal proceedings relating to the dynamite conspiracy. According to one of the witnesses, he was able to identify the accused because the latter got directly between him and an electric light, which was at a distance of some 360 yards. The witness said:—"Anyone standing in the window where I stood would catch an object coming between them and the electric light very distinctly," so that not only in America, but in more thinly populated districts, the question of more light should have some effect upon decrease of crime. We all remember Mr. Preece's remark to the effect that an increase in electric lighting would lead to a decrease of policemen, and the more we consider the subject the more this seems to be the case.

GLOW LAMPS FILLED WITH HYDROGEN.—The *Elektrotech. Zeitschrift* of April, 1886, says that lately the Bros. Siemens have been manufacturing glow lamps, whose glasses are filled with hydrogen. It had been remarked before that glow lamps in which the inner glass wall had been rendered brown could be cleaned by filling them with hydrogen and then exposing both the carbon filament and glass to a high temperature. These lamps are said never to become brown at all, and to last longer. They can be used with higher electromotive forces, and consequently under conditions considerably more favourable to economy, without diminishing their wear. It is thought that many evils which are found in the vacuous glow lamps now in use will disappear when the carbon filament is in an atmosphere of a gas exerting considerable pressure, but not acting chemically upon it.

FRENCH PHYSICAL SOCIETY.—At the Exhibition of the French Physical Society, which was opened on the 27th and 28th of April, the telephonic apparatus of M. Mercadier was especially interesting. In one telephone the membrane was strewn with iron filings, which placed themselves along the force lines. The working of this instrument proves that in a telephone it is immaterial what is the form, the rigidity, and the continuity of the magnetic system whose movements produce and reproduce the sounds. A telephone with an aluminium membrane proves that telephonic effects may be obtained by electro-magnetic induction of currents, as well as by magnetism in the membrane, though, of course, iron gives results of greatest intensity. Another telephone with a copper membrane was strewn with iron filings. Here there is the superposition of the magnetic effects in the iron, and the inductive ones in both the copper and iron.

FRENCH TELEGRAPHS.—We are now able to give a little further information upon the telegraphic reductions just made

Digitized by Google

in France. M. Granet, the Minister of Posts and Telegraphs, has decided on a reduction of 50 per cent. on the existing tariff for telegraphic news addressed to the newspapers. This reduction will come into force on 1st June. Special letters, for the purpose of identification, will be issued by the Minister of Posts and Telegraphs to the correspondents of those papers which desire to benefit by the reduced rates. There will be no limit as to the number of words sent under the new tariff. M. Granet intends to do away with the obligation at present imposed upon senders of telegrams of giving their signature and address at the foot of the telegram. But as this formality was imposed by the law of the 8th May, 1867, it can only be repealed by the Chamber, and a measure to this effect will be laid before the French Parliament.

Electric Light in France.—The value of the electric light is gradually making itself felt, and according to our contemporary *L'Electricien* the small town of Bourganeuf, of four thousand inhabitants, has adopted the electric light. The initiator of the scheme was M. Ernest Lamy, who adopted the simple plan of endeavouring to introduce the light into the small towns which are not yet lighted by gas, and which have water power used during the day in various industries and during the night as the motor power for driving the dynamos. About 300 lamps will be installed, of which little more than 100 will be generally in actual use. The motor power is obtained from an old water wheel, driving a Thury dynamo with 6 poles, compound wound, making 450 revolutions per minute, giving normally 111 volts at the terminals of 180 amperes, but capable of producing 225 amperes. The distribution is by means of aerial insulated wires. The lamps are by Messrs. Woodhouse and Rawson.

Plating Without Electricity.—A curious phenomenon has been observed by M. Blondlot, and communicated to the French Academy of Sciences. A disc of platinum and a disc of copper, 0·03 metre in diameter, were fixed vertically in front of each other by help of two platinum stands. The discs were three or four millimetres apart, and both were placed inside a bell jar of porcelain, open below. The apparatus was then heated red hot for three hours by means of a gas furnace; and although there was no electric current, it was found that the face of the platinum disc was blackened with a deposit containing copper and platinum. In short, the copper had crossed from the copper plate to the platinum one. M. Blondlot, by repeating the experiment in different gas, found that the nitrogen of the air was the agent in this transport of matter. The nitrogen combines with the copper, and lodges on the platinum, either incorporating itself with the latter or decomposing in contact with it under the influence of its high temperature.

A Chemical Process for Making Carbon Filaments for Incandescent Lamps.—This process is described by Mr. A. Smith in *Dingler's Polytechnisches Journal*. Hydrogen chloride is passed through furfuraldehyde, or fucusaldehyde, and a black liquid is obtained that is placed between two glass plates. From this liquid a thin layer of carbon separates after eight or ten hours, and the thickness of the layer is regulated by inserting wires between the plates. This layer is removed, cut into strips, and twisted, and heated to 100 degrees C. Afterward, these filaments are heated in closed crucibles, through which a current of marsh gas is passed. Their electric resistance can be changed by the addition of 2½ per cent. of lamp black to the furfuraldehyde. For the preparation of carbon rods for arc lamps finely powdered carbon is mixed with from 60 to 70 per cent. of furfuraldehyde, and the mixture subjected to powerful pressure in suitable moulds. The rods thus formed are exposed to the action of gaseous hydrogen chloride, after which they are highly heated in closed crucibles covered with powdered carbon.

The B.A. Meeting at Birmingham.—The Gülcher Electric Light Company have secured the contract for lighting Bingley Hall during the Association Meeting to be held in September. The installation is to be carried out under Mr. Henry Lea, the consulting engineer, and will be of a very complete nature. The interior of the hall is to be lighted with 28 3,000 candle-power Gülcher arc lamps. Old Birmingham, which it is anticipated will form a very attractive part of the Exhibition, will be lighted with 160 incandescent lamps, suspended either by flexible pendants or upon suitable fittings. The current for driving the 28 lamps and 160 incandescent lamps will be generated by four compound wound Gülcher dynamo machines of their latest and most improved type. Three machines will be in actual work, the other being used as a spare one in case of accident. The motive power for driving the installation is to be provided by Messrs. Tangyes', Birmingham. The engine will be of the double cylinder horizontal type. The London and North Western Railway Company supply the boiler power from one of their locomotive boilers, which they have lent for the occasion.

Electrical Quacks.—We are glad to see that in France some attempt is being made to punish the men who attempt to make money out of the ignorance of the general community. We are sorry there is no institution in England to take up the prosecution of many of the quacks who are continually advertising electric and magnetic appliances which are utterly worthless to effect the purpose they are said to effect, and we should be glad to chronicle similar prosecutions and similar results to that of Lyons. A man named Tournus was summoned before the Lyons Correctional Tribunal on the charge of unlawful practice of medicine. He professed to be able to cure baldness by means of a certain magnetic water, to which he imparted the mysterious fluid in presence of his patients. The defendant produced a testimonial from a person who declared the results of the lotion were magical, and enclosed as a mark of gratitude a cheque for £20. He had also sold extensively what he called electro-vegetable pomade. Tournus, who in answer to a question of the judge said he had tried his magnetic restorer upon himself, is notwithstanding perfectly bald. The tribunal sentenced him to pay a fine of 15fr. and the costs.

Tasmania.—Mr. W. L. Dobson, Chief Justice of Tasmania, in the course of a paper, which he read recently before the Royal Colonial Institute, on Tasmania, said there is a network of telegraphic wires all over the inhabited portions of the colony, whilst a duplicated submarine cable has been laid across Bass's Straits from Tasmania to Victoria; and thus the colony is placed in connection with the telegraph system of the rest of the world. What are we doing here to-night will probably be telegraphed to Australia, and will, with the other news of the day, appear at breakfast-time to-morrow morning in the daily press of Tasmania. The new system of telegraph communication now organising in Canada may prove to be beneficial to Australia and the East. It appears the Canadian Pacific Railway Company is organising a system of trans-continental telegraphic communication stretching from the Atlantic to the Pacific, and having connections with all the principal American lines and Atlantic cables. When this new telegraphic system is completed it will be one of, if not the, most thorough and complete systems of telegraphy in the world. At present the company are working three

Digitized by Google

wires between Montreal and Winnipeg, and a fourth wire is now being laid. It is expected that the entire system will be opened for commercial purposes early this summer.

ELECTRIC LIGHTING FOR TORPEDO BOATS.—The Admiralty has just placed with Messrs. Willans and Robinson, of Thames Ditton, an order for engines and dynamos for thirteen sea-going torpedoboats. The engines are of the well-known Willans three-tandem type, and they are coupled direct to dynamos by Messrs. R. E. Crompton and Co., giving a current of 50 amperes and 80 volts. The revolutions are 650 per minute. Under a recent patent of Mr. Willans the crank chamber of the engine is made in one casting, with a frame which supports the magnets, and which also carries the bearing at the outside end of the armature spindle. The ordinary frame of the dynamo is thus dispensed with, and there is a still further saving in weight through substituting the single casting described for the independent crank chamber and bed plate usually fitted. The same plan has recently been carried out in some large engines of the central valve type, made by the same makers for H.M.S. "Rodney" with complete success. In that case the dynamos are by Messrs. Siemens. During the last twelve months Messrs. Willans and Robinson have received orders for no less than 37 engines for lighting English torpedo boats, besides some for foreign governments. In the same period they have had orders for 24 larger engines, mostly indicating about 35 indicated horse-power (with comparatively low pressures) for incandescent lighting in large vessels of the English navy, and for about as many engines of medium size for search lights.

ELECTROMOTIVE FORCE OF ZINC-COPPER AND LEAD-PLATINUM COUPLES.—From a large number of determinations of the electromotive force of the currents yielded by zinc-copper and lead-platinum couples in various simple saline solutions, B. C. Damien—*Ann. Chim. Phys.*—finds that the electromotive force, as a rule, decreases with the time the couple is immersed. In the case, however, of the zinc-copper couple in solutions of the chlorides, the electromotive force at first slowly increases. The electromotive force of the current yielded by a zinc-copper couple in a solution of magnesium sulphate is very constant, scarcely varying 0·017 volt during twelve months, and is not appreciably affected by changes either of the strength of the solution or of temperature. By introducing an exterior resistance of 20,000 ohms, the current becomes practically invariable, even when the couple is kept in circuit. The author proposes to employ this couple for the generation of currents of standard strength. The zinc-copper couple yields currents whose electromotive force is almost identical for members of any class of salts containing a given acid, but varies greatly with a change of acid. Amalgamation of the zinc slightly increases the electromotive force at first, but it decreases more rapidly than is the case when unamalgamated zinc is employed. The current obtained from a platinum and amalgamated zinc couple in dilute sulphuric acid has its maximum electromotive force when its solution contains 30 per cent. of acid.

GAS COMPANIES IN SPAIN.—We recently referred to the decision of gas consumers of Madrid to dispense with that mode of lighting, and to replace it by electric light; but Madrid does not appear to be the only town in Spain in which dissatisfaction with the gas companies is beginning to manifest itself in active opposition. According to advices from Cadiz the dispute over the lighting of the town has recently become so acute as to threaten a breach of the peace. Hitherto the the town has been supplied with gas by a company established in Paris (E. Lebon and Co.). On the termination of the contract a local company was formed (the Sociedad Co-operative Gaditana), and, with the approval of the present Ayuntamiento, immediately commenced operations by erecting works and laying pipes, &c., though hampered by threats of litigation by the French company, which appears to have been promised a renewal of the concession by the former Ayuntamiento. The matter has been brought to a crisis by a summary order from the Government for the suspension of the operations of the new company, much to the disgust, it is said, of the general public. Meetings have been held, at which it was decided to discontinue the use of gas, and return the meters to the Lebon company; to close the business establishments in the evening, pending some other arrangement; to organise a general support to the local company; to petition the Queen and the Government against the prohibitive order referred to; and in the meanwhile to use petroleum or some other light both in private houses and in business establishments.

DENVER.—The City of Denver, says the *Electrical World*, stands almost alone in this country in the matter of street lighting. Both arc and incandescent lamps are used in a combined system under one management. Another peculiarity consists in the fact that the Brush Company is running Edison lights. For arc lighting the Brush system is used. There are six towers, on each of which are six 3,000 candle-power arcs, and on another tower are four 3,000 candle-power lights. Besides these are seven masts, each of which carries a 3,000 candle-power light. This alone would give a good light, but in addition each of the 500 lamp posts that once held a dim, flickering little jet of gas is adorned with a 20 candle-power Edison lamp. The result is eminently brilliant and pleasing. The cost of the service is anything but large. The bid of the gas company was $35 a year per street lamp, whereas the incandescent lamps are furnished at $28. The arc lights cost the city $150 for each mast; $960 for the tower with four lights; and $1,296 for a six-light tower. Supplementary to the city lighting, the local company has 300 private lights in use, at $13 a month for 10 o'clock lights, $15 for 12 o'clock, and $20 for all night. The station is run by three engines—one 250 horse-power made by W. Wright, of Newburgh, New York; a Corliss of 166 horse-power, made by Fraser and Chalmers, of Chicago; and a 50 horse-power from Hendey and Meyer, of Denver. The capital of the company is $200,000. Mr. W. B. Rundle, a well-known electrician, is the superintendent, and Mr. R. H. Sterling is the electrician. The company is evidently doing a good business, and there is a project of forming two companies, with two plants, one to attend to the arc lighting and the other to handle the incandescent lighting.

THE AQUARIUM.—The Royal Aquarium, Westminster, has now been lighted for four months by the Gülcher Company. The installation consists of 23 Gülcher arc lamps distributed as follows:—Seven 3,000 candle-power arc lamps of the type used for indoor work, and suspended by the company's improved raising and lowering apparatus are used, for the interior lighting of the main building; six 2,000 candle-power arc lamps of a similar type are used for lighting the new dining hall; three 2,000 candle-power arc lamps light Messrs. Beckwith's diving and swimming departments; and seven 2,000 candle-power arc lamps, fitted with weather protectors and iron reflectors, are used for the outside lighting, three being placed at the front of the building and four along the side. Messrs. Bertram and Roberts's dining rooms are lighted by seventeen 20 candle-power incandescent lamps, eight being placed over the dining tables, three in the large private dining room, and two in the small room, the balance being used for lighting the manager's office, &c. The

Digitized by Google

current for working the installation is obtained from three No. 4 Gülcher dynamo machines, placed in an engine house by the side of the hall, to which persons desirous of obtaining information of the installation can have access. The current from the machine is led to switches, so that any part of the installation can be lighted as desired. Suitable measuring instruments are also connected by means of switches to the machines, so that at any moment the attendant in charge can read either the amount of current flowing through any circuit or the E.M.F. at the terminals of either of the three dynamos. The motive power for driving the installation is obtained from one of Messrs. Roby's 16 horse-power engines, which has given great satisfaction, and runs with great regularity of speed.

Cost of the Electric Light.—For the last two or three years, week in and week out, scores of articles have been written discussing the cost of the electric light. In ninety-nine per cent. of these cases the basis for the calculations has always been an assumed quantity. It comes to be a different thing, however, when tenders are asked for supplying the light wherever these tenders may be sought for. We are then able to obtain some definite idea as to the cost of such light. Below we give the tenders for lighting Galesburg, Illinois, the city having asked the cost of 65, 85, and 100 light plants respectively :—

Brooklyn Electric Light Company—	
65 single arc lamp plant	$14,530.00
65 double carbon lamp plant	15,180.00
85 single arc lamp plant	15,080.00
85 double carbon lamp plant	16,080.00
100 single arc lamp plant	16,470.00
100 double carbon lamp plant	17,470.00
Thomson-Houston Electric Light Company—	
65 single arc lamp plant	$15,463.75
65 double service lamp plant	16,000.00
85 single arc lamp plant	16,899.00
85 double service lamp plant	17,600.00
100 single arc lamp plant	19,046.00
100 double service lamp plant	19,871.00
Brush Electric Light Company—	
65 single arc lamp plant	$11,099.75
65 double lamp plant	11,489.75
85 single arc lamp plant	14,514.60
85 double arc lamp plant	15,024.60
100 single arc lamp plant	17,076.00
100 double arc lamp plant	17,676.00
Fort Wayne Jenney Electric Light Company—	
65 light plant	$13,445.00
85 light plant	15,725.00
100 light plant	17,485.00
Sperry Electric Light, Motor, and Car Brake Company—	
60 arc light system	$7,000.00
85 arc light system	8,000.00

All the tenders were referred to the Street Lighting Committee.

Contact Action.—The tendency of all scientific investigation at the present time is to show the close connection of electrical with molecular phenomena, and anything throwing light upon the latter will probably ultimately assist in throwing light upon the former. Mr. D. Mendeléeff, according to the *Journal* of the Chemical Society, says : "It is a generally received opinion that not only the molecules as a whole, but each of the constituent atoms, are in motion, the movement of the latter being conditioned by the limits of the molecule. If the conception be reasonable, then in every state of aggregation there are presumably motions of two kinds, the one internal, the other superficial. The contact of two molecules, as also conditions of temperature, pressure, and electric potential, influence each kind of motion; thus the phenomenon of catalytic or contact action gradually passes into that of dissociation or of decomposition. Herein the decomposition of hydrogen peroxide is analagous to that of many detonating solids, in which a disturbance of atom-equilibrium at the superficies of the molecule causes its complete disruption. Now supposing two substances, A and B, are in superficial contact with one another, under such conditions that not only the superficial movement of the constituent parts, but also of the molecule as a whole is disturbed, then three distinct cases are possible :—Firstly : The atoms change their kind of motion without returning to their former state of equilibrium ; no chemical change ensues, but merely a physical phenomenon, such as alteration of electric potential, condensation of gases, whether by cold surface or by porous substances. Secondly : The internal movement of the molecules is altered, so that molecules of a different kind are formed by combination, replacement, or decomposition. These changes are accompanied by an alteration of the energy of the system, but although the total heat effect observed is the algebraical sum of the energy changes, conditioned by the several changes of motion, yet thus far it is not possible to assign to each particular change its peculiar heat effect. As an example of chemical changes induced by the mere superficial contact of the molecule as a whole, the author quotes the well-known experiments of Spring on the combination of metals with sulphur by mere pressure. Thirdly : The motion of the atoms within the molecule taken by itself can be of such a kind as to produce a chemical change of formation of a molecule of a different kind, such as the so-called isomeric transformation. Or, again, the superficial contact of B with A, a mixture of heterogeneous molecules may cause either a decomposition or a combination between them, as exemplified in the experiments of the Hautefeuille and Lemoine, which demonstrate that the presence of porous substances can induce the combination of hydrogen with iodine, and conversely the decomposition of hydriodic acid, both reactions attaining a limit. Of a similar nature is the combination of hydrogen with oxygen, induced by contact with finely divided platinum, and also the recent experiments of Konovaloff on the decomposition of haloïd derivatives of pentane by contact with materials in a state of fine division. These phenomena are generally classified under the title of catalytic or contact actions. Such can only be explained on the hypothesis that a stable substance B is in such a condition that moderate perturbation of the constituent atoms at its superficies produces no disturbance in the atom equilibrium of the molecule ; whilst in the case of a changeable substance A, the equilibrium of atoms within the molecule is of such a kind that a comparatively unimportant change of motion at the superficies can cause the atoms to assume a different form—that is to say, can cause the production of a different kind of matter. If this be a correct representation of these contact phenomena, then the induced reaction should either be accompanied by a slight heat change, or if accompanied by a considerable heat change, then the reaction should be capable of proceeding by itself in the direction of the heat evolution. An example of the former case is the reaction between hydrogen and iodine; of the latter is the system of hydrogen with oxygen in contact with platinum, which causes a lowering of the reaction-temperature. In conclusion, it is remarked that it is desirable to find a method of research, not only to explain the connection of contact action with other kinds of chemical change, but also even of the mechanism of the chemical change itself."

PRACTICAL ELECTRICITY FOR AMATEURS.—II.*

Electric Bells and Indicators.

Bells are occasionally required to ring continuously when once started. One arrangement is shown by Fig. 6. The action is as follows: upon the push being pressed, the current enters at C, passes through the coils and contact to L. This causes the armature to be attracted, which releases the lever to which the cord is attached, so that it falls into the position shown by the dotted lines. The current now passes from C through the coils into the upper contact post, thence to the lever and lower contact post, which is connected to Z. The line is thus cut out and the bell continues ringing until the lever is raised by pulling the cord. As this arrangement, however, is rather uncertain in its action, unless very carefully

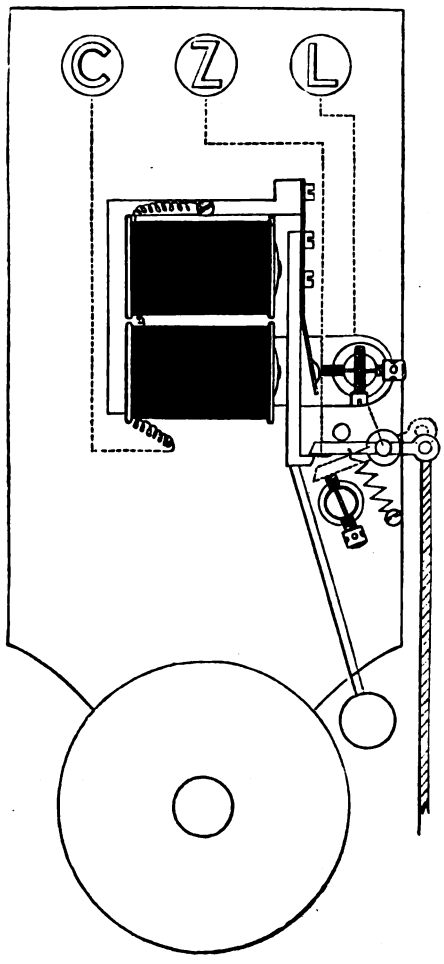

Fig. 6.

made, the arrangement shown by Fig. 7 is much to be preferred. In this case, when the push is pressed the current enters at C, thence through the coils of relay direct to line. This attracts the relay armature, causing the lever to fall against the upper-contact post The current then flows through the bell coils and lower contact, thence to upper contact and lever to Z. The bell continues ringing until pulling the cord raises the lever.

Pushes.—The variety of designs in pushes is numberless, but the principle is the same in all, viz., by the contact of a spring with another fixed or spring connection, as shown by Fig. 8.

In bed rooms a pear shaped push, depending from a silk cord, is often used, as shown by Fig. 9.

As, however, this form is liable to injury by violent use, many persons pulling at the cord as if using an ordinary bell, it is better to use a contact box, shown by Fig. 10, to which the ordinary bell ropes can be attached.

For front doors it is preferable to use pulls with the contacts arranged as shown by Fig. 11.

* For Article I. see *The Electrician* for May 14, 1886.

The use of ordinary pushes is open to several objections; the damp gets into them, causing rapid corrosion and swelling of the woodwork, and the button to stick in. Many persons do not understand the use of them, and lads of an experimental turn cannot resist ringing as they pass by.

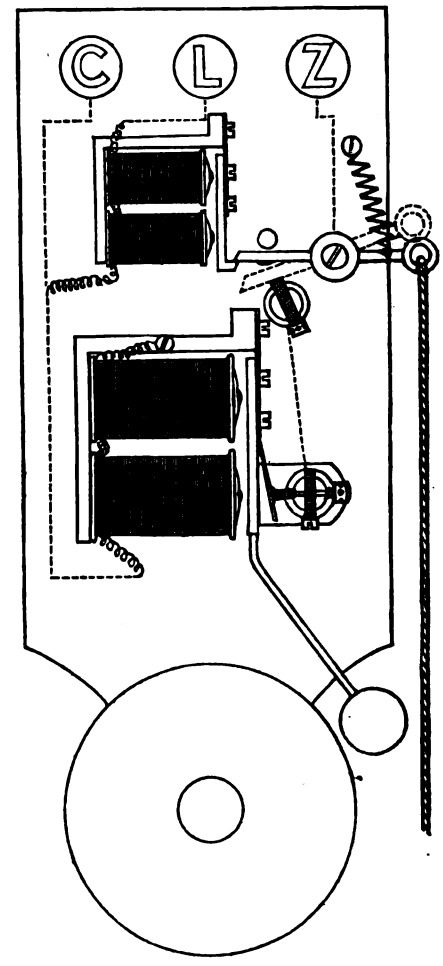

Fig. 7.

For insertion in floors under dining tables, &c., the form shown by Fig. 12 is very convenient; the covering in centre is made of rubber or leather.

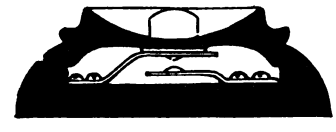

Fig. 8.

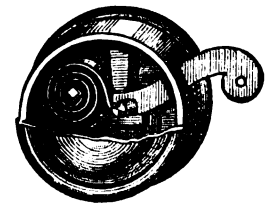

Fig. 10.

Fig. 9.

Sounder Pushes.—One of the usual complaints against electric bells is that no means exist of knowing whether the bell has rung after the push button has been pressed. Several attempts have been made to overcome this defect, but none of sufficient simplicity and cheapness to warrant their general introduction. The Mackenzie indicators recently introduced answer the purpose admirably. Their application to ordinary pushes is shown by 14 and 15.

Digitized by Google

The mode of action can be readily seen by referring to Fig. 13. A is a soft iron core, fixed to an iron base, D, and surrounded by a bobbin of wire, which forms part of a circuit upon which the appliance has to be used. An iron box, C, is put over this electro-magnet, having the lid E close to the end of the core. Upon the current flowing round the bobbin the wire A and the lid E, being the respective poles of a continuous magnet, become magnetised with opposite polarities, and emit a sound which can be increased to any given extent, and which continues to be given out so long as the current is passing. This is the well-known "Page effect" made use of practically.

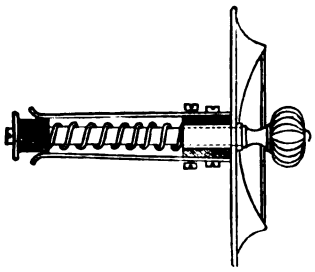

Fig. 11.

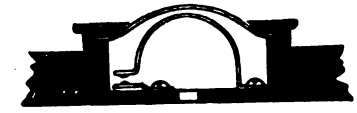

Fig. 12.

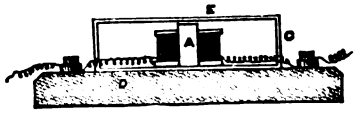

Fig. 13.

The action being solely molecular, no moving parts are needed, and therefore there is nothing to get out of repair; and, being an audible instead of a visual indicator, its use is not restricted to any place where light is required.

The apparatus can be adapted to any place where electric bells, &c., are used, and can also be made to take the place of a bell itself if required.

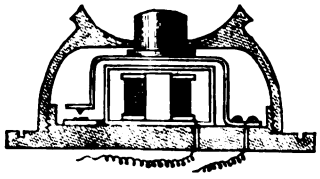

Fig. 14.

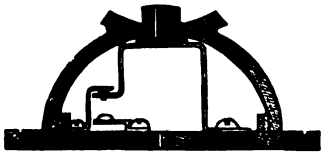

Fig. 16.

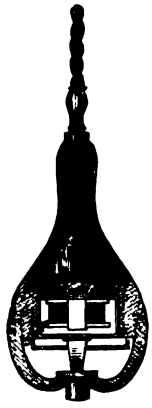

Fig. 15.

Key Pushes.—On lines where electric bell signals are both sent and received the form of push shown at Fig. 16 is used. When the push is at rest the spring is pressing against the contact *a*, or in connection with the bell *b*, but upon being pressed the spring comes against the contact *c*, which is connected with the carbon pole of battery, thus sending a current to ring the bell placed at the other end of the line.

ON THE WEBERIAN THEORY OF DIAMAGNETISM, AND On the Rotation of the Plane of Polarisation of Light by Magnetic and Diamagnetic Substances.

BY MISS J. M. CHAMBERS, B.SC.

The idea of supposing currents in molecules similar to those in conductors is due to Ampère. He, however, limited his ideas on the subject, as far as we know, to those permanent currents which are still called Amperian, and which, if his idea is correct, are the sole cause of the phenomenon known as magnetism. At that time the law of Lenz was not known, and I do not know whether electro-magnetic induction had ever even been observed. In Weber's theory of diamagnetism the idea of molecular currents is extended, and he deals with induced currents in them as well as permanent ones, these induced currents being produced in the same way and in accordance with the same laws as those in ordinary conductors. Faraday had a great notion of a molecular action of the medium in opposition to the theories then held of action at a distance. Maxwell's theory of light presupposes a "series of oppositely directed magnetisations and electromotive forces." In my conception of the idea of his theory (*Phil. Mag.*, Feb., 1886) I make the propagation of light depend on an action precisely like that which might be supposed to take place in a row of ordinary conductors. The object of the present paper is to extend this idea even further, and to bring into co-ordination the ideas of Ampère, of Weber, and of Maxwell's theory of light—that is, to take into account the interaction of the molecular currents presupposed in the three theories. I thus obtain a complete *explanation* of the rotation of the plane of polarisation of light in opposite directions by the two classes of substances. The experimental facts known are in complete accordance with these combined theories. Further, there is a crucial experiment, which has never yet been performed, by which the theory may be tested. If the result of this experiment is such as I expect, the probable nature of the action of the medium in electrical phenomena will be rendered clear. Of course we must consider the æther as the medium when no ponderable matter is present.

This combined theory makes the rotation of the plane of polarisation of light in opposite direction by the two classes of substances an argument in favour of Weber's theory of diamagnetism.

Ampère's theory may be extended somewhat. He supposes the molecules are circuits with electricity travelling round them in one particular plane. It is possible that currents may also be travelling round them in a perpendicular plane, but that the currents in one plane are stronger than those in the perpendicular one.

The effect of the molecular current, which is produced by the magnetic field in accordance with Lenz's law, and which by the Weberian theory produces diamagnetism, may be dependent on three things.

I. The strength of the original Amperian current in the molecules.

II. The resistance of the molecules.

III. The coefficient of mutual induction between each molecule and the field, which, if the field is uniform, is the effective area of the molecular circuit. In connection with this there is also the coefficient of self-induction of the molecular circuit.

I will call the strongest permanent current in the molecule the amperian current and the other permanent ones magnetic currents, as a distinction from diamagnetic currents, which latter are the ones produced in accordance with Lenz's law and Weber's theory.

Now, the Amperian and magnetic currents flow, we suppose, constantly for ever. We can hardly suppose there is a source of E.M.F. in a molecule, which would be equivalent to saying that matter could produce energy. Hence we must suppose that there is no resistance in a molecule, and, if this is the case for the permanent currents in it, we may suppose the same to be the case for all currents in it. Thus the effect of the introduction into a magnetic field on any substance, we will suppose, depends only on I. and III.

The current produced in the molecule in accordance with Lenz's law, that is, the diamagnectic current, depends on the effective area of the circuit. The effect of the self-induction of the current on itself will be that no lines of force due to the induction of the field will pass through the circuit. (See C. Maxwell, Vol. II., Art. 654.) The Lenz effect in ordinary conductors is transitory; but in a circuit of infinite conductivity it lasts as long as the force lines producing it fall on the circuit, and ceases only when they are removed. Since no force lines due to the induced current pass through the circuit in this case, it might be supposed that the action was confined to the external molecules; but there are the external force lines. Now, we do not suppose that the molecules fit into one another like bricks, but we rather suppose that there may be interstices between them. The external force lines of the diamagnetic currents will be of the same sign as those of field,

Digitized by Google

and we may suppose that some of them pass through the interstices and strengthen the field for the molecules behind. In fact, the lines of induction pass outside not inside the molecular circuits on this theory. In the case of a diamagnetic, the interstices between the circuits will probably be as large as possible, because the smallest circuits in the molecules will tend to place themselves perpendicular to force lines. The field, therefore, for molecules behind the first row is that due to (I.) the Amperian currents in the molecules next them, the external lines of which are of course contrary to those of field, plus that due to (II.) the force lines of field which pass through the interstices, plus that due to (III.) the external lines of the Weberian or diamagnetic currents which pass through the same interstices.

Before proceeding further I will briefly state the theory which is, I believe, now most in vogue—that is, that whether a body acts as a paramagnetic or a diamagnetic, depends on whether it is more or less magnetic than the medium in which it is. The ordinary theory might be explained by supposing that all molecules had Amperian currents in them, but that these varied in strength, and that no Lenzian effects occurred in them at all.

The reason of a piece of soft iron setting lengthwise along the lines of force is given in "Deschanel," Art. 692. He ignores the medium altogether; but the argument will still be valid if we suppose the iron more magnetisable than it. In a similar manner, if the magnetism of the medium is stronger than that of the bar, we can show that the bar will place itself perpendicular to force lines.

Thus, suppose 1, 2, 3 three molecules of the bar rigidly connected together, and 4 and 5 two molecules of the medium. Since the magnetism of the molecules of the medium is the strongest, N_2 will be attracted by S_5 more than by S_1, and S_2

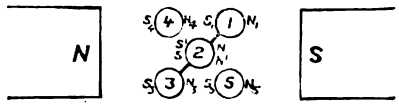

Fig. 1.

more by N_4 than N_5. Thus N_2 will tend towards N′ and S towards S′, which will cause the rod to turn more to the equatorial position, when the field is uniform, or nearly so. (Another theory by which a diamagnetic would also set with its long axis along lines of force in a uniform field is given by Deschanel. It ignores the medium and supposes the poles of a diamagnetic molecule in a reversed position to those of a magnetic one.)

I will now proceed to develop the Weberian theory.

When a substance is introduced into a magnetic field the molecules will tend to turn so as to place the planes in which are their Amperian currents perpendicular to the lines of force. The field will also induce currents in the molecules in accordance with Lenz's law. Owing to the tendency of the molecules to place the planes of Amperian currents perpendicular to lines of force, the diamagnetic currents will be formed in those planes in the first instance. Now, if the Amperian current is so strong that it outbalances the induced (or Weberian) current, the substance is magnetic. If, on the other hand, the Weberian current is greater than the Amperian, the circuit will tend to turn through a right angle. In doing this a Weberian current will be induced in a perpendicular direction, or at least in another direction. The amount of this current depends on the effective area of the circuit—that is, on the number of lines of field which are enclosed by circuit. In general, a molecule will tend to place itself with regard to force lines so that the greatest Amperian or magnetic current is perpendicular to them and the least Weberian or diamagnetic one, and the actual position taken up by it will depend on the resultant of the two actions. Of course there may be molecules with no Amperian currents, and in this case that plane of the molecule will place itself perpendicular to force lines in which its circuit has the least area. A penny between the poles of a magnet tends to place its plane along the lines of force simply because its area is least perpendicular to that plane. The Amperian current is independent of this area. When there are magnetic currents, which are insufficient to outbalance the induced ones, the matter will become more complicated. The molecule may have in any case no current at all perpendicular to force lines, an Amperian one or a Weberian one. We may have in a diamagnetic substance two poles joined by force lines as in a magnetic one, but in reversed positions. At the same time the poles due to the Amperian currents might have their joining line perpendicular to or in an oblique direction to force lines. The Weberian current depends on the effective area, but it also depends on the strength of the field. Hence the Weberian current will increase as the strength of the field increases. Hence it is possible to explain how a magnetic substance might become diamagnetic in a strongly magnetisable medium. The lines of force are drawn in by the medium, and the substance is consequently in a stronger field. Some recent experiments of Dr. Lodge show that possibly a substance which sets axially in a weak field may set equatorially in a strong one, the medium remaining the same (see *Nature*, March 25th). In such a case, of course, the medium might or might not remain magnetic. On this theory it does not seem impossible that the most magnetic substance might become diamagnetic if the field were sufficiently strong.

The reason of the setting of a magnetic substance, with stronger Amperian currents than those of medium, with its long axis along lines of force is explained in this theory as in the ordinary theory; so also the equatorial setting when the Amperian currents of the medium are the strongest. When the Weberian currents outbalance the Amperian the matter becomes more complicated. Probably, if both medium and bar are diamagnetic, and the bar the more strongly so, the setting would be again axial in a uniform or nearly uniform field. Of course there are several intermediate cases. Thus setting becomes no certain sign, whether the bar is magnetic or diamagnetic. I should think the rotation of the plane of polarisation of light the truer test, as will be seen from what follows.

The experiment of Beetz does not affect the theory, for of course the magnetic effect for a magnetic substance will be greatest when the planes of all the Amperian circuits are parallel.

I now come to the rotation of the plane of polarisation of light by magnetic and diamagnetic media, and this in conjunction with "A Simple Manner of Explaining C. Maxwell's Electro-magnetic Theory of Light" (see *Phil. Mag.*, Feb., or *Electrician*, Feb. 5, 1886) affords a plea in favour of Weber's theory.

Suppose we have a molecular circuit with an Amperian current travelling round it in the direction of the curved arrows. Suppose at the same time an E.M.F. to act which causes a straight current from A to B. Now, the current

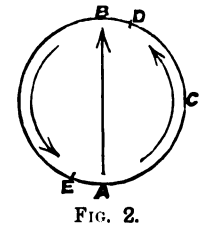

Fig. 2.

along A B will be attracted towards C all the time it passes upwards, in accordance with the general laws of the action of one current on another, and instead of reaching B we may suppose it arrives at some point, D. If now its direction is reversed, it will be attracted towards the opposite side, so that by one bob up and down it will reach E. The effect is that the general direction of the current is twisted through a certain angle. The amount of twist will depend on the strengths of the currents. This twist would be in the opposite direction if the circular current were in the opposite direction. Thus, the direction of rotation of the plane of polarisation of light depends upon whether the magnetic or the diamagnetic current is the strongest. This applies equally whether the direction of the E.M.F. or the direction of the magnetic force lines is the direction of the vibration which constitutes light, since the magnetic force lines always remain perpendicular to the current.

Digitized by Google

I here suppose the same attraction to take place between the currents as would take place between the conductors carrying them if they were in separate conductors. I do not know whether this is a perfectly legitimate supposition, though I know of no experiment which either proves or disproves it. (The electric arc is drawn aside by a magnet; but, perhaps, here it is the particles of carbon bearing the electricity and moving with great velocity which are drawn aside.)

Thus the rotation of the plane of polarisation of light becomes the true test whether a substance is magnetic or diamagnetic, and the discrepancies experimentally found between the rotation of the plane of polarisation and the setting of a substance in a magnetic field are explained.

This theory also accounts for the double amount of rotation when the ray is reflected back along the same path. In the case of rotation in substances when there is no magnetic field the rotation is due to the difference of velocity with which the two circularly polarised rays, into which the plane polarised ray can be resolved, travel, as is plainly shown by Fresnel's experiment of the compound prism (*Annales de Chimie et de Physique*, 2nd série, Tome XXVIII., p. 147; *Œuvres Complètes*, Tome I., p. 731). This experiment is the following:—

A ray of plane polarised light, L R, falls normally on the first prism, and the two circularly polarised rays keep together in this prism. The prisms are of alternately positive and negative quartz, with the axis of crystal along the direction

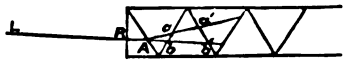

Fig. 3.

in which the ray passes. The second prism will act as if of denser medium for one circular ray, and of rarer for the other circular ray. Hence in the second prism the two rays become separated. In the third prism they are bent farther apart, because the action is reversed, and so on. It can be shown by the usual tests that the two rays are circularly polarised when they emerge from the compound prism.

The two circularly polarised rays are bent just as ordinary light is bent by an ordinary prism, and the bending in the former case, like that in the latter, must be due to change of velocity of propagation. When the rotation is due to molecular structure and the ray is reflected back, the rotation is destroyed, since, on the return passage, the direction of circular rotation taken with respect to the forward movement is reversed.

In the case of the quartz the vibration period and angular velocity in the two rays are the same, but their velocity of propagation is different in each prism. But there is another way in which the plane of polarisation might be rotated. The vibration period and velocity of propagation for both rays might be the same, but the angular velocity might be different in the two rays, and this is somewhat what I suppose to be the case in the magnetic field. The rotation in due to a totally different cause from that in the quartz. In the case of the rotation in a magnetic field a compound prism would *not* separate the two circularly polarised rays.

I have been told that the movement of a particle in a circularly polarised ray of light is very well represented by a corkscrew which we cause to rotate about the axis of the helix. If we mark a small spot on the corkscrew, this spot will simply appear to bob up and down when the line of sight is perpendicular to the length of helix; but will describe a circle when viewed along the length of helix. This supposes the period of the angular velocity to be the same as that of the transverse vibration. In this case the wave-motion along the direction of propagation is represented by Fig. 4. But it is quite possible to suppose the angular period different from the transverse period. In this case the wave-motion along the direction of propagation would be represented by such a figure as Fig. 5. There would, in fact, be a double period in such a case. I mention this to show that there are two ways in which retardation of one circular component on the other can take place.

It would be a curious modification of Fresnel's experiment to make the compound prism, instead of quartz of alternately positive and negative rotations, of alternately magnetic and diamagnetic media, and see whether the two circularly polarised rays could be separated. According to this theory they could *not* be so. The separation would not take place, because the retardation of one ray over the other is in the angular velocity, not in the velocity of propagation.

Fig. 4.

At present there are two points which go strongly to confirm the theory.

Fig. 5.

I. The *direction* of the rotation in each case is *correct*.

II. The amount of the rotation is doubled by reflection as the theory requires.

THE BRIGHTON ELECTRIC RAILWAY.

This line (particulars of which have appeared in previous issues of this journal) has been in constant operation over two years, and we now give some particulars as to the result of the working during this period. The line is rather under a mile in length, and includes some heavy gradients on sharp curves, the gauge being 2·9. The speed is limited to eight miles an hour, but a speed of over twenty-five miles has been obtained. The current is transmitted along the rails, which are fastened to wooden sleepers resting on the shingle, no special insulation being used. Each car seats thirty passengers, and the motor can draw another if necessary.

The plant comprises two cars fitted with motors; one 8 horse-power gas engine; one 12 horse-power gas engine; one Siemens D2 series dynamo; one Siemens D2 compound dynamo.

The working expenses for one year are as follows (average for two years):—Electrical machinery—new commutators and brushes, £10. 0s. 6d.; gas engines—refacing slides, &c., £6. 9s. 10½d.; oil and waste (that used for axles included), £10. 1s. 3d.; gas (including that used to light premises, price 3s. 3d. per 1,000 cubic feet), £114. 3s. 0½d.; attendant—52 weeks, at 18s., £46. 16s.; total, £187. 10s. 8d. The gross earnings per car mile are 1s. 7¼d.; the gross expenses (all renewals being paid out of revenue) 11⅛d.; car mileage per annum, 23,475; cost of haulage per car mile, 1·92d., barely 2d. (this includes the engine attendant).

Only one car is running, except on bank holidays, &c., on which occasion nearly all the power of the 12-horse engine is used. The repairs to the electrical machinery only amount to 5 per cent. per annum, and to the gas engine only about 2½ per cent. The only repairs to the electrical machinery of the two cars—the work having been nearly equally divided, each car having run about 25,000 miles—have been one new commutator and one spindle bush relined with soft metal; that, therefore, represents the wear and tear for nearly 50,000 miles running. The extra cost of running two cars is very slight, only about two-thirds more gas being required, and the other expenses being scarcely affected.

The above result must certainly be considered very gratifying, both to the proprietor of the line, Mr. Magnus Volk, and also to all those interested in electric locomotion.

Irregular Action of Galvanic Batteries.—Experiments have been made on the cause of irregularities in the action of galvanic batteries by H. V. Hayes and J. Trowbridge—*American Journal of Science*—by means of an apparatus for photographing the deflections of a galvanometer needle. The authors tested a number of batteries, all variations of current being accurately registered. Irregularities were found to be caused by two separate actions, a diminution in the current strength, caused by the pores of the partition becoming filled with the base, and secondly, a diminution of the acid at the positive pole. Both these difficulties are overcome by making a partition of as large surface dimensions as possible, and by using very porous material.

THE PADDINGTON INSTALLATION.

A Supplement will be issued with our next number describing and illustrating the Paddington Installation of the Electric Light.

TELEPHONY AND TELEGRAPHY.

To those who are desirous of widely extending telephonic communication in this country Mr. W. H. PREECE'S discourse at the Society of Telegraph-Engineers last week affords very little material for consolation or hope. It is useful, however, as an explanation of some of the natural difficulties, and also of some of the artificial obstacles, which stand in the way of telephonic enterprise. As to the latter, the general cheering which greeted the lecturer's reference to "a grasping and selfish monopoly" showed pretty plainly that his audience understood the allusion, and endorsed the description. The charge was not pushed home with direct evidence or explicit reference to the offending monopoly, and in "another place" the cheering might have been—partly, at least—ironical. But as Mr. PREECE was scarcely likely to have thus designated the Department in which he himself occupies a high position, the inference is that he had in his mind none other than the UNITED TELEPHONE COMPANY, and evidently his audience so understood him. We should like to have seen the case substantiated with fuller detail, but apparently Mr. PREECE thought by contrasting the telephone in other countries with the telephone in this, and asking them to look on this picture and on that, his hearers would themselves draw the right conclusion as to who was responsible for the daub. We cannot pretend to supply the missing links in the chain of reasoning which led to a conclusion that the Company above referred to is wholly or greatly to blame in this matter; but some facts of common notoriety point in that direction, and we have on many occasions ourselves contended that the conduct and policy, if it has a policy, of the UNITED TELEPHONE management were shortsighted, oppressive, and indefensible. That it has kept in check the natural growth of the telephone there can be little doubt; and that it has done nothing, or next to nothing, in providing long-distance telephony is beyond all dispute.

As regards local telephony, the facts are too well known to need recapitulation. The Company has a monopoly, which it uses as monopol sts are apt to do when commercial considerations alone prevail unchecked by legislative limitations in the interests of the public. Its patents are of limited duration, it is true; but this is a circumstance which operates prejudicially against everybody but the proprietors. In this respect, however, the UNITED is on the same footing as the several other companies outside the Metropolitan area. Yet some of these companies have carried on their operations in a far more satisfactory manner, and in many instances have emulated the Post Office system in the neighbourhood of Newcastle by largely invoking the help of long-distance, or inter-urban telephony. That London and its neighbourhood are not well served is a matter of general complaint; and it is alleged that all attempts at improvement on the part of the POST OFFICE when appealed to by the public have been prevented by the refusal of the monopolists to allow any extraneous connection with their Exchanges. For obvious reasons the Government Department cannot enter into sharp competition with a private company, except at the instance of the public; and, of course, the first condition of such a demand is that every telephonic customer shall enjoy equal privileges, which cannot be granted if the company in possession shuts its system against all new comers. We regard this as a perfectly natural result of the situation, which was anomalous from the very first. Telephony, like Telegraphy, must be under one administration to be efficiently worked; and it unfortunately happens that if this one administration is not giving satisfaction, competition will provide no adequate remedy.

All this is extremely vexatious, no doubt, and it accounts for any strong language that may be used; but it has followed from the stupid outcry made against the Government when it endeavoured to acquire the same effective control over the Telephonic system that it already possessed over the Telegraphs. What it actually obtained was a pecuniary interest, which left it as impotent as ever; so that although the country had bought and paid for a monopoly which a judicial decision has since confirmed against the Telephone, the owners of that instrument are practically masters of its application to the wants of the country, and enjoy a monopoly which is worked solely for the profit of private individuals. In the United States this dilemma has been avoided by the virtual absorption of the one system in the other. Over a vast area of the States there exists a monopoly of the Telegraphs, which, though in private hands, resembles for practical purposes the State monopoly here. To prevent friction between the rival systems, and to enable the telephone to benefit by existing telegraph lines, a working arrangement has been come to which virtually makes the two

Digitized by Google

systems one. In Belgium, too, where long-distance telephony has made considerable progress, the State, which owns the telegraphs, has taken the former under its sole control, leaving the town telephones in the hands of private companies, but under rigid conditions which enable the two to work into each other's hands. The connection between the Exchanges and the trunk lines is complete in the places we have named; but this is not the case in England; and one explanation of the fact, no doubt, is the commercial instinct, to use no harsher term, of the UNITED TELEPHONE COMPANY.

From all we hear of the commercial aspects of long-distance telephony, it does not seem to be a paying business even in countries where telegraphy is much slower than in this, except as a means of feeding local Exchanges. In spite of the singularly artificial—we had almost said artful—means employed in America to raise money for erecting trunk line telephone wires, they do not pay; and the statement that 150 telephone conversations daily are held on wires between Antwerp and Brussels seems to us to indicate that ordinary telegraphic messages must travel rather slowly in Belgium. Be that as it may, however, it obviously will not pay the Telephone Companies in this country to erect long trunk wires for the telephone alone; nor, on the other hand, could the Post Office afford to allow its wires to be used in competition by the Telephone Companies. Even were this difficulty got over there is, as Mr. PREECE explained, the electrical one, which is not to be overcome without crippling the telegraph service for the sake of a subsidiary, and, it must be confessed, comparatively unimportant adjunct. To attach the necessary appliances for making telephony and telegraphy possible on the same or closely contiguous wires would immensely reduce the efficiency of the Telegraphs. And here we come to a fact which perhaps more than any other has conduced to stay the advance of telephony generally in this country. We have a telegraph system which, in point of equipment, comprehensiveness, efficiency, and high speed, is such as no other country in the world can boast of. To all intents and purposes users of the English telegraphs—at all events between large centres of industry and commerce—do daily hold constant conversation by telegraph. The telephone would be as superfluous as it certainly would be invidious and costly. It found us in this condition, and the truth is it could not better the existing means of communication. It has its own peculiar province, no doubt—but a limited one at the best; and although much, very much, remains to be done, and done, too, in a far better way than at present, the universal extension of the telephone is a dream, which cannot be even partially realised until the system falls into the hands of one controlling or State-regulated administration.

CORRESPONDENCE.

THE POLARITY OF TADPOLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the experiment made by Prof. L. Herman in connection with the above subject, which was reported in your issue of April 23rd, the following explanation of the phenomenon has presented itself to my mind. As soon as the current was made, the tadpoles all turned towards the anode and soon became motionless. This seems to me to show that what took place was exactly similar to the application of the positive pad to the human subject, as described by Dr. Vigouroux in his letter to your journal on April 30th. He says that the positive pad must be held by the operator, while the negative pad may be held by the patient.

In this case the water was the agent of both operator and patient. In short, according to my view, this is only another example of the hypnotic effect of the electric current.—Yours, &c.,

TÊTARD.

London, N., May 19th, 1886.

SCHANSCHIEFF'S SINGLE LIQUID BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am somewhat surprised that no mention has been made in *The Electrician* of Schanschieff's remarkable single liquid battery. A long and costly experience with primary batteries justifies me in saying that this is the most satisfactory and convenient yet invented. The liquid is an acid solution of sulphate of mercury, and from the sediment deposited by one gallon of it after use in a battery I recovered, by the simple process of squeezing through wash leather, 1lb. 10oz. of pure metallic mercury. The E.M.F. is quite constant until the solution is nearly exhausted, the reduction of the mercury being gradual and regular, while the zincs are of necessity kept bright and well amalgamated.—Yours, &c.,

G. CHRISTOPHER DAVIES.

Orwell House, Norwich, May 15, 1886.

MESSRS. GOOLDEN AND TROTTER'S LARGE DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you permit us to say, with reference to a paragraph in last week's *Electrician*, that the large* dynamos made by Messrs. Goolden and Trotter for the "Mersey" and "Severn," will not be driven, as stated, by Willans "six-cylinder compound engines," but by engines of the type known as "central-valve receiver engines." These are made under a recent patent of Mr. Willans, and are designed expressly for cases where extreme economy of fuel is required — as it naturally is on board ship, when dynamos are kept running day and night for incandescent lighting, and are not merely run occasionally for search lights. These engines are double-tandem, *i.e.*, they have two cranks, with high and low pressure cylinders to each, and variable cut-off gear. In justice to your informant, it should be added that Messrs. Goolden and Trotter are also supplying for the same ships two smaller dynamos, which are driven by three-tandem Willans compound engines of the type no doubt referred to as "six-cylinder engines"; but the dynamos actually referred to in the paragraph are, we believe, those driven by central-valve engines.—Yours, &c.,

WILLANS AND ROBINSON.

Thames Ditton, 18th May, 1886.

A STUDY OF INDUCTION.

BY SAMUEL E. PHILLIPS, F.C.S.

The following remarks were penned as a sequel to an extended examination of Prof. Gordon and Clerk Maxwell's views upon induction, and the electro-magnetic theory of light. They are now offered in an *inquiring* rather than in a dogmatic spirit:—

In aiming at clear thoughts and precise definitions, may we say that induction consists of 3 kinds?

(1) *Static induction* subsists wherever high tension effects are produced by frictional machines or otherwise, and the lines of force or polarity are either straight or more or less radiant, as dependent on conditions well understood.

As these static effects can be produced with high tension batteries where circuit or voltaism is prevented, so it is extremely probable that they subsist in more or less appreciable degrees wherever the + and − elements of chemistry evince a strain or tendency to combination.

(2) *Magnetic Induction* is familiarly known in the phenomena of magnetism. A moot question of very great interest occurs here, as to whether the lines of force of (1) and (2) are iden-

[* These should have been described as small dynamos compared with their large output.—ED. *E.*]

Digitized by Google

tical, or what is the *rationale* of their different behaviours. Let A B be the opposite plates of a condenser, and N S the opposite poles of a magnetic system.

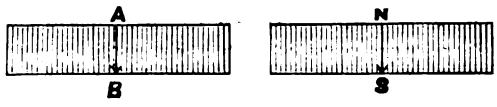

Fig. 1.

As to the similarly direct character of the lines of force in both cases there can be no question whatever. They both form, under similar conditions, radiant or curved lines. In both cases the opposite poles are attracted with a force varying as the square of the distance apart, the deviations from this law being similar in both cases.

Assuming that A is + and B −, does it also follow that N is + and S − ?

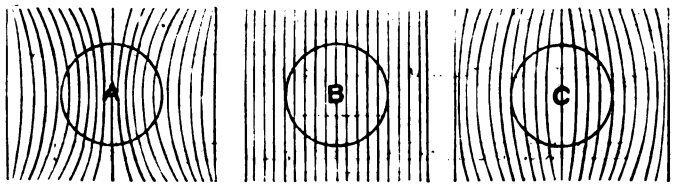

Fig. 2.

In A we have a good conductor, and the lines of force are diverted and condensed therein, the effect of which is to hold it strongly in the axial position as between two poles; it involves stable equilibrium. In B the lines neither condense nor open out; its conductivity is just that of the medium; and hence no outward manifestations of property. In C we have a bad conductor, and the lines of force are diverted and condensed in the medium, involving unstable equilibrium, with a tendency, if of more linear form, to be pushed aside or into a transverse position. A is called a para-magnetic, and C a dia-magnetic, and associated with these unfortunate terms a huge structure of wanton hypothesis has darkened the path of sound inquiry. This, however, needs a separate treatment; but it may be well to note in utmost brevity that Faraday, working with media of varied conductivities, and tubes of iron solution of varied strengths, showed that para- or dia- properties could easily be foreseen and produced accordingly, and Messrs. Gladstone and Tribe have subsequently elucidated the same principles of action in the liquid field of electrolysis, where suspended insertions of better conducting material than the medium have a stable equilibrium for the axial position, while worse conductors are pushed aside into the lines of weakest force, and behave precisely as dia-magnetics.

(3) *Electro-magnetic Induction* chiefly refers to that static or polar condition which surrounds every current of flowing electricity.

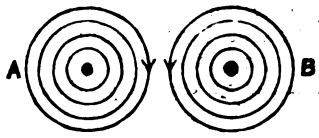

Fig. 3.

In A a positive current is supposed to be going down or away from the observer, when the lines of force or magnetism are directed as the hands of a watch move, viz., to the right. In B the current is reversed, or is supposed to be coming up, and the direction of the lines of force is opposite, or to the left.

It is a pure convention that the lines of force should be represented as going out of N and entering S, where it should always be clearly understood that in both cases there is no going out or motion at all under uniform conditions, the effect in both cases being a purely static one. In the magnetic case the direction, force, and character of the lines of force are familarly appreciable by placing or oscillating small magnets in the field.

In the electric case magnets do not so point, and the properties of the system are determinable by an electrometer.

In both cases, if air be the medium, there is no retentiveness of the polarity; but with rigid steel the retentiveness is very great, just as with rigid glass in the other case the polarity is considerably retained, and the residual discharges would be more prolonged if the medium were thicker.

In both cases the lines of force behave similarly with different media. In other words, they are dependent on rates of conductivity. In the electric case taking air as standard or unity = 1, then the conductivity of shellac for this polar force is 2, or double that of air. But there is considerable vagueness as to the methods of obtaining these determinations.

Mr. Gordon, with Clerk Maxwell, estimated "double extra-dense flint glass" to be 3·838; but Dr. Hopkinson well maintains that its capacity, or, as I prefer to call it, its conductivity, is nearly tenfold that of air.

In the magnetic case this vagueness is yet more predominant, and the phenomena is *so relative* that absolute determinations are a great mistake. But the fundamental facts are simple and familiar. Bismuth possesses the lowest conductivity; but that varies greatly under different conditions. Air is a better conductor, and iron enormously the best. In principle diagram 2 applies to both lines of force; but it is more usual to regard them from the magnetic point of view.

Here we have several conventions which are purely such; but they are necessary and very convenient. Of course the setting up of these curves tends to produce an opposite current in the wire, involving a counter E.M.F., or increased resistance during the variable period; and *inversely* on stopping the current, the fall to zero of these magnetic lines induces in the wire an "extra current" in the same direction as that which produced the system. These are not opinions, but facts which can easily be verified. This inductive action admits of being increased in two ways—firstly, by self-induction, and, secondly, by increasing the conductivity of the media.

By self-induction we mean that increase of inductive effect, inherent upon a condensation of the magnetic field, when the wire, instead of being straight, is wound into a coil, and the convolutions are allowed to act upon each other. It is easy to see that this proximity of convolutions in the same wire must increase the counter E.M.F. we have described.

I feel justified in making no comment on the Hughes research, because some high authorities have maintained that it leaves intact the previously established "electro-dynamic laws." Mr. O. Heaviside says: "I have failed to find herein any departure from the known laws of electro-magnetism." But I cannot help remarking that throughout the discussion the utmost vagueness has subsisted in the use of terms. As the word "self-induction" had a previous existence, such as I have described, *if* Mr. Hughes has added another element, it seems more feasible to have called it *internal induction*—an action in the substance of the wire, as distinguished from that of the surrounding media. Secondly. By increasing the conductivity of the media, we greatly enhance the inductive effect. We first of all have an inherent inductivity in the wire, or, more correctly, in the current passing along the wire, because the same thing equally subsists in the battery fluid; then we find an increase by winding the wire into a coil, so as to make an air magnet; and, last of all, a greater increase of the force, by placing iron in the coil. Using the conventions before referred to, we can now see that a right-handed spiral conveying a positive current from A will produce a S pole at the nearest end thus

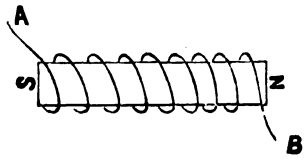

Fig. 4.

We have said that setting up this polarity induces a counter E.M.F. against the current; but, as this cannot be directly recognised, we now essay to prove the fact. Let the two ends

Digitized by Google

A and B be connected through a galvanometer, and the N S polarity be induced by a stronger external magnetism; we then find a current induced in the wire, in the contrary direction to that which would have induced the given polarity; and further, on the sudden withdrawal of the constraint, the fall of this polarity to zero will induce an opposite current in the wire, viz., the extra current of Faraday.

In place of the present vagueness it is high time that we should have some strict, or, at any rate, approximative measurements of the "variable period," say, in a mile of aerial wire; and, secondly, of the percentages of elongation due to the wire being coiled round an air magnet, and also with iron core; and, lastly, the length of this period in, say, a mile of submerged wire. I know of no one better fitted for the accomplishment of this work than Mr. Willoughby Smith, who, probably, has all the materials necessary for a definite determination. This brings me to my last point, viz., What is the nature of the induction in a submarine wire?

It is a complex of (1) and (3), and, strange to say, it is mostly (1). We cannot utterly exclude (3), because "electromagnetic induction" is but another term for "current induction;" but this affection with its directive tendencies is minimised by a thin field of dielectric, and it is immensely overpowered by No. (1), or static induction, with a non-directive accumulation. It is popularly and very properly considered a condenser; but it has this difference, that the conducting wire, or circular plate, is very elongated, and the charge set up thereon varies as the potential at any given distance from the source of power.

Given two small condensers, of similar capacity, one charged to one volt and the other to two volts potential, we then find that the quantities of electricity charged upon these similar surfaces will be as one to two, and precisely thus it is with a submarine condenser. Let us assume a potential of 10 volts at one end, and zero, or earth, at the distant end.

Fig. 5.

It then follows, if we divide this length into equal parts, that the geometrical areas of tension will be as 1, 3, 5, 7, &c.; and that at any given instant of charge the quantities of electricity held or induced in these sections will be as 1, 3, 5, 7, &c.

There is a curious distinction between the induced transverse or right-angled lines of force (3), and the direct lines of static induction (1). The former are irrespective of tension or potential, and only dependent on the quantity of electricity flowing, whereas the latter are wholly dependent on potential. The magnetic induction along the line A B is a constant at every point, and we may have a parallel circuit with 10, 100, or 1,000 times the quantity of electricity flowing, as is familiar in a Bridge circuit, but if the two be connected at points of equal potential, no current will flow from the many to the few lines of force, or from the strong magnetism to the weak; and, conversely, may we not say that the static lines of force will be the same in both circuits, from the same source, though one may carry 10 amperes and the other 1,000?

SMOKE CONDENSED BY MEANS OF ELECTRICITY.

From Tyndall's experiments on the dust found in the air, Messrs. Clark and Lodge observed that a body at a higher temperature than its surrounding medium is enveloped in a thin stratum of air absolutely free from dust.

Dr. Lodge, of Liverpool, conceived the idea of studying this phenomenon, making use of electricity; he remarked that electrical discharges produced at high tension by a statical machine possessed the property of condensing dust and smoke of all kinds.

This was not slow in finding a ready application in metallurgy, for condensing the dangerous fumes and dust of lead in the factory of Messrs. Walker, Parker, and Co., one of the largest of its kind in England. The results secured were remarkable, and the attention of students was particularly called to this new method of treatment, because it had a twofold bearing—on the health of the workmen and on the economy of the process.

The experiments of Dr. Lodge are of that class which will in time become classical, and which should be made public. It was with this object that the two devices illustrated (Figs. 1 and 2) were constructed. The larger apparatus is designed to show the effect of electricity upon smoke in motion (Fig. 1). It is provided with a furnace, in which may be burned the materials for producing the smoke. The fumes first pass into a box having glass sides, which enable us to see what is going on inside. This is connected with another box of the same kind by means of a horizontal glass tube. The second box has a tube at its top and a device for regulating the draught. Each of the boxes in its opposite sides is provided with brass combs, which are connected with the opposite poles of a Toepler-Voss, a Ramsden, or Holtz electrical machine.

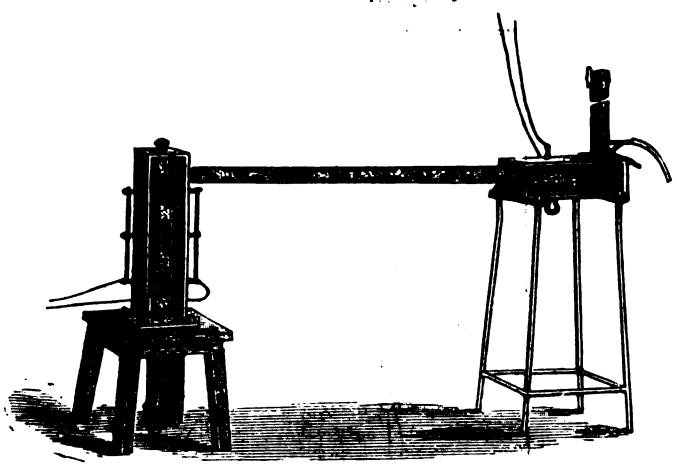

Fig. 1.—Large Apparatus for Condensing Smoke by Electricity.

German tinder, for instance, is put into the furnace. The thick smoke which it produces passes through the whole apparatus. If the electrical machine is now put in motion until the sparks pass between the combs, immediately the smoke becomes agitated, and in a little while will disappear by condensation. The boxes and tube become as transparent as before the experiment. The smoke of German tinder can be advantageously replaced by that which is produced by the combination of hydrochloric acid and ammonia. The white thick smoke of hydrochlorate of ammonia condenses very rapidly on the electrified combs.

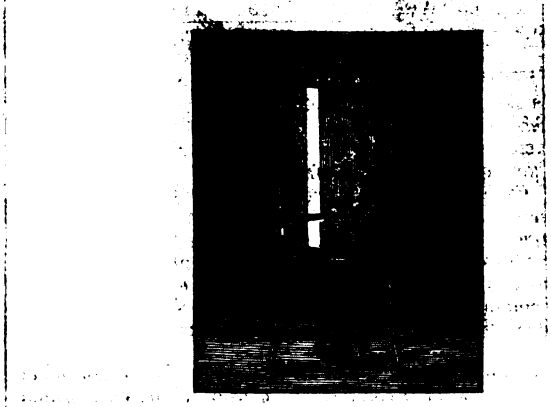

Fig. 2.—Small Apparatus for Condensing Smoke by Electricity.

The smaller apparatus (Fig. 2) is much more practicable for experiment. It shows the effect of electricity on smoke at rest, and gives a clear idea of the phenomenon. It consists in a glass cylinder having openings in its side, through which are passed the metallic combs. It is mounted on three feet, and is provided with the furnace for producing the smoke. The draught is maintained through the tube in the top of the chamber. Paper treated with nitre or German tinder is burned in the furnace, or else the vapours upon which the experiment is to be made are liberated by some chemical reaction. When the glass cylinder is full of smoke, the machine connected with the combs is put in motion, and the vase, smoky and cloudy, immediately becomes clear and transparent, the vapours being condensed. Tobacco smoke is very quickly and easily condensed by means of this machine.

These phenomena are remarkable. They appeal at once to the savant, the artisan, the student of hygiene, and demonstrate how infinite is the field of discovery.—Gascon Tissandier in *La Nature*.

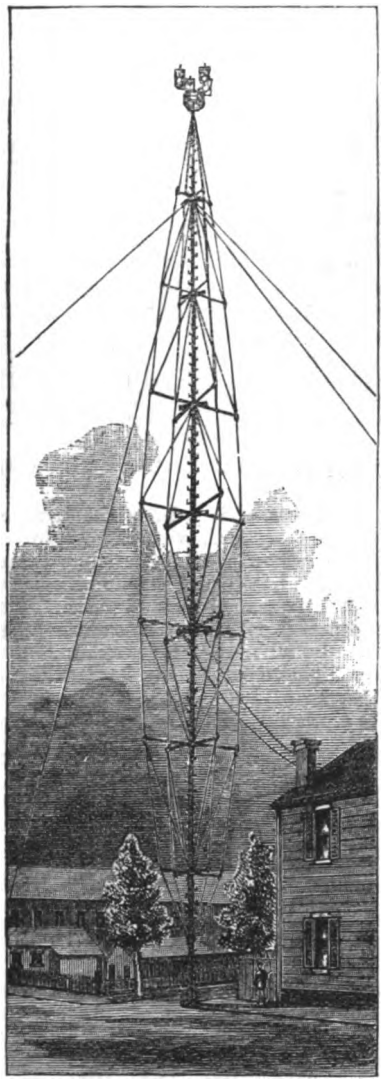
A NEW ELECTRIC LIGHT TOWER AND IMPROVED DYNAMO.

City lighting by means of arc lamps placed upon towers seems to be gaining favour very rapidly, especially in our Western cities. The placing of a number of powerfnl lamps in elevated positions has the advantage of distributing the light more evenly over a larger area than would be possible with a similar number of lamps near the surface. Taking into consideration, also, the fact that the cavity formed in the upper positive carbon causes a large portion of the light to be projected downward in the form of a cone, it is apparent that with lamps near the surface the immediate vicinity of the lamp post receives the most intense light, to the detriment of the illumination of outlying space.



The introduction and use of tower structures has been somewhat hindered by the materially increased first cost of plant consequent upon their use, and by the obstruction of the streets by the foundations and lower framework of some of the early forms of these towers.

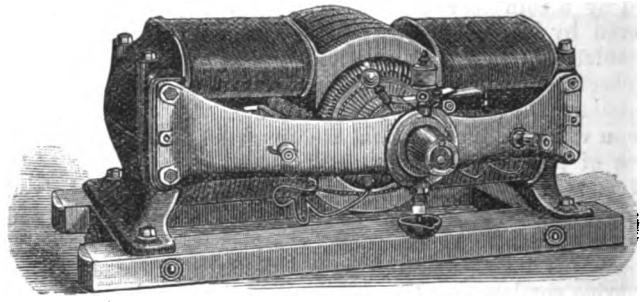
Notwithstanding these hindrances, the tower system has grown rapidly in public favour, and there are now in use in this country nearly three hundred electric light towers, with a fair prospect that the number will be largely increased before the close of the present year.

Among the towers of recent design is the one illustrated in the accompanying engraving, devised by Mr. P. S. Adams, of the Jenney Electric Company, of Indianapolis, Ind. The height of this tower is 125ft., and it is designed specially for strength and to prevent the obstruction of the streets. People are learning that the additional first cost of plant, with towers, is much more than compensated for by the superior quality of the light and by the increased area illuminated thereby.

The tower illustrated in the above engraving is, as stated, 125ft. in height, and embodies numerous improvements designed to cheapen the processes of manufacture and erection, to give strength and beauty to the structure, and to leave the streets clear for traffic. The lamps are supported in iron frames, mounted upon pivoted arms extending from the railing posts of the trimmer's platform. This arrangement greatly reduces the amount of wind surface at the top of the tower, and of shadow at its base, permits the use of any desired number of lamps, and adds materially to the appearance of the structure. The tower structure consists of a central vertical mast, in 16ft. sections, trussed by horizontal struts and vertical and diagonal brace rods or ties. It is supported by means of guys of galvanised wire rope, connected to suitable guy posts, firmly set at the kerb line of the side walks, the whole forming a trussed structure of great strength and neatness.

The Jenney Electric Company, of Indianapolis, has also lately made several improvements and changes in the form of its dynamo, which we illustrate below as it now appears. As will be seen, the arm which carries the armature consists of a rigid casting extending from end to end of the field-magnets, and bolted to the latter at their neutral points. This construction permits of the use of long overlapping field-magnets, without entailing the use of a needlessly long armature shaft.

Another feature in this construction is the fact that the greatest strength of the arm lies in the direction of the pull of the belt. Fitted in these arms are self-adjusting swivel-boxes or bearings for the armature shaft, provided with sight-feed, automatic oil cups, so arranged that each drop of oil fed to the bearings can be seen, thus enabling the operator to be sure whether the bearings are being lubricated or not.



The boxes themselves are babbited and reamed out to an accurate size, are interchangeable, and can be removed from the machine and replaced without disturbing the armature or removing the arm. *Electrical World.*

ELECTRIC LIGHT IN THE SUEZ CANAL.

A correspondent of the *Daily News* writes the following account of the passage of the Peninsular and Oriental Company's steamer "Carthage" through the Suez Canal at night by means of the electric light, which is a much fuller account than has before appeared:—

"Soon after our leaving Malta it became evident preparations of an unusual kind were being made. A large iron tank was brought up from the hold; coils of wire lay about; lamps with a more powerful lens than usual, and various gear not often seen on board ship were produced. The ship's carpenters were busy making what appeared to be a miniature platform; while the noise of the hammer and rush of steam disturbed the usual quiet. Then for the first time the announcement was made that it had been decided to attempt to make the passage of the Suez Canal at night by means of electric light, and some preliminary experiments were to be made in order to test the electrical gear taken on board in London. After trying the dynamo and engine the most important point was to decide upon the best place to fix the projector. Experts are not agreed upon this; and unfortunately the roughness of the sea did not admit of a trial being made with the light low down in front of the stem—the position Captain Hector thought most suitable. Up to the present all vessels passing through the canal have been compelled to tie up at sunset, and remain moored to the banks until sunrise. The actual channel being so narrow it would be impossible for steamers of deep draught to steer correctly in an uncertain light. The directors restrict the hours for transit to the daytime, and thus have kept the water-way comparatively free from accidents. Delay was inevitable, and was shared by all alike. Recently the Board of Control so far rescinded this rule as to permit steamers properly fitted with electric light to pass through at night. Months passed before any of the shipping companies availed themselves of this facility, until the Peninsular and Oriental Co. decided to make the experiment, and fixed upon this magnificent steamer of 5,000 tons burden as the pioneer, and gave Captain Hector a free hand in regard to all arrangements. Port Said was reached at 5:30 p.m. on the 22nd inst., where most of the canal authorities from their headquarters had come down to wait our arrival. It had been doubted whether it was practicable to navigate a large vessel through the winding parts of the canal by an artificial light, so that many of the officials were anxious to watch this first trial. M. Desavery, chef du service; M. Rumeau, sous chef; Captain Tillier, and eight of the senior pilots joined us at Port Said. All the gear had been got into position ready for use. An engine of 12 horse-power had been fixed near the forecastle, and a stage of about 4ft. by 6ft. swung over the

Digitized by Google

bows and lashed about 14ft. above the water. The projector was fixed about the centre of the platform, and placed under the charge of the electrician in chief and a seaman. The engine and dynamo were worked by the assistant electrician and an engineer. Each side of the steamer carried an electric lamp, to be used in case of need, and another was hung over the stern. About 8 p.m. everything was in readiness. The light was tested for about ten minutes, and the current found to be steady and continuous. Crowds of dark faces from the banks and from other vessels curiously watched the novel sight as the huge steamer, throwing forward a dazzling light, quietly slipped from the mooring buoy and slowly made for the head of the canal. The cross lights from the shipping and town must have been disturbing to those who were piloting us, especially as a steamer right ahead hid the entrance from view. After passing it we saw that the two buoys that mark the entrance to the canal had been lighted, to prevent any difficulty in finding the channel. The full efficiency of the light was not apparent until the glare of the town had been left behind; then it was found the illuminating power was such that the buoys could be distinguished more than 500 yards ahead. Light was also needed close to the vessel, and the arc of dispersion was arranged to include the buoys within a few feet of the bows; at a slightly increased distance the rays extended to the banks. In portions of the canal where the banks are high the dry white sand threw back upon the water the spreading rays, perceptibly increasing the illuminating power. For the first hour there was no moon; subsequently the light was a doubtful advantage. In the early hours of the morning a dredger, not showing the regulation lights, occasioned a considerable delay. Perhaps the most difficult part was steering a vessel 430ft. long, drawing 24½ft. of water, between the high banks and sharp curves just before Ismailia, in a channel not more than 80ft. wide and only 26ft. deep, solely by means of a light projected from the vessel itself. By forethought and skilful pilotage it was accomplished without an accident of any kind, and it proved the wisdom of the captain's determination to make the trial with one light fixed low down on the stem, instead of placing it on the foreyard or having one on each side. Ismailia, situated about half-way through the canal, was reached soon after five in the morning. Daylight was available for the rest of the distance, and the steamer anchored in Suez Harbour soon after 2 p.m. on March 23. Thus the actual passage of the Canal was made in eighteen hours, but when the two hours' delay are deducted it leaves sixteen hours for actual steaming. All travellers to India, China, and Australia will appreciate the immense saving in time thus effected, and in times of quarantine in Egypt the mails will be passed through with much less delay. The complete success of the trial has convinced the Canal authorities that the largest vessels can, under efficient management, be navigated at night. Few steamers make the passage under two days, but by the enterprise of one of our leading shipping companies and by the skill of their officers it has been conclusively demonstrated that at least a full day can be saved by Eastward bound vessels."

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The meeting of this Society, after the Easter recess, was resumed on Thursday evening, 13th inst., at the Institution of Civil Engineers, Gt. George-street, Prof. HUGHES in the chair. It was announced by the Secretary that a petition had been presented to Parliament embodying the views of the Society with reference to the Electric Lighting Act Amendment Bills now under discussion, namely, that no Act of the kind would be deemed satisfactory which did not place the electric lighting industry on the same footing as gas lighting.

Mr. W. H. PREECE, F.R.S., then delivered an address upon "Long-Distance Telephony." First explaining that although his subject was one dealing not so much with the problem How far can we telephone? as with the question How much we can telephone? between places widely apart, and on purely commercial principles, Mr. Preece intended to confine himself mainly to trunk wire working as distinguished from local working. Long-distance telephony in America was called "extra-territorial," meaning beyond the boundary of concessional rights of the various companies. It was also called "toll line" work, meaning that conversation could be held by telephone on payment of a toll, as distinct from the system of subscription applicable to local telephony. In Belgium the system was called inter-urban, a very good designation, which would apply very well to this country also. How far commercially a success wherever it had been tried was a doubtful matter, although indirectly no doubt it had been found worth while to introduce and extend it. The difficulty attending it was not one of apparatus. But, as a matter of fact, very few improvements—except in switches and bells, which he was not then considering—had been made in telephonic appliances on the original Bell receiver first brought to England by him (Mr. Preece), and scarcely any in the microphone transmitter invented by the Society's president. Different tunes had been played with these great inventions, but all upon the old strings of Bell, Edison, and Hughes. And with regard to Edison, ingenious as his devices undoubtedly were, those that had come into practical use were based on Hughes's discovery, not on the Edison patents. Many had been the inventions, so called, and patents without number, and the cry is still they come; but there was hardly anything novel about them, and nothing that was commercially valuable. The apparatus actually in use was sufficient for its purpose provided it was properly worked, and the wires attached to it erected with due regard to the indispensable conditions of telephonic working. Yet it was undoubtedly the fact that in this country there was nothing like the amount of long-distance telephoning that prevailed in the United States and on the Continent of Europe. And the progress of telephony in general was also far greater elsewhere than here. In the States at the beginning of 1877 there were no telephones on hire. Before the end of that year there were 780. In 1880, only three years later, there were 60,800 telephones in use, and 100 exchanges. In 1883 the number of telephones had increased to nearly 250,000; and at the end of last year the total had reached 325,750, and there were 782 exchanges. In Canada similarly, where there was a population of under three millions, no fewer than 18,000 telephones were on hire. Compare these figures with those for England, where in December, 1885, only 13,000 telephones had come into operation. In the capitals of Europe the same contrast appeared. Berlin stood at the top with 4,248 subscribers; whilst London with its enormous population had only 4,103, and barely exceeded Paris with 4,054. Even the small city of Stockholm possessed 3,825 telephone subscribers; whilst Liverpool, Glasgow, and similar places in England numbered about 1,100 each. It is, therefore, evident that from some cause or other telephony has made not nearly the progress in England that it has in other countries. [Here Mr. BRIGHT interjected "Charges;" an explanation which Mr. PREECE rejected, pointing out that the charges were actually less in this country and the restrictions fewer than in the States.]

Coming now more closely to the subject of telephoning over long distances there was, he said, no serious difficulty attending it considered as a mere electrical problem. On first bringing over the Bell telephone to this country, he tried it with success through 60 miles of cable between Dartmouth and Guernsey; afterwards on the longer cable from Holyhead to Dublin; and he well remembered on that occasion the late Mr. Sanger, when asked "Can you hear my voice?" replying quite distinctly, "Yes, and smell your cigar!" Further experiments proved, however, that upon a cable of the pattern of the Atlantic ones, 20 miles was the limit to which intelligible speech could be carried on. Lord Rayleigh has since confirmed this conclusion on theoretical grounds. With land lines, however, far greater distances have been traversed. In Persia they had conversed at a distance of 390 miles; in India at 500 miles; and in America 1,000. It was therefore not, he repeated, a question of apparatus, but of the conductor and its environment. The lecturer then described in detail all the known forms of inductive and other disturbances to which telephone lines are liable, especially when in contiguity to telegraph wires, or to electric lighting wires in towns; all tending to blurr the sounds of telephonic articulation, enfeeble, and finally obliterate them. And this it was important to observe happens on short circuits as well as on long ones. Audible disturbances are easily eliminated. The Post Office had effected this by employing metallic circuits of twisted wire. Nevertheless, we cannot speak beyond certain distances. At Newcastle they had gradually increased the limit of commercial working to 20 miles with underground wires. Thirty-nine miles had been spoken through, but ordinarily 20 miles was the limit. As regards overhead wires, the Post Office had erected four wires from London to Liverpool and Manchester; they were No. 8 iron wires, and on the twist principle. They worked well for a limited distance; at 150 miles the articulation was not satisfactory; at 170 it was possible to speak, but not commercially practicable; and at 200 there was nothing but low rumbling sounds. Since Prof. Hughes's paper on this subject, it appeared that had these wires been of copper, speech would have been practicable throughout the whole length.

Reverting to the commercial aspects of inter-urban telephony, Mr. Preece described the system as worked in America and Belgium, the latter on the Van Rysselberghe plan, which has been fully explained and illustrated in these pages. The single wire system prevails in the States, as is evident from a comparison of the mileage of poles and wires. A toll of 25 cents. is charged for five minutes' conversation. He had found by personal trial of some of these lines that they did not all work satisfactorily. Between Chicago and Milwaukee this was the case. Between Michigan and Boston, a far greater distance, the speaking was good, but this was a metallic circuit of copper wires. A curious plan for obtaining capital to erect these inter-urban lines had been resorted to in the States. Toll tickets are sold beforehand, and as soon as the required amount has been raised in this way the work is completed and the purchasers of toll tickets are, of course, entitled to expend them in conversation, which accordingly they do without stint. Notwithstanding this artificial aid to long-distance telephony, the result is not particularly encouraging as regards customers, and it certainly does not pay except indirectly by attracting subscribers to the local exchanges. Here in England the United Telephone Company had only one trunk line of this kind, that between London

Digitized by Google

and Brighton. Outside the influence of this powerful company, however, in Lancashire notably, a great number of such lines had been erected, as also in Scotland. These lines were said to be doing a fair business. But the most complete system was to be found in Belgium under the management of the Government. who had left local telephony to the operations of private companies. Van Rysselburghe's method had been introduced there, and had eliminated induction or rendered it innocuous. The sudden rise and fall of current in Morse signalling were slowed down by inserting condensers and electro-magnets, so that they do not appreciably disturb the telephone. The inventor appeared to have got the idea by observing that the telegraph signals from Brussels to London had a bad effect on telephone lines, whereas those coming from London were harmless. Every circuit in Belgium is, therefore, armed with these anti-induction appliances, and the result is that even busy circuits are available for inter-urban telephony, it being practicable to carry on the two operations on the self-same wire. France has partially adopted this system, which has probably a great future before it on the Continent.

Now, why, it may be asked, cannot we do the same thing here? Firstly, because every circuit so armed is a cause of retardation, which matters little on circuits working slowly, but becomes serious when a normal speed of 250 or 300 words a minute gets reduced to, say, 150. Such would be its effect on fast-speed working in this country, and we cannot afford to sacrifice speed in telegraphy for the minor advantage of efficiency in telephony. Then, secondly, there are the independent railway telegraph systems over which there is no Governmental control; and, lastly, there is no sufficient grounds for supposing that the inter-urban system, even if practicable, would be a commercial success. Mr. Preece then described the Post Office idea of telephony as exemplified in the admirable network of communication established at Newcastle and neighbourhood by Mr. Heaviside. Double wires are employed, and are worked on what is called the "bridge" principle. Government telegraphs as such are not liked by some people, but he claimed for the Post Office a preponderance of improvements, and the contrast which England presented to the rest of the telephoning world was due to the crushing and grasping monopoly chiefly of one great private company [loud cheers]. Its patents, however, would expire in due time, and the existing hindrances to telephonic progress would then be removed.

Mr. Van Rysselberghe offered, with the approval of the Society, to bring before its notice a full description of his system on some future occasion. He might mention, however, that besides the great successes it had achieved in Belgium and France, the results of practical trials over far greater distances in America were most encouraging. He found that iron wires were worthless for distances over 150 miles; all the high notes were reduced to bass, and the sibilants consequently lost. On copper covered steel wires, 1,000 and 2,000 miles long, articulation was perfect. Each country had no doubt its special local conditions to be considered; but as regards the commercial aspect of the question he believed the system would pay, and cited the case of Brussels and Antwerp, between which places 150 telephonic messages passed every day. In the course of his observations Mr Van Rysselberghe claimed for an Englishman, the late Cromwell F. Varley, the distinction of being the first inventor of the telephone.

Prof. Silvanus Thompson repeated his previously-expresssed opinion that the great defects of our telephonic systems were the over sensitiveness of the receiver, the feebleness of the transmitter, and the low resistance of the wire. He thought that two of our countrymen in Canada had gone a very great way towards solving the problem of long-distance telephony.

After some remarks from Mr. Blakesley, Mr. W. H. Preece having briefly replied, expressing his dissent from the opinions of Prof. S. Thompson, the proceedings terminated.

PROF. FORBES' CANTOR LECTURES.

(Continued from page 523.)

LECTURE III.

In my last two lectures I spoke about statical electricity and about a current of electricity, and I mentioned that there was a time when it was absolutely necessary to prove that these two manifestations of electrical influence were identical. Now, there is no doubt about it. We know that statical electricity and dynamic electricity are identical; that there are not two kinds of electricity, but that the phenomena we studied on the occasion of the first lecture and the phenomena we considered on the occasion of the second lecture are really different manifestations of one identical force. To-day I am going to describe to you some of the principal phenomena of magnetism, and we shall find that here also we are dealing with simply another manifestation of this same electrical force. The latest development of the theories of magnetism, in fact, do actually go to prove that magnetism is simply due to a large number of small electrical currents. But about that we shall be able to say something more towards the close of the lecture. The facts in connection with magnetism which were known in days of old were very limited indeed. In fact, it seems remarkable that the discovery of the mariner's compass should have been delayed to so late a period in the world's history as it was. In various parts of the world occasionally pieces of mineral, largely composed of iron, are found which have this peculiar property—that when suspended by means of a thread they point in a north and south direction, if they are not disturbed by the presence of other pieces of iron in the neighbourhood. Here is a piece of loadstone which is marked at the two ends with a blue and red mark to show the extremities of the axis, which must be made horizontal. Then, suspending it by a thread so that the axis remains horizontal, we see that the main direction of the loadstone from one pole to the other remains in the magnetic meridian—that is to say, in a north and south direction. There is another property in connection with the loadstone, which is this—that two different pieces of loadstone influence each other, that they produce a movement of attraction or repulsion. Thus, when I take a piece of loadstone, and bring it into the neighbourhood of another which is suspended, you see it immediately turning round, showing that there is an influence between the pole I presented to it, and the pole of the suspended magnet. I have commenced these remarks by speaking about the loadstone, because that is really the commencement of where we find our magnetism. But in our experiments which we may perform in the laboratory, instead of using pieces of natural loadstone such as are found already magnetised, it is much more convenient in general to use a magnet such as I have here [shown], and which I can suspend upon a pivot. A needle thus magnetised will set itself naturally in a north and south direction, and can be acted upon by another magnet brought near it so as to cause repulsion between the two similarly coloured poles. We shall likewise have attraction between the red pole of one magnet and the blue pole of another. These bars of magnetised steel have been marked so that the red end points towards the north, and this is what we have arrived at by this experiment, that we show that the two north ends of the magnets repel each other, and the two south ends repel each other, but that the south end of the one attracts the north end of the other. This is generally expressed by saying that like magnetisms repel each other, and unlike magnetisms attract each other. I have been speaking about the north end of this needle, and as there is some confusion in naming these poles it would be right to say when I speak of the north end of the compass—the end of the needle or magnet—I mean the end nearest to the north. It has been sometimes thought advisable to call the north end of a compass needle the other end, because in all probability the earth acts as a huge magnet, in which there is one kind of magnetism more prevalent in the northern hemisphere, and one kind more prevalent in the southern hemisphere, and it has been proposed by some that we should call that the north kind of magnetism which is in the northern half of the earth. There has been a great deal of controversy about what is the right terminology to use, and Sir William Thomson has said it is impossible to instil into the head of the ordinary investigator that the north pole of the earth has south magnetism in it. But it has always seemed to me much more difficult to instil into the head of the ordinary seaman the idea that the north end of the compass needle has south polarity; and I think it really seems more advisable to speak about the north end of the compass needle as being the end which points towards the north. We have arrived, then, at this general result, that the north end of a magnet repels the north end of another magnet, and that the south end of a magnet repels the south end of another, but that the north and south mutually attract each other. This action between a suspended magnet and another magnet is identically of the same nature as the action which takes place between the whole mass of the earth and a suspended needle. A suspended magnet tends to place itself in a north and south direction, the reason being that the whole earth acts in the same manner as this magnet which I hold in my hand does. When I hold a magnet near a suspended magnetised needle it tends to give a certain direction to the needle. The action of the earth is of the same nature, and it is due to the fact that the earth is magnetised as a whole, or that there is a sufficient quantity of iron in this magnetic condition in the earth, that we have the most valuable property of the compass needle, viz., that it points north and south. It was noticed in the seventeenth century that there is another action due to the earth's magnetism besides the attraction of the magnetic needle into a north and south position. It was noticed by Norman that if we take a bar of steel pivoted accurately at its centre of gravity, so that it ought to naturally rest equally in every direction, then the end which points to the north will also incline downwards at a considerable angle, and here I have such a needle, which I place in the magnetic meridian fairly suspended on the pivot, and free to take up any position in the magnetic meridian. That compass needle, as you will notice, points at a very great angle—something like 70 degrees—to the horizon. This is spoken of as the dip of the compass needle. Gilbert, who was the father of the science of magnetism, wrote a great deal about this, and pointed out that the dip of the needle might be explained simply by supposing that the earth was acting as a magnet. Gilbert said, "If we have a magnet going through the earth, or only a short magnet at its centre, it will attract the suspended magnet, and the tendency will be for the magnet placed in the equator to rest horizontally." But if we were to bring the same needle up to, say, the latitude of London, then the end of it, which was attracted by the pole of the magnet in the centre of the earth, would point downwards. Therefore, we should have the compass needle, when suspended at the centre of gravity, not lying horizontally, but dipping down towards the horizon, and this will explain the dip of the needle, namely, that its attractive action is due to the magnetised portions of the earth. Gilbert had no more knowledge about dip than the fact that in these latitudes the dip was about 70 degrees. But he saw, if his explanation was correct, that the dip would vary in different parts of the earth, that at the north pole of the earth the needle would dip vertically downwards, that at the equator it would be parallel to the horizon, and that the inclination would gradually change from the vertical to the horizontal as we passed from one of the poles to

Digitized by Google

the equator. This was a prediction by Gilbert, which was completely verified when the experiments were made in different parts of the earth. A spot near the North Pole, where the dipping needle is perfectly vertical, has actually been visited by Arctic explorers. When I was speaking to you about a statical electrified body, I told you that there were two kinds of forces that come into play. One was a true force, which caused a motion in a material body; the other was not what Newton would have called a force, because it did not produce a motion in the body, but produced a motion of electrification. That force we call electromotive force, and electromotive force produces a change in the electrical condition of bodies. We have an exactly similar thing in the case of magnetism. Whenever there is a magnet in the neighbourhood of any point of space it is producing a force of this peculiar kind—not only a force that will produce motion in a body, but a force tending to produce a rearrangement of the magnetic condition. We shall see a little more clearly how this acts presently. But as we study the question of magnetism more fully we shall find that all the magnetic phenomena are produced by the action of forces which are able to rearrange the condition of magnetism in iron bodies, and those forces are trying to change the condition of magnetism in those iron bodies. If the bodies offer a sufficiently small resistance, then the change in the condition of magnetism can take place. If they offer a large resistance the change cannot take place. But the analogy is most remarkable between that which we might call magnetomotive force, and what we have spoken of as electromotive force. The resistance which iron or other bodies oppose to a rearrangement of the magnetic state is exactly analogous to the resistance which is offered by different materials, either conductors or non-conductors, to a rearrangement of the electrical condition when a body is subjected to the action of electromotive force.

(To be continued.)

LEGAL INTELLIGENCE.

The Edison and Swan United Electric Light Company and others v. Woodhouse and Rawson.

The trial of this important patent action, which occupied the whole of last week, was continued on Saturday and Monday. The action was originally based upon three patents, but has been considerably narrowed, there being, as the Judge thinks, no evidence to go to a jury as to the infringement of Swan's patent and the minor patent of Ginningham. The trial, as now narrowed, chiefly relates to the second of four claims in a patent of Mr. Edison, dating from November, 1878. The first claim is for a lamp with a filament of carbon of high resistance, made as described, secured to metallic wires as set forth. The mode of securing wires described in the patent has been superseded. The second claim is for "the combination of carbon filament" (not, it is to be observed, as in the first claim made as described) "within a receiver made entirely of glass, through which the leading wires pass, and from which receiver the air is exhausted for the purpose set forth."

Counsel for the plaintiffs are Mr. Aston, Q.C., Sir R. E. Webster, Q.C., Mr. Moulton, Q.C., and Mr. P. Edward Dove; for the defendants, the Solicitor-General (Sir Horace Davey, Q.C.), Mr. Charles, Q.C., Mr. Macrory, and Mr. H. G. Rawson.

Dr. FRANKLAND, the first witness for the defendants, was examined on Saturday by Mr. Macrory. He was taken through the several patents relied on as anticipations, beginning at King's patent in 1845 for an incandescent lamp by means of a carbon burner in a Torricellian vacuum. He considered the chief difference between the older attempted lamps and Edison's lamp, as described in principle, was that the older lamps had not globes entirely of glass, and thus failed because other events in science, such as the invention and improvement of the dynamo, had taken place since. He gave results of his own in producing carbon filaments by coating a strip of boxwood with thread and paper according to Sidot's process, by which he produced a flexible and uniform carbon filament instead of the unevenly coated filament that Prof. Dewar had produced. He had worked, he said, with a hydro-carbon that contained comparatively little carbon, under 40 per cent., while Prof. Dewar employed benzine, which contains over 90 per cent. His process occupied three hours, while Prof. Dewar's occupied only one.

The cross-examination of Dr. Frankland by Mr. ASTON, Q.C., which had begun on Saturday, was completed to-day, and he was re-examined by the SOLICITOR-GENERAL.

Principal Jamieson, of Glasgow, in his capacity of a practical electrician, was examined by Mr. MACRORY, cross-examined by Mr. ASTON, Q.C., and re-examined by Mr. CHARLES, Q.C., and the examination in chief of Dr. Odling by Mr. CHARLES, Q.C., was commenced. Principal Jamieson gives it as his opinion that some of the prior specifications gave a sufficient description of how to make as good a practical carbon glow lamp as Edison's, which he considered was imperfect. He said that there was not enough in the specification to tell a practical workman how to get a proper carbonised filament for the purposes of glow electric lighting, though he agreed with Dr. Frankland that a filament would be properly carbonised according to Sidot's process, which was published in 1870, but that was not known to an ordinary workman. He also said the platinum wires, which are sealed through the glass receiver or lamp, would only at that time be sealed in a manner that would not stand long enough under the strain of change of heat to be commercially successful; and, in the third place, that Edison's description of how to make a lamp was insufficient, inasmuch as it did not direct the workman to "run on the pump" while making the vacuum. He said the knowledge on the subject had not advanced sufficiently to make a really good lamp till about the end of 1880, a year after Edison's patent in question was provisionally taken out.

The trial was continued on Tuesday. The evidence of Dr. Odling, the third of the defendants' expert witnesses, was completed. Mr. Rawson, one of the defendants, was examined. He said their lamp contained a carbon burner of small sectional area, the method and process of preparing which was a trade secret, the maintenance of which was essential to their successful manufacture. He said it was made under a process discovered since the date of the plaintiffs' patent.

The SOLICITOR-GENERAL very shortly summed up his case. He dealt with the second claim of the Edison patent of November, 1879, the trial having been almost narrowed to the consideration of that claim. It is for the combination of "a carbon filament within a receiver made entirely of glass, through which the leading wires pass, and from which receiver the air is exhausted for the purpose set forth." The Solicitor-General said that either "filament" must be construed in the less natural sense of a carbon filament made according to the mode of manufacture described by Edison, and in that case there was no infringement, or if, on the other hand, the word was to be construed as meaning any filament, considering the state of knowledge with respect to electric lighting at the date of the patent, the claim was too wide.

Mr. Justice BUTT asked whether it would be advantageous that he should try the other action between the same parties relating to the Cheeseborough patent. He said it was exceedingly inconvenient that a judge of the Probate Division, in which there are only two judges, should continue to sit outside his division, and the fortnight for which he was to sit had already expired.

Counsel on both sides agreed that though the Cheeseborough case was entirely different it was comparatively short, and much time would be saved by its being heard by a judge who had already acquired so much knowledge of electric lamps.

His LORDSHIP said he would consult with the President of the Division, and settle by Wednesday whether he could go on.

Mr. ASTON, Q.C., commenced his reply, which he continued on Wednesday till the Court rose at half-past 3. He proceeded to give the history of the various attempts that had been made prior to the date of Edison's patent to make a successful incandescent lamp by such men as Roberts, Scott, Harrison, Lane-Fox, Van Choate, and others, but without success, and pointed out that the first time the word "filament" was used was on the 1st of July, 1880, a year after Edison's patent was provisionally taken out. He then went on to prove that Edison, until the 17th of June, 1879, had not succeeded in re-introducing the discarded carbon, because up to that time it had not struck anybody that it was necessary, when they dealt with carbon, which was a most refractory material unless its properties were known, to give to it those properties which were possessed by metallic wires before they could solve the problem of getting an incandescent lamp. What was the property required to guard against the inconvenience arising from rigidity, the inconvenience arising from instability, and which always arose when at one time they had a cold temperature, and at another an intensely heated temperature, as was previously experienced? It was obtained by putting the carbon in a glass vessel connected with platinum wires in the form described by Edison. Carbon was readmitted after it had been rejected by Edison as late as the 17th June, 1879, as being the only medium which was suitable for the purpose intended, but in the particular form in which he used it. In other words he (Mr. Aston) contended that up to the date of Edison's patent carbon had been rejected by everybody as useless for the purpose, and was reintroduced by Edison to public notice in a particular form, and in the only form in which it was capable of being used, according to the evidence adduced before the Court. He asked his lordship whether it was not true that there were certain advantages new to this form of using the carbon which restored it to the favour of electricians after it had been rejected by them, and which entitled the plaintiffs to say that there had been an infringement in their patent. He next proceeded to quote a number of precedents which had a legal bearing on the present case, and said that the combination which was here claimed was a new combination. It was a new carbon conductor, which was put into a lamp new in form, new in character, and new in the advantages which it presented. It was true that Edison described in his specification the various modes of manufacturing his carbon filaments, but in his provisional specification, to which he was obliged to adhere, Edison did not make the manufacture of the carbon filament part of his invention. He contended that there was nothing which the patentee ought to have described in his complete specification of the 10th November, 1879, which had been omitted, or which invalidated the claim he now set up. The invention consisted of improvements in the lamp, not so much in improvements in the method of making the filaments for the lamp.

Mr. JUSTICE BUTT, in giving his judgment, said: The plaintiffs in this action complain of an infringement of the three patents relating to the construction of an electric incandescent lamp. The first of those is that of Mr. Edison, which I will describe later on. As I understand the matter the principal feature of Mr. Swan's patent is a process by which he proposed to make and maintain nearly a perfect vacuum in a globe. Mr. Ginningham's patent is one for fixing the carbon burner of an incandescent lamp to platinum wires. The defence consists of a denial of the validity of the patents, and a denial of the infringement. As to Mr. Swan's and Mr. Ginningham's patents, I intimated at an early stage of the proceedings that there was no evidence of such infringement, and I understand that that view has not been since seriously contested. The question, therefore, of validity of these two patents becomes for the present purpose immaterial. Now, with reference to Mr. Edison's patent, which is a patent of the 10th of May, 1880, there is one fact which is either admitted or beyond contest in this case, and

Digitized by Google

it is that before the date of the specification in question no good and efficient incandescent lamp was made or known. The invention which Mr. Edison claims has been compendiously stated by Sir Frederick Bramwell in his evidence, and he states it in these words. He is asked by Sir Richard Webster this question. "(Q.) Of course the construction of the specification is entirely for my lord, but would you suppose it was only for the purpose of pointing to previous knowledge that the combination you find described there is an electric machine or lamp? (A.) I find the vessel entirely made of glass, containing a carbon filament attached to the contact wires, which wires are sealed through the glass. I find that this vessel is to be exhausted of its air to a very great degree, the patentee mentioning that one millionth of the atmosphere may be attained. The patentee says that with a lamp of that construction light can be obtained by rendering the filament incandescent by means of an electric current." That is his account of the invention, and I adopt that account, and I adopt it without the slightest hesitation, because it is not a matter which depends on my own judgment. It was accepted by all the scientific witnesses called by the defendants. It was accepted in terms by Dr. Franklin, and the other gentlemen on the same side stated that they all agreed with his evidence. And that is the invention for the infringement of which these plaintiffs, who are owners of the legal and beneficial interest of this patent, 4,576, are now claiming an injunction and damages. As I have said, the defendants deny the validity of the patent; they also deny its infringement by them. I think it will be convenient to deal with the latter question first. I have all along been clearly of the opinion that there is no proof of an infringement of the claims Nos. 3 and 4 in Mr. Edison's specification. Those claims are as follows:—"No. 3. A coiled carbon filament or strip, arranged in such a manner that only a portion of such carbon conductor shall radiate the light, as set forth. No. 4. The method herein described for securing the platinum contact wires to the carbon filament, and carbonising the whole in a closed lamp, substantially as set forth." I now think, whatever may have struck me in parts of this inquiry, that there is no infringement of claim No. 1, and I shall be prepared so to hold if necessary. Claim No. 1 is in these words:—"An electric lamp for giving a light by incandescence, consisting of a carbon filament of high resistance, as set forth." But in the view I take of claim No. 2 this question becomes important. Now, the question of the infringement of claim No. 2 depends upon the meaning to be attached to the words in it, "a carbon filament." If these words mean a carbon filament made as described in the patent, I should hold that there was no proof of its infringement. But I do not so interpret these words. I hold them to mean any carbon filament, however made, which possesses certain qualities or properties mentioned in the specification, or necessarily resulting from the description there given. To answer that description the carbon filament must, I think, possess flexibility and resiliance. It must be of small cross section offering a high degree of resistance to the passage of an electric current, and it must present but a small surface from which radiation can take place. I am disposed also to think (but on this I refrain from giving a decided opinion) that the degree of resistance must not be less than 100 ohms, as mentioned on page 3 of the specification. Taking the above to be a correct interpretation of the words "a carbon filament" in Claim 2, it is clear that there has been an infringement of the patent by the defendants. Without stating the evidence of all the plaintiffs' witnesses it will suffice to read a part from that given by Mr. Rawson, one of the defendants. Now, in the course of his evidence Mr. Rawson states as follows:—"We have used carbon filaments connected at the ends with platinum wires in a vessel made wholly of glass; practically, the leading wires passing into and from the receiver are sealed into the body of the glass vessel, and the air is exhausted so as to get as good a vacuum as we can. We use that combination with the object of getting a good incandescent lamp, and in that incandescent lamp we use a carbon filament that is flexible, and as stable at high temperature as we can get it. We do not use Edison's process for the purpose of making a filament. What we do is in substitution of this process. Our process of making and preparing the carbon filament is superior to Edison's." That is his evidence, and, as I have said, the interpretation I have put, rightly or wrongly, upon the words "a carbon filament" in claim No. 2 shows that there is an infringement of the patent, applying that interpretation to it. But it is said, "even so, assuming the infringement, the defendants are not liable in this action, because the patent is invalid," and I will deal as well as I am able with the various arguments with which they maintain such to be the case. It is not always easy to separate in matters such as this that which the counsel have argued from that which some of their witnesses have said, and it may be in stating the objections I shall in one or two instances rather deal with the evidence of some of the witnesses than with the Solicitor-General's arguments. I am, of course, anxious not to put anything into his mouth which he did not express. At the same time there are one or two points in which I think the witnesses went beyond what he has argued. Of course, if he had given up the point expressly I should not refer to it. Now, the first reason, as I gather, in support of the invalidity of this patent is this:—It is said that a carbon filament, when taken to mean that which I have held it to mean, is a description too vague and indefinite—or, to use the Solicitor-General's words, too large. That is an argument to which I cannot accede, for I see no reason why a carbon filament having the properties mentioned in Mr. Edison's patent, in which the patentee tells the public how to make it, may not properly be the subject of a patent so that it is capable of being made by methods and of materials other than those set forth in the specification. This observation certainly does not lose any of its force when the question is not the thing patented, but only one of the several parts of a combination patent. Secondly, it is said (I am not professing to put the arguments in the order in which they were given) that the specification is not such as will enable a competent workman to make the lamp. The plaintiffs' witnesses have stated that in their opinion it would enable him to make the lamp. I use the word "lamp" for the moment apart from the question of a good lamp. We have had an expression of opinion from several of the plaintiffs' witnesses to that effect. I find that Dr. Odling, when he comes to be cross-examined on the subject, says what I am going to read: "Mr. Edison having first applied the filament conductor to an incandescent lamp, any competent electrician could make, by the description in Edison's patent, the carbonised filament there described. Geissler's vacuum tubes were perfectly well known in England. They were wires sealed through the glass. Sealing through the glass was a perfectly well-known operation to electricians. A competent electrician would want no other directions as to sealing the wires than Edison gives in his specification. A competent electrician would have no difficulty in properly exhausting the globe from Edison's specification." I take that as being very strongly in favour of what plaintiffs' witnesses have said, and I hold, therefore, that that evidence itself would be sufficient to warrant us in supposing that the specification in question is one which would enable a competent workman to make a good lamp. But, then, in the next place, if I understand it, it is said that a lamp made according to that specification would not be a good lamp. So say some certainly of the defendants' scientific witnesses. But there is evidence from the plaintiffs' witnesses to the contrary. And, moreover, the Solicitor-General expressly stated that he did not dispute the utility of Mr. Edison's invention. Under these circumstances I come to the conclusion that a sufficiently good lamp may be made by a competent workman from the description given in Edison's specification. It was said (and at one time I was strongly inclined to agree with the suggestion) by the Solicitor-General that the patent was invalid, because at the time of the final specification Mr. Edison himself knew of a better method of making a filament, and in support of that proposition his provisional specification of the 15th Dec., 1879, No. 5,127, was referred to. Now the date of that provisional specification, it will be observed, is subsequent to the date of the specification which we are now considering, which is the 10th of Nov. preceding. It was many months prior to the final specification we are considering, and therefore it is perfectly true to say that at the time of the final specification Mr. Edison knew of another mode of manufacturing his carbon filaments. The Solicitor-General said a better mode. Perhaps he is warranted in that. I am not prepared to deny it. Therefore the argument is, he ought to have disclosed it in his final specification, because a patentee is not entitled on the authorities, and as a matter of good sense he is not entitled, to withhold from the public a matter the discovery of which he was aware formed an important integral part of the provisional specification of his patent, and then take out another patent afterwards for that. What this would do would be to put the public, or those who deal with such matters, to the inconvenience and expense of taking out a licence to use two patents, whereas they ought to have the benefit of the whole by taking out a licence for one. It must, however, be borne in mind that Mr. Edison does not claim in his patent 4,576 for the manufacture of carbon filaments. His claim is for the union of carbon filaments possessing certain properties with other parts of his combination. There is no evidence that at the time of filing his provisional specification 4,576, he had discovered or knew of the process in patent No. 5,127, and I agree with Mr. Aston that an inventor has no right to put into his final specification as part of his invention a discovery which he had not made at the time, and of which he was ignorant when he filed his provisional specification. I think, therefore, the contention on this head cannot fall against the plaintiffs. But, further, it is alleged that the invention was not new, and this is a part of the case that has occupied the greater part of our time. It is perfectly true that a number of specifications anterior to Mr. Edison's patent have been adduced, describing either the separate parts of Mr. Edison's combination or something very like them. Without losing sight of the others, I refer specially to those of Mr. Lane-Fox, Mr. Pulvermacher, Mr. Sidot, and Mr. Swan. But no one of these publications, unless it be Swan's, contains the combination described in Mr. Edison's patent 4,576. That I am right in this I think must appear from the evidence generally. Well, now I will refer to the anticipations put before me. I do not propose to go through these publications in detail, but a good example of them, I think, may be found in the patent of Mr. Pulvermacher. It is said that that is a clear anticipation, at all events, of claim No. 3 of Mr. Edison's specification. It is perfectly correct to say that we have in Pulvermacher's specification a description of a carbon rod or thread which, if taken by itself, is very like Mr. Edison's coiled carbon filament mentioned in Claim 3, taken by itself. But it is used by Mr. Pulvermacher in a totally different way and for a totally different purpose. As I understand, Mr. Pulvermacher's specification was to be applied not to an incandescent lamp but to an arc light, the spiral in question was to be coiled round the inner core, also of carbon, there being insulation between the two. It was not to be attached to wires at both ends. Of course that would be inconsistent with the notion of an arc light. Curiously enough Mr. Pulvermacher's claim deals with two modes of lighting—the arc light and the incandescent light. It is very remarkable that, having described in detail this spiral rod or thread for the purpose of his arc light, when he comes to state what his mode of procuring an incandescent light is, he discards his carbon conductor altogether and resorts to metallic wires. Whatever likeness there may be between Mr. Pulvermacher's spiral rod and Mr. Edison's coiled carbon filament, mentioned in Claim 3, it is perfectly clear to my mind that Mr. Pulvermacher was wholly unaware that a coiled thread of carbon could be applied to the purposes of incandescent lighting, because if he was aware of it he would not discard it when he came to make his incandescent lamp, which is provided for in the very same patent. I am almost afraid to attempt another reference

Digitized by Google

to Dr. Odling's evidence, but I think that I have the passage under my eye. "Lamp E F 3 could not be made from Pulvermacher's patent, nor from anything known prior to Nov., 1879, except Mr. Swan's lamp, which would enable a competent electrician to make one." "But whence would he get the direction which would enable him to make the filament?" "I think I have got it from Pulvermacher's specification, but I find that is not so." "Anywhere else?" "I do not call to mind that there is. For Pulvermacher's purpose, the spiral must be of considerable size and thickness." So much for the alleged anticipation by Pulvermacher. With regard to Mr. Lane-Fox, I do not think it necessary to go at any length into a description of his proposed lamps or systems of lighting. It seems to me that the Solicitor-General was perfectly warranted when he said it was quite clear the different specifications of Mr. Lane-Fox that he had realised and knew all the elements that were necessary to make a good incandescent lamp. I will illustrate what I mean by one example—the necessity of a high degree of resistance. I think these observations were perfectly warranted, and it is true that as I have followed them when he comes to prescribe what he would use for the purpose of his own invention, Mr. Lane-Fox nearly always seems to revert to a metallic wire for a conductor, and not to a carbon thread. He does mention in one of his specifications a carbon conductor; but then, as I understand the matter, when he comes practically and finally to deal with the subject he disclaims it, and it drops out of his patent, evidently because he did not know how to make an efficient carbon conductor. He says it was less desirable than the metal under all circumstances, and he did not know how to make one which would be better. I now come to the alleged anticipation by Mr. Swan, and it seems to me that his lamp is the only combination at all like that of Mr. Edison. Other inventors, other men of science, may have described individual parts of the combination, but none of them have brought these parts into combination as Mr. Edison has done. I think it is clear that each individual part of the combination may have been known before, yet if the combination of those parts be new, that combination may very properly be the subject of a patent. But it does appear to me that if Mr. Swan's conductor was practically the same thing as Mr. Edison's carbon filament, then we have in Mr. Swan's lamp and in Mr. Swan's lectures, I think, the whole of Mr. Edison's combination, and that before the date of Mr. Edison's specification. The main question, therefore, is:—Are Mr. Swan's carbon rod or pencil and Mr. Edison's carbon filament the same thing? Now, I think they are not. It is a question of interpretation, and *primâ facie* no doubt the meaning of the words in a written contract is for the judge, but where technical terms, words of art, are used, the evidence of scientific witnesses and experts to explain the sense in which they are used in their opinion may be received. Accordingly each side has called a certain number of scientific witnesses, to whom have been put questions as to the meaning of the words "a carbon filament" in claim No. 2. It is said that in the multitude of counsellors there is wisdom, but when those counsellors turn out to be equally divided in opinion, and when it turns out that the only point on which they agree is that they agree to differ, I do not see how the judge derives very much benefit or advantage from their evidence. In fact, such is the case here. The witnesses on behalf of the plaintiffs say in effect that Mr. Swan's carbon rod or pencil is not only different from Mr. Edison's carbon filament mentioned in Claim 2, but it is totally and wholly different. The defendants' witnesses say, "In our opinion these two things are identically the same." Well, in these circumstances I must draw such conclusions on the point as my own uninstructed mind will enable me to arrive at. To my mind it does seem that a carbon pencil or rod is a very different thing from a carbon filament. It is difficult to express exactly the whole process of reasoning by which I come to that conclusion, but it seems to me to carry one a long way on the road to that conclusion, to say that a rod or pencil is a rod or pencil, and a thread is a thread. There are, however, certain differences which are not difficult to explain, it appears to me. It seems clear that one of those differences between Mr. Swan's conductor and Mr. Edison's conductor is this: Mr. Edison's conductor possesses smallness of cross-section, combined with other properties which Mr. Swan's does not. Mr. Edison's conductor possesses a degree of flexibility which, to my mind, is not even approached by Mr. Swan's, and I think I am again confirmed in this view by some of the evidence given by Dr. Odling. "Except in Swan's," he says, "I cannot point to anything in this specification in which only this rod or stick of carbon alone is described, even in the lamp of Swan produced. In the lamp that Swan produced the conductor is a rod." To show what he meant, he says, in effect: "True, it is a rod, but it is a filament also, and I refer to Mr. Swan's subsequent communication the 1st of January, 1882, in which he calls his conductor a filament." But then, as you know, as a matter of anticipation, that broke short in Dr. Odling's hands, because instead of its being in anticipation it is about 12 months after the event. He goes on to say, "As applied to a conductor exclusively of carbon, I cannot point out any anticipation of Edison's statement contained in the passage from line 23 to line 43 on page 3 of the specification." The statement to which he referred begins with the words, "heretofore lighting by incandescence," and ends with the words, "high temperature." Now, I cannot help thinking that if Mr. Swan at the time in question, not in January, 1880, but at an earlier period, before Edison's specification—had Mr. Swan known of the various advantages of Edison's carbon filament as used, his lamp would never have contained a straight rod fixed at each end. By straight of course I mean lying even between the two points of junction. That straight rod was fixed to the end of platinum wires. Moreover, I think there is no evidence to show that before Mr. Edison's specification he knew how to make a carbon conductor of anything like so small a cross section which would answer the other requirements stated. The first time I can find Mr. Swan's conductor spoken of by him as a filament is in his final specification of the patent which forms one of the subjects of this suit, and that is under date of the 1st of July, 1880, Mr. Edison's final specification being some seven or eight weeks prior to that date. What he really wanted was unknown to him; but, at all events, if he had chosen to take advantage of the knowledge conveyed to the public by Mr. Edison's specification, he could have done so; but you do find it is true that Mr. Swan some weeks later is found calling his carbon conductor a filament. A rose does not smell the sweeter for being called a rose, and the fact that Mr. Swan did subsequently call that rod a filament does not at all convince me that it was properly so called. I do not forget that it is also in evidence on the part of one or two witnesses, Dr. Odling among the number, that electricians have adopted the word filament, and, as I understood him, it is applied to all manner and kinds of carbon conductors in these incandescent lamps. Well, that may be so. Words often become when applied to particular trades or sciences twisted from their original meaning. "A dozen" at one time meant twelve, but I am not quite clear that it has not been held to be in particular trades something different. It certainly in many does not mean twelve or anything like twelve. An illustration was shown when there was a very beautiful flower—a tulip—produced, and that portion of it which holds and supports the anther was referred to as a filament. I was told that in botany that was universally recognised as a filament, whatever size it might be. It has acquired that name in botany, just as these conductors amongst electricians have since acquired the name filaments. But I suspect they have received that designation since flexibility was introduced and rigidity was tabooed. I have, therefore, come to the conclusion, firstly, that there is no sufficient reason for saying that this patent is invalid on any of the grounds suggested on the part of the defendants; amongst others, of course, that there is no ground for the assertion that it has been anticipated, or, in other words, that it is not new. In the next place, I hold in Claim No. 2 that there has been a clear infringement by the defendants in their lamp. That being so, the decree I must give is that those of the plaintiffs who possess the legal beneficial interests—who are assignees—of Mr. Edison's patent are entitled to the verdict. With regard to the other plaintiffs, the action must be withdrawn or dismissed.

Mr. ASTON intimated that the action had been dismissed. He then asked for costs to be allowed on the higher scale, and that the lamps of the defendants should be handed over to the plaintiffs or destroyed.

Mr. CHARLES applied for a suspension of the injunction; but

Sir RICHARD WEBSTER pointed out that where a final judgment has been given in favour of the plaintiffs the injunction followed as a matter of course, otherwise it would stultify the decision of the judge.

Oswald v. the Maxim-Weston Electric Light Company (Limited).

This case came on for hearing in the Lord Mayor's Court, Guildhall, before the Recorder (Sir T. Chambers, Q.C.) and a jury, on Monday. The plaintiff, Mr. E. H. Oswald, sued to recover the sum of £35. 6s. 6d., being commission at the rate of 25 per cent. on £141. 7s. 3d. paid to the defendants for the supply of electric lamps and light at Covent Garden Theatre. The defendants pleaded that they never were indebted, and also that they had satisfied the plaintiff's claim before action was brought. Mr. Pollock, counsel for the plaintiff, said that an agreement was entered into between the plaintiff and Mr. Hugh Watt, M.P., managing director of the defendant company, by which plaintiff was to have 25 per cent. on an order which was obtained by the plaintiff for the lighting of Covent Garden Theatre for eight weeks during the Promenade Concert season, 1884. The defendants contracted to supply twenty arc lamps, but it was afterwards discovered that these would not be sufficient, and seven more were put up. The Covent Garden people paid the amount of the contract for the twenty lamps, but declined to pay for the extra seven, and the defendants sued them for the amount, which was £141. 7s. 3d., and recovered judgment. The plaintiff had been paid 25 per cent. commission on the total amount received for the twenty lamps, and he now claimed 25 per cent. on the £141. 7s. 3d. which had been so recovered. Mr. Lewis Glyn, for the defendants, said he might say at once, to save time, that the defendants declined to pay because they contended that they could not go on paying commission after the first order. The defendants contended that the supply of the extra lamps was in law nothing at all to do with the first lamps under the contract. The defendants might as well be expected to go on paying commission for a hundred years, or for any length of time if any work was done after the first order. The plaintiff had had 25 per cent. on the price paid for the first twenty lamps, and he (the learned counsel) thought that was quite enough. Mr. Pollock pointed out that the agreement between the plaintiff and the defendant was for commission on "lighting" the Covent Garden Theatre. The learned judge said he would not stop the case at present. The plaintiff, in his evidence, spoke to other transactions which he had had with Mr. Watt, who arranged to pay him 10 per cent. commission on all orders which he introduced from the country. When he spoke about procuring the order for supplying Covent Garden Theatre, plaintiff said he could not accept 10 per cent. commission. He must have 25 per cent. This was agreed to, and the agreement was put into writing. In any case he was entitled to 10 per cent. in consequence of the arrangement which had been come to with respect to all business introduced by the plaintiff to the defendant. For the defence, Mr. Hugh Watt, M.P., was called, and said he never had any transaction with the plaintiff previous to the one which was the subject of the present action. The plaintiff had asked to be appointed agent of the company at Nottingham. Witness went down there and made inquiries, but he did not appoint the plaintiff to the agency. Witness had never promised or agreed to pay the plaintiff 10 per cent. on any orders introduced. When the arrangement

PRESE LIBRARY UNIVERSITY CALIFORNIA
Digitized by Google

was made in writing to pay the plaintiff 25 per cent. the plaintiff verbally undertook to return a third of the commission. By some mistake the plaintiff had been paid £8 too much. The learned judge, in directing the jury, said that upon the terms of the agreement the plaintiff could not recover 25 per cent. upon the extra work. It would, however, be a question for the jury whether there had been a previous verbal arrangement to pay the plaintiff 10 per cent. upon all work introduced. The jury found for the plaintiff for 10 per cent, the exact amount to be ascertained by the registrar of the court.

**** *Owing to the length of our "Legal Intelligence," we are compelled to leave over to our next issue the interesting report to the Balloon Society by Mr. Alfred Thompson on "Electricity as a Safeguard against Fire," &c.*

COMPANIES' MEETINGS & REPORTS.

Oriental Telephone Company.

An extraordinary general meeting of the members of this Company was held on the 13th inst. at the offices, 14, Austin Friars, under the presidency of Mr. W. Addison.

The CHAIRMAN proposed a resolution confirming as special resolutions the resolutions passed at the extraordinary meeting held on the 20th ult. They were for making certain alterations and additions in clauses 56, 60, 61, and 64 of the Articles of Association of the Company, the object sought, as stated by the solicitor at the last meeting, being to withdraw from the Directors certain powers which it was thought were too wide for them to exercise without the shareholders' consent.

Mr. T. LLOYD seconded the motion, which was adopted.

West India and Panama Telegraph Company (Limited).

Report of the Directors, to be presented at the eighteenth ordinary general meeting of members, to be held at the City Terminus Hotel, Cannon-street, on Thursday, the 27th inst., at 12 o'clock.

The Directors submit the accounts for the six months ending 31st December, 1885. The amount to credit of revenue is £38,008. 18s. 7d., and the expenses have been £23,191. 2s. 1d., leaving a balance of £14,817. 16s. 6d., which, with the balance of £1,920. 5s. 9d., brought from last account, makes a total of £16,738. 2s. 3d. Of this sum the Directors have placed £2,000 to reserve, leaving an available balance of £14,738. 2s. 3d., with which it is proposed to deal as follows :—

Payment of 6s. per share on account of arrears of dividend on the First Preference Shares.....	£10,368	18	0
Balance to current half-year's account.....	4,369	4	3
	£14,738	2	3

The traffic receipts for the half year show a decrease of £2,176. 8s. 11d. on those of the corresponding period of 1884. This decrease can only be attributed to the commercial depression which is affecting the West Indies, perhaps, even more severely than other parts of the world. The Company's ss. "Grappler," referred to in the last report as being on her way home, after a thorough overhaul in the Thames, returned to the West Indies with 250 knots of cable on board, and the Directors have great satisfaction in adding that she has since repaired the original Cuba-Jamaica section with an expenditure of 71 knots, thus duplicating a most important section of the Company's system. The duplicate Jamaica-Porto Rico cable, which, it will be remembered, was restored on the 24th October, 1884, again became interrupted on the 28th November last. The "Grappler," when on her way to repair the Cuba-Jamaica section was ordered to examine the locality of this interruption. The break was found to be in about 2,400 fathoms of water, and the repair will require the expenditure of a considerable length of new cable, as no workable depth was found along the course of this line in the vicinity of the interruption. The cable must therefore be recovered at the nearest practicable points on each side of the break, and a new length laid in between those points. As far as soundings hitherto obtained enable an opinion to be formed, some 160 knots of cable will be required to complete the connection. The Trinidad-Demerara section has been again interrupted, and as, notwithstanding costly repairs, it has not worked satisfactorily for some years, proposals have been made to the colony of British Guiana for laying a new cable. The length that may be required for this renewal will be over 300 knots. If the Company's proposals are accepted, the cost of this new cable as well as that of the Cuba-Jamaica and Jamaica-Porto Rico repairs already referred to, will cause heavy draughts on the reserve fund. Several breaks in the cables occurred during the half-year under report and have been repaired. All stations are now in telegraphic communication. The shareholders were doubtless as much surprised as were the Directors by the appearance in November last of an advertisement under the authority of the Postmaster-General announcing that Her Majesty's Government were prepared to recommend Parliament to grant a subsidy for the construction and working of a submarine cable from Halifax (Nova Scotia) to Jamaica, *vid* Bermuda, and calling for tenders for the same. The proposed line is part of a scheme that was before the Government in 1882, when, being adversely reported upon by the late Mr. Fawcett, the Postmaster-General at the time, it was rejected. Among the grounds of Mr. Fawcett's objections were the physical difficulties of the route between Bermuda and the West Indies, which passes over the greatest known depths in the world, and the evident injustice to the West India and Panama Telegraph Company which a State-subsidised competition would involve. Mr. Fawcett's objections were apparently so fatal to the scheme, and so novel is the project of using the national resources to compete with a system the establishment of which had received the cordial encouragement of the colonies and the approval of the Home Government, that the Directors little expected to hear of it again, and they thought themselves justified in this belief by the facts that Jamaica is already connected with the nearest telegraph system by three of this Company's cables, that it has been in telegraphic communication with England for the last 15 years, and that the volume of the whole West Indian telegraphic business is not sufficient to employ a single line of cable for more than about five hours a day. In these circumstances they could not imagine that Her Majesty's Treasury, which had invariably refused every application from this Company for assistance in its efforts to continue the unremunerative telegraph service of the West Indian Colonies, would sanction the payment of a subsidy for an unnecessary fourth cable, whose competition for the poor traffic of the region would seriously impair the power of this Company to maintain the West Indian system. The views of the Directors on the proposal were communicated to the proper authorities. It is now six months since the appearance of the advertisement, and nothing has since been heard of the scheme. It is hoped, therefore, that it will be allowed to drop, and that this Company will not have—to use Mr. Fawcett's words—"just cause for complaint against Her Majesty's Government if it were now to subsidise a rival company." In accordance with the Articles of Association, Henry Holmes, Esq., and Henry Weaver, Esq., retire at this meeting and offer themselves for re-election. John George Griffiths, Esq., the auditor, also retires and offers himself for re-election.

BUSINESS NOTICE.—We understand that Messrs. Ganz and Co., of Buda Pesth, manufacturers of Déry, Blathy, and Zipernowsky's secondary transformers, have opened an office in No. 4, Westminster-chambers, Westminster, with the view of undertaking electric light installations in this country.

NOTES.

THE STEAMSHIP "AGNES."—We understand that this vessel, belonging to the Eastern Extension Company, arrived home on Friday last, and is now in the South-West India Dock.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 21st inst. were £2,368, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE TELEGRAPH IN CHINA.—The Chinese Government have, it is said, in contemplation to extend telegraphic communication from Wuchang, on the Yangtze river, to the city of Yunnan, in the Yunnan Province. The line is expected to be open by the end of the present year.

RAILWAY CONTRACTS.—Messrs. Blakey, Emmott, and Company have again secured nearly the whole of the London and North Western Railway Company's contract for electrical apparatus and cotton-covered wire. They have also obtained a portion of the Manchester, Sheffield, and Lincolnshire, and Lancashire and Yorkshire Railways' contracts.

LIGHTHOUSE AT ROUND ISLAND.—The foundation stone of this lighthouse, to the north of the Scilly group, has been laid by Lady Douglass, wife of Sir James Douglass, chief engineer of Trinity House, London. The building of this structure will be under the superintendence of Mr. W. T. Douglass, resident engineer of the works now being executed at the Bishop Lighthouse.

RESISTANCE OF COPPER.—Some experiments, carried out by Sigmund von Wroblewski, upon the resistance of copper at very low temperatures, show that there is no permanent alteration in the resistance due to extreme cold, and that the electrical resistance diminishes at a greater rate than the temperature, leading to the conclusion that resistance vanishes before absolute zero can be reached.

FRENCH AND ENGLISH TELEGRAPHS.—The President of the Chamber of Commerce has made an application to M. Granet, Minister of Posts and Telegraphs, to establish direct telegraphic communication between Havre and Liverpool. M. Granet replied that the telegraph system between England and France was regulated by treaties between the two countries, but these treaties might be modified on their expiration.

ELECTRICITY AND WHISKY.—According to the *Albany Sunday Press*, the ripening of spirits by electricity is now effected on the other side of the Atlantic. Three incandescent lamps of 32 candle-power are inserted in a barrel of whisky, and their light and heat are said to produce the same effect on the spirit as the ripening of age, thus fitting the whisky for market in a very short time. Good judges report that the process improves the quality of the spirit.

ELECTRIC TRAMWAY.—The success which has attended the working of the electric tramway at Blackpool, which has been fully described in previous numbers of *The Electrician*, is an unequivocal answer to those who doubted the practicability of applying electricity to this means of locomotion. That the tramway in question in three consecutive days recently carried 15,000 passengers over a line two miles long without any hitch or delay is an eloquent testimony to the rapid development of electrical science and its future possibilities in the direction of practical mechanics.

ROYAL SOCIETY.—At the recent *soirée* of the Royal Society, among other electrical apparatus Messrs. de la Rue and Hugo Müller showed how the chloride of silver battery could be applied to electric lighting by a quantity arrangement. Instead of using a solution of chloride of ammonium simply, the solution, containing 2½ per cent. salt, is converted into a vegetable jelly, by dissolving in it Ceylon moss (Agar-Agar) to make a stiff jelly; this supports the zinc. The chloride of silver in powder is spread evenly on the bottom of the dish on which a piece of silver foil is placed.

ELECTRIC COMMUNICATION WITH LIGHTSHIPS.—An influential meeting was recently held at Ramsgate to promote electric communication between lightships and the mainland. Colonel King-Harman, M.P., was among the speakers, and promised to do all in his power to get the Government to take active steps in the matter. The following resolution was passed:—"That this meeting, being of opinion that it is desirable to promote the movement for establishing electric communication between lightships and shore, a deputation wait on the Board of Trade to impress on them the importance of the subject."

AN ELECTRICAL "STOP."—A German *savant* who had long been suffering from the everlasting pianoforte playing next door has devised the following method of putting a stop to it at pleasure:—An electric battery was connected with a powerful electro-magnet. Whenever a stream of electricity was turned on its effect could easily be felt through the wall by the horizontal steel strings in the piano, which is instantly put out of tune. Whenever the electric stream was stopped, which occurred as often as the victim of the piano plague went out, the mystical influence stopped, and Miss Else, the offending pianist, could play.

ELECTRICITY IN MILAN.—The electric light is very popular in Milan. The electric light company doing business there is constantly receiving fresh orders for installations to be put up in various parts of the city. The company had in operation on the 1st of January, 1885, 5,300 incandescent lamps, and exactly a year later the number had increased to 7,177, in addition to 66 arc lights, while by the end of March last these numbers had been increased by 846 incandescent and 13 arc lamps. Since then further additions have been made, and the company expect to present a handsome balance-sheet at the end of the year.

THE GERMAN ZINC INDUSTRY.—All zinc works are at present busily engaged on consignments for foreign customers. By reason of the long winter and the interruption to navigation, the stocks on foreign account have accumulated both in Westphalia and Upper Silesia, but the deferred orders are now being rapidly discharged. As compared with last year, however, both in Rhineland-Westphalia and Silesia, the stocks have considerably fallen off, April 1st showing a decrease of 4,300 tons. It is said that tin has been found in Dakota, in North America. How this will affect the zinc industry remains to be seen.

DRIVING COUNTER-SHAFTING BY DUPLICATE ENGINES.—The usual method of driving counter-shafting by duplicate engines has made it necessary to employ fast and loose pulleys or clutch gearing on the shafting and a wide fly-wheel on the engines. There has also been much difficulty with these arrangements in getting the second engine to the speed of the engine it is desired to relieve, and in shifting the straps, but we now learn that a new method has been devised by Mr. W. W. Beaumont, M.I.C.E., of driving in such a manner that only one pulley opposite each engine is necessary, and it is only necessary to start one engine to liberate the other.

THE TELEPHONE IN THE MALAY ARCHIPELAGO.—Complete systems of telephone lines have recently been completed at Lingha and Rhion for the Sultans of these islands At Lingha

Digitized by Google

seven miles of line have been erected and five stations, all of which are in connection with each other. At Rhion there are four stations. Lingha is an island 150 miles from Singapore, and Rhion about 50 miles from the same place, both in the Malay Archipelago. Gower-Bell telephones have been used. These are the first lines (either telephonic or telegraphic) erected in these islands, and they are reported to work admirably. The work has been ably done by Mr. J. B. Saunders, of the Oriental Telephone Company's staff.

THE ELECTRIC LIGHT IN SPAIN.—In continuation of our former remarks upon the proposed installation of the electric light in Madrid for public use by merchants and others who have quarrelled with the gas company, and who are in the meanwhile using oil, we learn from the Spanish paper *El Dia*, of Monday last, May 24th, just to hand, that Messrs. Edison's agent, who recently arrived in Madrid, has left by express train for Paris, in order to lay before the representatives of the Edison Company in Paris the plans of the proposed installation. Madrid advices also state that experiments were to be made this week in the Mercantile Club of two systems of electric lighting, one by a Paris house and the other by a Marseilles firm.

DIAMAGNETISM OF QUARTZ CRYSTAL.—Hitherto no substance among those that exhibit diamagnetic properties has been observed to possess any permanent diamagnetic polarity analogous to the permanent paramagnetic polarity of hard steel. The property of retention of diamagnetisation is, however, found by Dr. O. Tumlirz, of Prague, to be possessed by rock crystal. Both those specimens that show right-handed and left-handed optical properties are alike in this respect, and the axis of diamagnetisation appears to be independent of the crystallographic axis, and dependent only on the axis of initial magnetisation. Dr. Tumlirz, whose investigation is published in *Wiedemann's Annalen*, appears to think that these facts negative Becquerel's theory of diamagnetism.

RUNNING A STAMP MILL BY ELECTRICITY.—It is reported from New Zealand that a Dunedin electrical engineering firm is carrying out a contract for the transmission of power to run a stamping battery of twenty heads. The scene of operations is a gold mine in the mountainous country some thirty miles beyond Lake Waktipu, and the power to run the battery is transmitted from a waterfall in the neighbouring valley, straight over a mountain of about 2,000ft. in height, and for a distance of about two miles. The conducting wire is of the same size as an ordinary telegraph wire, but of copper, and is suspended from telegraph insulators in the usual manner. No doubt there are many places in this country where power could be provided most economically from water-powers and dynamo machines, as in the above case. We shall be pleased to hear from any mills so situated.

E.M.F. OF VOLTAIC ARC.—Von Lang's direct measurement of the E.M.F. of the voltaic arc is thus described in the *Journal de Physique*:—Two arc lamps are placed symmetrically in the circuit of a strong Bunsen battery. The middle A of the battery and the middle B of the conductor which unite the two lamps are at the same potential. The resistances of the two portions of the circuit which go from A to B are evaluated by means of a Wheatstone bridge; first, when the two lamps are in operation; second, when the carbons have been replaced by resistances which bring down the current to its former value. Half the difference of the two numbers obtained gives the resistance, which is balanced by the negative E.M.F. of one of the voltaic arcs. This E.M.F. is calculated by multiplying the difference obtained by the intensity of current. Thus the author obtains the value 38·6 volts.

"THE TIMES" AND THE PHONOPORE.—Mr. C. Langdon Davies, who is the inventor of something which he calls a phonopore, cannot be congratulated on having enlisted *The Times* as an exponent of his invention. Whenever the leading newspaper takes a scientific matter in hand the result is almost invariably disastrous either to its client or the investing public. We know nothing about the phonopore; but we do know that the account of it which appeared in yesterday's *Times* is absurdly unscientific. If Mr. Davies has discovered anything that will pass muster under competent inspection he should go to a scientific or technical journal. And on the other hand, we consider that *The Times* has no business to publish matter of this kind, which may delude the speculating world, without first assuring itself of the sanction and countenance of judges more impartial than any inventor is ever likely to be.

ELECTROLYSIS OF SOME CHEMICAL COMPOUNDS.—M. D. Tommasi, according to an abstract in the *Journal* of the Chemical Society, maintains that if an aqueous solution of potassium chlorate acidified with sulphuric acid so diluted that when treated with metallic zinc no reduction of the chlorate takes place is submitted to electrolysis, the anode being formed of pure zinc, reduction occurs and potassium chloride is formed, although if the electrolysis is conducted with platinum electrodes no such action takes place. The reduction is therefore due to the direct union of the zinc with the oxygen of the chlorate, and not to the action of nascent hydrogen. Potassium perchlorate is not reduced by electrolysis, even when a zinc electrode is employed. A dilute aqueous solution of chloral hydrate in a porous cell placed in a vessel of water acidified with sulphuric acid was electrolysed, the cathode being placed in the chloral and the anode in the water; chlorine and free hydrogen were given off at the cathode, and aldehyde was formed.

THE BROADWAY ARCADE RAILWAY.—A Street Railway Bill which has just passed the New York State Legislature and has received the approval of the Governor introduces a feature into street railway construction that may be fraught with excellent results. The Bill is known as the Broadway Arcade Railway Bill, and, as its name implies, it provides for the construction of an electrical railway the entire length of Broadway, New York. It is also to be an underground railway, but not in the sense of the London underground railway. In short, instead of being, as our Metropolitan is, a tunnel, it will be an arcade—Broadway will practically be scooped out to a sufficient depth to allow of another street below the present one, with two lines of shops, footways, and railway lines. But these features do not exhaust all the conveniences that will be effected by the proposed construction. The space underneath the footway on either side of the arcade will be utilised for the water and gas mains, and for the telegraph and telephone wires; and hence the necessity of breaking up the road or pathway whenever it is necessary to do anything with gas or water pipes, or with telegraph wires, will be obviated.

PREPARATION OF METALS FOR NICKELISING.—Surfaces to be nickelised are usually polished before being submitted to the action of the bath. After this operation is finished they remain covered with a slight greasiness, which is often still further increased by contact with the hands. This is one of the principal causes of failure to obtain a perfect nickelisation, and it is therefore essential to have the surfaces as clean as possible. The *Elektrotechnische Rundschau* says that the following process will always yield good results:—Prepare a hot solution of one part by weight of potash in ten of water, and place the object in this and allow it

Digitized by Google

to remain therein for one or two minutes, and then wash with plenty of water. Next put it into a bath made by slacking quicklime in water and adding enough water to make the mixture look like milk. Then wash again with fresh water. Finally, place the object in a solution of one drachm of hydrochloric acid to a quart of water, and wash a third time with pure water. The surfaces will now be well adapted for receiving a nickel coating, and the only precaution to take is to prevent them from coming into contact with the hands or other greasy bodies.

TELEGRAPH WIRES AT BELFAST. — The Belfast Main Drainage Bill, as amended in the House of Commons, contains the following in relation to telegraph wires:—"Fixing, placing, or attaching wires, tubes, or other apparatus across, over, or along, but not under, any public street for telegraphic, telephonic, or any electrical purpose. Section 55 provides that no such apparatus shall be fixed, placed, or attached as to cross over or pass along any public street except with the previous license, in writing, of the Corporation, under the hand of the Town Clerk, which license shall not be unreasonably refused, and subject to such terms and conditions as they may from time to time prescribe, so as to prevent danger, annoyance, or obstruction to passengers or traffic passing over or along, or being in or upon, such street. Any person offending against this enactment, or who fails to observe and perform any of such terms and conditions, shall be liable for each offence to a penalty not exceeding £10, and to a daily penalty not exceeding 40s. for every day the offence shall continue after notice, in writing, under the hand of the Town Clerk, of the breach of the enactment, and the Corporation may cause such apparatus to be removed and altered, and may recover the expense of and incidental thereto in any court of competent jurisdiction."

AURORA BOREALIS.—A note of the Abbé Maze to the *Academie des Sciences* says that an Aurora Borealis was observed by him at Rolleville (Seine Inferieure) on the 30th March, thus coinciding with the magnetic disturbance reported by M. Mascart. He says that about nine o'clock in the evening of Tuesday, the 30th March, at Rolleville (latitude 49° 54′ 52″; longitude 2° 7′ 27″ west), he perceived a great brightness in the north direction. It was a white and vibrating light. This last character made him think it was an Aurora. Nevertheless he could not recognise any of the characters which he had observed at other times. There was no colouration, except towards the zenith a slightly reddish tint, something like the greyish red which one observes between the two red bands of the double rainbow. He did not observe either any of those jets which sometimes dart in the sky. A great black stratiform cloud which was on the horizon prevented him from determining with precision the exact place of the centre of action of the Aurora; but, as far as he could tell, it was in the magnetic meridian. He was a good judge on this point, since he had spent the day in determining the meridian of the place. At ten o'clock the phenomenon still continued; at eleven the sky had become so covered with clouds that no observation was possible. The next evening the north horizon appeared rather brighter than it should be, but there seemed none of the special characters of an Aurora.

THE INSTITUTE OF CIVIL ENGINEERS.—The annual general meeting of the Institute was held on Tuesday, May 25, Sir Frederick Bramwell, F.R.S., occupying the chair. As fifty years had elapsed since a connected account had been given of the origin and progress of the Institution, it was thought not inopportune to submit a condensed narrative of the successive steps by which its present position had been arrived at. This historical notice stated that the Royal Charter of Incorporation was granted in 1828, and went on to describe the qualifications of members and associates, and the modifications which had taken place at various times since. It was also shown that various modifications had been made in the composition of the governing body, and that in 1844 an alteration was made which had materially influenced the future of the Institute. This was the change in the duration of the Presidentship, which had up to that time been practically a permanent appointment. Up to 1880 the president seems to have been elected for a period of two years, or rather elected for one year, and reappointed the second. Since 1880 there has been an understanding that the president should hold office for one year only. The present secretary has held office for thirty years, and if we may interpolate an opinion, we should say that it is due to his labours that the Institute is at the present moment so flourishing, and especially that the publications of the Institute are so valuable. In 1836 there were on the register 146 members, 100 associates (many of whom were afterwards transferred to the class of members) and 14 honorary members—together 254.

TAUNTON.—On May 1st the Thomson-Houston system of electric lighting was successfully inaugurated in Taunton. This is the first provincial town in England that has adopted the system, although it has been largely used in the States. The initiative in this work has been taken by Mr. Massingham, who, after careful investigation of the various systems in use at the Kensington Exhibition last year, selected the Thomson-Houston system for trial, and attempted to float a local company for Taunton. In this he failed, but, undismayed, determined himself to undertake the work, and arranged with Messrs. Laing, Wharton, and Down, the representatives for the system in England, to install a thirty-light machine with the necessary lamps. The power is obtained from a horizontal steam engine with locomotive boiler by Messrs. Easton and Waldegrave. The engine is fitted with a Pickering governor. The light has been pretty extensively adopted by the principal tradesmen of the town, and we are given to understand that so much is the light appreciated that a further extension of the plant will very soon be rendered necessary. In one or two cases Edison-Swan lamps are used for the lighting of interiors instead of arc lamps. A grant from the Town Council and the Taunton Market Trustees, supplemented by private subscription, found the necessary funds for the erection of the masts and circuit for the lighting of the parade, where there are seven arc lights; but the cost of the maintenance of these lights is defrayed by Mr. Massingham till the end of the year, when it is hoped the authorities will, seeing the manner in which the light is appreciated, take the cost of maintenance off his hands upon themselves. Messrs. Laing, Wharton and Down and Mr. Massingham are to be congratulated upon the success of their enterprise.

SUBMARINE TELEGRAPH CLERKS' LIBRARY.—On the evening of Friday (says the *City Press*) the annual general meeting of the subscribers to the Submarine Telegraph Clerks' Library was held at the Talbot, London-wall, Mr. T. Sharkey (chairman of the committee) presiding. The balance-sheet, though dealing with no large amount, was perfectly satisfactory, showing, as it did, a small sum on the right side. The library was established in 1877 for the use of the clerks in the transmission department of the above company, and has steadily progressed until it now consists of some 1,200 volumes pretty equally divided into light and thoughtful literature. A great deal of the credit for so much success is due to the hardworking and courteous honorary secretary, Mr. T. P. Mullane, and advantage was taken of the meeting to testify the appreciation of the members of those

Digitized by Google

qualities by presenting him with a gold watch suitably inscribed, and an illuminated address. The presentation was made by the chairman, who, in a few graceful words, expressed the esteem and honour in which Mr. Mullane was held by those who knew him. Not only as honorary secretary had Mr. Mullane served the subscribers, but to him was due the first inception of a library, and to him they owed many a pleasant hour by their "ain firside." The honorary secretary found it very difficult to reply. As a rule, when testimonials are about one of the first to know of it is the recipient; but in this case the committee had worked so efficiently and so quietly, and had met with such ready sympathy that nothing of their intention had leaked out. Mr. Mullane managed to utter a few words of thanks, comparing his astonishment to the result of a thunder-bolt from a clear sky. His thanks were cut short, however, by a rousing "He's a jolly good fellow," and the meeting resolved itself into a musical party, presided over by Mr. Killick.

Folkestone Exhibition.—The electric lighting of the Exhibition has been entrusted to the Electrical Power Storage Company, and is one of the most interesting features of the Exhibition. The whole installation has been designed by the engineers of the company as a perfect model of a large electric lighting station, such as would be required for the lighting of a town, and both arc and incandescent systems are represented. The arrangements made enable the different groups of arc lamps to be turned on and off at will without the remaining lamps being in any way affected, and by means of the E.P.S. accumulators a total extinction of the incandescent lamps is rendered practically impossible. As a further safeguard, the whole plant has been sub-divided, and each of the galleries and other departments is supplied from two separate and distinct circuits. Two sets of batteries in glass boxes and of the newest type, containing thirty-one plates in each box, will be charged in the day time, and kept as a reserve. There are in all thirty-six arc lamps, each giving a light of 3,000 candles, and 1,250 incandescents, of ten candle-power. The arc lamps are fixed outside for the lighting of the gardens and entrance to the Exhibition, and are also suspended from the roof in the central nave, which will be very brilliantly illuminated at night. The power is supplied from two Marshall engines, each giving eighty horse-power, this being transmitted by means of countershafts to four Crompton dynamos, which supply all the current for both arc and incandescent lamps. There has, up to the present, been no public exhibition for lighting which has been so carefully worked out in all its details, and electricians will doubtless find much of the apparatus well worthy of their inspection. The whole of the electric light machinery and appliances for the generation of the current are contained in a building separate from the galleries of the Exhibition, being connected only by a covered way for the convenience of visitors who may desire to inspect them. This also applies to the refreshment rooms of Messrs. Spiers and Pond, for whom a similar covered way has been provided.

Edinburgh Exhibition.—An exhibit in Court 21 shows a regimental field telegraph, designed for the Queen's Edinburgh Rifle Volunteer Brigade by Colonel the Right Hon. J. H. A. Macdonald, C.B., M.P., Commandant. It is highly desirable that every regiment should carry its own telegraph appliances, so that it may establish telegraphic communication with its own outposts when acting alone, and that when acting with others telegraphic communication may be more rapidly established by each regiment laying its own cable on reaching camping ground instead of the whole telegraphic plant for a division being carried in separate waggons and worked by a separate department. This field telegraph is designed to enable the necessary plant for telegraphing to be carried regimentally. It consists of—1. One mile of double conductor insulated cable. The main wire is in the centre, and covered with insulating material. The "return" consists of five small wires wound round the covering of the inner wire, and this is again covered. The "return" thus makes the obtaining of an "earth" unnecessary, and also acts as a protection to the main wire. The cable is wound in two lengths on two bobbins. 2. Telephone transmitters and receivers for ordinary speech, or where articulate sounds cannot be heard, a special arrangement by which the Morse alphabet can be read by telephone. (This latter instrument is designed by Samuel Vyle, Esq., late of the telegraph department, G.P.O.) 3. A special coupling for rapidity, and which avoids the use of all screws which might get lost, or sockets which might get clogged in the rough usage of a field telegraph. 4. Poles to carry the cable across roads where traffic might injure it. The guying arrangements of these poles make them adaptable to any position and enable the erecting, taking down, and re-packing to be effected with great speed. 5. Two bicycles to carry the plant. The poles are carried over the handles of the bicycles, and each bicycle has a half-mile bobbin supported on its backbone. The bicycles are trundled by the telegraph troop, the draught being extremely light. If surprised, the poles, which are of comparatively trifling value, can at once be thrown off and the bicycles mounted for escape.

Secrecy of Telegrams.—In the House of Commons on Monday Dr. Cameron asked the Secretary to the Treasury whether the attention of the Postmaster-General had been called to the following statements made by witnesses examined by Sheriff Ivory and published by that gentleman in a pamphlet entitled "A Report by the Sheriff of Inverness, Nairn, and Elgin to the Commissioners of Supply of Inverness-shire":—"Deputy Chief Constable Aitchison.—When he (Captain Mahon) came he sent for the inspector and myself, and we met him then and on several occasions afterwards. On these occasions he showed us various telegrams, for some of which he applied to Sheriff Spens for authority to show us, but he had also shown several to us before he got such authority. . . . A day or two afterwards he came to us with a bundle of telegrams. . . . I think he showed us these telegrams on this second occasion. Captain Mahon showed us (Inspector Macdonald Gillander and me) another telegram on a third occasion. . . . I asked Captain Mahon to allow me to get a copy of these telegrams. He wired for leave to the secretary at Edinburgh, and he showed me the reply telling him not to show the telegrams to any one. I then told him he must show them privately to the Chief Constable at Inverness and to the Sheriff in Edinburgh, and he said he would do so." "Deputy Procurator Fiscal Gillander: Captain Mahon showed me a telegram. He showed me a batch of twenty or thirty telegrams, all or most in different handwriting, one from the postmaster, Portree, and the others from the crofters and their friends;" whether Captain Mahon was "a person having official duties connected with the Post Office," and, if so, whether he was forbidden by the Electric Telegraph Act, 1868, sec. 20, to disclose or in any way make known the contents of telegrams except under certain conditions prescribed in the the Act; whether in any, and if so in how many, of the instances quoted Captain Mahon had obtained the authority prescribed by law for the production of the telegrams; and whether their production was made without legal authority, what steps the Postmaster-General proposed to

Digitized by Google

take for the vindication of the provisions made by law for the secrecy of telegrams and the punishment of Post Office officials who disclosed their contents, or those who induced such officials to make such disclosure.—Mr. H. Fowler: In producing these telegrams, without the necessary legal authority for so doing, Mr. Mahon, who is an assistant surveyor of the Post Office, acted under a mistaken sense of his duty. He believed that in showing the telegrams to the police he was not only not contravening the law, but furthering the ends of justice. Mr. Mahon has been informed that he was in no way authorised to disclose the telegrams in question; but the Postmaster-General is advised that in the circumstances it would not be proper to institute proceedings against him under the Telegraph Acts.—Dr. Cameron said that on the Civil Service Vote for the telegraphs he would call attention to the matter.

HALF A CENTURY.—Fifty years ago is a period well within the remembrance of many of us. Fifty years ago the Queen ascended the throne, and the period is one which permits of comparison. In 1836 Prof. Louyet suggested the use of incandescent lamps for mining purposes. He said:—"It seems to us that here is the place to express our astonishment at seeing that one of the most beautiful discoveries of modern science has not been rendered available for the illumination of the galleries (in mines). We would speak of the incandescence of charcoal produced in vacuum by means of the voltaic pile. . . . There would not be the least fear of danger, since the focus of light would be completely insulated from the external air." The suggestion of 1836 is a reality in 1886, and more than one mine is illuminated by incandescent charcoal in a vacuum, actuated not by the voltaic pile but by the dynamo. In 1836 appears in what may be termed *the* scientific book of the year the following description of plating: "The old method of plating was to apply thin silver leaves over brass articles after they were in other respects completely finished, and is still known by the term French plating; and some English manufactured goods, particularly those on steel, are plated in this manner; such, for example, as plated dessert knives, and other articles for the table. Thus, for instance, the knife being first properly formed in steel, a piece of silver leaf is cut to cover the knife on each side; it is then placed for a short time at the entrance of the plating furnace, during which the union of the silver and steel is completely effected, and it only remains to give to it its proper burnish. With brass goods the polishing is first produced on the original article. They are then rendered free from grease and every other extraneous matter, and the part to be plated is heated to a temperature just below that which causes a change of colour in the metal. Leaf silver is then laid upon the part, and while hot is rubbed with a steel burnisher perfectly dry and clean. By this means the silver was made to adhere to the brass, which, from the action of the burnisher, assumed a fine polish. The goods thus plated differ but little in appearance from those plated according to the present method; but they possess less permanency, and this old practice is almost entirely laid aside by English platers, except in the cases above referred to. According to the present practice, the metal is first produced in sheets plated on one or both sides, and the goods are manufactured at once in the plated form. The first process consists in casting an ingot of alloy of copper and brass, generally about one and one-eighth of an inch in thickness, three inches broad, and eighteen inches long. Great precaution is required in this process to obtain a very perfect ingot, for any holes or other imperfections will produce a general defect in the plate after rolling. The ingot is cast in cast-iron moulds, having rising mouth-pieces to give a certain pressure to the metal, and to allow any impurities to rise above the general surface, and considerable skill is required to have the heat of the mould and that of the metal properly adjusted." In 1886 electro-metallurgy is a larger industry than electric lighting.

ON MAGNETISATION.—A note of M. Mascart to the *Academie des Sciences* says, when a feebly magnetic and isotropic body is placed in a uniform field, it takes a magnetisation parallel to the field, and its coefficient of magnetisation k is the ratio of the magnetic moment for unit volume or intensity of magnetisation to intensity of field. On the contrary, with very magnetic substances such as iron, nickel, and cobalt, one must take into account the reaction produced by the induced magnetism, and the preceding definition is no longer applicable except for cylinders of indefinite length magnetised longitudinally or for closed rings. The calculation of the magnetising force as a function of the external field is very simple in the case of the sphere, the ellipsoid, or an indefinite cylinder magnetised transversely; but, except in the case of very long ellipsoids, the coefficient of magnetisation may vary between very extended limits without the magnetic moment of the body being sensibly modified. The smallest defects of homogeneity have then a considerable influence. The coefficient of magnetisation has often been determined by the use of cylinders placed parallel to the field, and which are likened to indefinite cylinders or to ellipsoids of the same length and middle section; then either the magnetic moment of the body is measured or the quantity of the induced current in a coil which surrounds the mean section when the magnetism is reversed. With rings the method of induced charges only can be employed, and much higher coefficieients of magnetisation are generally found. Hence it may be asked if one of the methods is at fault, and if, for example, there is produced in closed rings a peculiar phenomenon which exaggerates the effects of induction. To solve this question I have employed for the same metal both closed rings and a series of cylinders in which the relation of length to diameter varied between very extended limits. These are the conclusions of M. Mascart's investigations. In general, when a magnetic and isotropic body is of any form whatever, there exists three rectangular directions for which the magnetisation is parallel to the external field with different coefficients, f, f_1, and f_2. These coefficients have the same properties as the coefficients of magnetisation of a sphere of an anisotropic substance which is only feebly magnetic. Let us suppose, for example, that we have f greater than f_1, and that the body is movable round an axis parallel to the direction f_2, in a field of which the component perpendicular to this axis is H. Calling the volume of the body V, and α the angle which the field makes with the direction f, the movement of the couple due to the action of the field is

$$C = V\,(f - f_1)\,H^2 \sin\alpha \cos\alpha.$$

One easily sees that the magnetisation may be considered as the superposition of two others, one constant f_1 H, parallel to to the field H, and producing no couple, the other $(f - f_1)$ H cos α, fixed in regard to the body, and parallel to the direction of greatest magnetisation. This latter is also sensibly constant for small deviations. Such is the case for a magnet which oscillates under the earth's influence. If one wishes to take into account the induced magnetism, one ought then, strictly speaking, to add to the rigid magnetisation a magnetisation of the same sign $(f - f_1)$ H, proportional to the difference of the coefficients relative to the length of the magnet, and to the perpendicular direction. We may add that for steel the mean coefficient of longitudinal magnetisation is much more feeble than for soft iron, which contributes to increase the importance of the transversal magnetisation.

CORRESPONDENCE.

THE POST OFFICE AND THE TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read the reports of Mr. Preece's paper before the Society of Telegraph-Engineers with some surprise. It certainly seems a little strange to me, considering the *wonderful* perfection of the Post Office as laid down by Mr. Preece, that they have not got more subscribers, and also that in those towns where they have opened exchanges—with the exception of Newcastle—they have, I believe, been beaten by the private companies. Mr. Preece holds up the system of Newcastle as an example of perfection in telephony; but if the Post Office are so proud of their arrangements, it seems strange that they will not allow anyone with a knowledge of telephony to see their apparatus, while Mr. Preece has, I believe, visited many of the principal exchanges of the private companies. I should like to know what improvements have been made by the Postal Telegraph-Engineers in telephony; because, though I have had considerable experience of this work, I cannot at present think of any. I agree with the remarks of Mr. Preece that the telephone has been stifled by a "grasping monopoly." Perhaps when Mr. Preece made this remark he was thinking of Newcastle, where a private company opened an exchange, and obtained considerably over a hundred subscribers. The Post Office authorities compelled the company to close their exchange, and then canvassed the town, the company's exchange being closed for about twelve months. This I think is a fair example of a "grasping monopoly." But this is not all. The Post Office finding that they could not stop the private companies, have seriously interfered with their establishing that trunk communication between towns of which Mr. Preece seems to think so highly. This, no doubt, has resulted in delay, but the opposition of the private company to this "grasping monopoly" will probably yet be found inconvenient.—Yours, &c.,

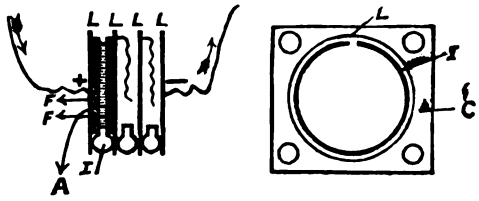
SEABEE.

ACCUMULATOR CONSTRUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am thinking of constructing an accumulator of the following construction, and should be glad of any suggestions or opinions upon it from any of your numerous correspondents as to its practical value.

In the accompanying sketch L L L L are comparatively thin



lead discs; F F are discs of flannel, felt, or "fearnought," and are slightly smaller, one pressing lightly against the side of each plate; A is the acid between the plates; I the india rubber ring (with a flange to separate the bottoms of the "fearnought" pieces), which makes the cell watertight all round with the exception of a small hole at top for filling.

The cell is bolted together by a cast-iron plate C at each end, with long bolts passing outside cells and insulated from the disc at one end. The connections are made to the discs and the current is sent right through the cell, thus oxidising and hydrogenising the two sides of each disc respectively, the result being that the cell acts as a voltaic pile of several elements, and gives a considerable E.M.F. and a small current. Also, there are no troublesome connections to make, or get out of contact, for the current is sent "broadside on" through each plate. The cell can therefore be used for one or two incandescent lamps of high E.M.F., which an ordinary cell cannot do on account of its low E.M.F. The internal resistance and storage capacity can be varied by using plates of greater area; or by coupling two or more of these cells parallel. The object of the "fearnought" is to prevent the oxide from falling down and short circuiting at the bottom of the cell, also to make the cell very portable. Hoping you will be able to insert this in your interesting paper.—Yours, &c.

A CONSTANT SUBSCRIBER.

THE PHONOPLEX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: After having read the article inserted in your number of the 7th inst. on the "Edison Phonoplex," I thought the following might prove of interest.

In using the telephone in the place of a sounder I found that the sounds emitted from the former were improved by substituting for the mica diaphragm a plate of the ordinary metal used for making tins, &c., and raising in the centre of this plate a sort of blister by working the plate backwards and forwards with the forefinger and thumb. This blister (if I may be allowed the term) being in the centre of the plate rests exactly over the magnet of the telephone, so that every current sent through the coil round the magnet causes the magnet to attract this blister, and a sharp "snap" to proceed from the telephone as the result of the attraction. On the circuit being opened the blister springs back, making a decidedly louder "snap." The Morse signals were read according to the duration between each "snap." A primary current was used, but I see no reason why an induced current would not be equally applicable.

I should like further to mention that different tones were produced from the same telephone and plate by arranging various thin pieces of metal under or above the plate at the sides, where the mouthpiece presses on the plate, and also by placing thin pieces of metal across the plate. Not having the necessary mechanical skill, I was unable to adjust the diaphragm permanently, and seldom obtained two similar tones, and had to revert to the blistered plate simply for practicable working. It will be observed that the principle of the above is similar to that of the "pin and ring" arrangement described in your article, and if further developed by skilled workmanship might lead to useful results.—Yours, &c.,

Villa Real, Algarve, Portugal, May 18, 1886. L. C.

ELECTRIC BELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the article in last week's copy of your valuable paper on "Practical Electricity for Amateurs," describing the action of the continuous bells.

As this form of continuous action has many serious inconveniences and defects, I beg to bring to your notice an entirely new form, designed and patented by my firm. In place of the drop relay described in Figure 7 we use an ordinary relay, connected in the usual way, but with this addition—the coil is connected so as to form a shunt circuit between the terminals of the bell. It will readily be seen that on the relay being closed and a current flowing through the bell, part of the current is shunted through the relay, thus keeping the circuit closed. In the case of bells working with a relay, under ordinary circumstances we wind the relay with two wires, the primary or first layers being connected direct to line, and the secondary or second layers in the shunt circuit. The advantages of this simple plan are obvious, as the bell can be made continuous or not at will, and can be stopped and reset from any distance by simply breaking the circuit or short-circuiting the relay. This can be effected by an ordinary press or switch.

Trusting you will excuse this rather lengthy letter.—Yours, &c.,

C. B. CALLOW,

London, E.C., May 25, 1886. (Eck, Callow and Co.)

THE SOLDERING OF WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 14th inst., on p. 6, in an article on "Practical Electricity for Amateurs," you say, respecting the

Digitized by Google

soldering of wires, "*never use spirits.*" I have often seen similar advice elsewhere, but never a reason for giving it. If you would kindly say *why* with such emphasis the use of spirits is forbidden, the information would perhaps be acceptable to others as well as to—Yours, &c.,

May 26, 1886. AN AMATEUR.

A LEGAL QUESTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could you or any of your readers kindly inform me if I can be prosecuted for using, in my own private business, a pair of telephones, same kind as the National Company's instruments, but which I can buy outright in Berlin for a low price?—Yours, &c., ENQUIRER.

Dundee, May 22, 1886.

THE LAW OF THE ELECTRO-MAGNET.

Dr. Frölich, in the *Electrotechnische Zeitschrift*, referring to Prof. Silvanus Thompson's article in the *Phil. Mag.* of January, 1886, says that he by comparison of the formula arrived at experimentally by Dr. Frölich with that arrived at theoretically by Lamont, suggests that the former represents the true law of the electro-magnet.

By the theory of Lamont the increase of the magnetism with increase of current strength is proportional to the difference between the magnetism actually present and the maximum possible value of the same. Let m denote the magnetism present, M the maximum value which this can reach, x the product of current by numbers of coils, k a coefficient which expresses the rise of the magnetism at first. Then, according to Lamont,

$$\frac{d\,m}{d\,x} = k\,(\mathrm{M} - m),$$

whence $$m = \mathrm{M}\,(1 - e^{-kx})$$

According to Dr. Frölich

$$m = \mathrm{M}\,\frac{k\,x}{1 + k\,x},$$

or, developing in powers of x, the two formulæ become respectively

$$m = \mathrm{M}\,k\,x\left(1 - \frac{k\,x}{2} + \frac{k^2\,x^2}{6} \quad . \quad . \quad . \quad . \quad . \quad . \right)$$

$$m = \mathrm{M}\,k\,x\quad (1 - k\,x + k^2\,x^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad)$$

Prof. Thompson thinks that these two developments nearly agree, and that this fact supports his view.

Now Lamont's formula and its development are for all values of the current, whilst the development above given of Frölich's is only true when $k\,x$ is less than 1. For $k\,x > 1$ the development is

$$m = \frac{\mathrm{M}}{1 + \frac{1}{k\,x}} = \mathrm{M}\left(1 - \frac{1}{k\,x} + \frac{1}{k^2 x^2} \quad . \quad . \quad . \quad . \quad . \quad . \right)$$

and this has nothing in common with the development of Lamont's formula.

He goes on to show that, if his formula were theoretically true, the increase of the magnetism with increase of current would be proportional, not to $(\mathrm{M} - m)$, but to this quantity squared.

As an experimental test between the two theories, he refers to the experiments of Prof. Von Waltenhofen with a flat-ring machine with direct winding, and no current in the armature.

In these experiments the value of m, obtained experimentally, agreed far better with that calculated from his than with that calculated from Lamont's formula.

FORMULÆ ON MAGNETIC MOMENT.*

Let us suppose that some one wishes to solve the following problem:—

Given an iron-cylinder (for example, the branch electro-magnet of a dynamo machine) of a certain diameter and length and with a certain number of windings of wire, what is the magnetic moment (when saturation is reached) which will be evoked by a current of so many amperes?

The magnetic moment in such a case is difficult to determine from the laws and experiments given in the treatises of those experimenters who have occupied themselves with the subject.

In the calculation of the answer to the above question, one would have to have regard to

I. The variation of the magnetic moment with the product of the number of windings and the strength of the current.

II. The (according to Dub) direct variation of the magnetic moment with the square root of the diameter.

III. The (also according to Dub) effective variation in cases of this kind with the $\frac{3}{2}$ power of the length of the bar.

The practical usefulness of the empirical formulæ at the command of electro-magnetism has hitherto been so small that you find among practical men little estimation for these dogmas of science, and the reason is that the constant coefficients in the formulæ have not been determined. The formulæ which represent the empirical laws of Lenz, Jacobi, Müller, and Dub contain factors which universally consist of functions of the dimensions of the bar and constants. But the required constant factors have not yet been ascertained.

The three laws given above are represented by the formulæ

$$y = \mathrm{C}\,x$$

$$y = c\,\sqrt{d}\,x$$

$$y = m\,l^{\frac{3}{2}}\,x$$

where y is the moment of the magnet, d the diameter of the bar, and l its length.

The latter two formulæ may be reduced to the single one

$$y = k\,\sqrt{l^3 d}\,.\,x$$

To eliminate the constant k we must make an experiment which will give us the moment y', which a certain bar of length l' and diameter d' acquired when it was magnetised by means of a coil of n' windings, through which passed a current of i' amperes. We shall then have the relation

$$\frac{y}{y'} = \frac{\sqrt{l^3 d}\,.\,n\,.\,i}{\sqrt{l'^3 d'}\,.\,n'\,.\,i'}$$

and can hence determine y.

To render this experiment unnecessary for the practitioner to make, the author by various sets of experiments which have been published has determined k, for which he gives as a rough value 0 135.

Thus we have

$$y = 0{\cdot}135\,\sqrt{l^3 d}\,.\,n\,.\,i.$$

But this formula is only true till saturation is attained. The author's experiments on the magnetisability of iron and steel give the magnetic maximum—that is, the highest attainable magnetisation in a field of infinitely great intensity, as 212·5 units of the C. G. S. system per gramme. Accordingly the magnetic moment of an iron cylinder of length l, and of thickness d (given in centimetres), when magnetised to saturation, is

$$y' = 212{\cdot}5 \times \frac{\pi}{4}\,l d^2 \times 7{\cdot}78$$

if the specific density of iron is taken as 7·78.

The quotient of the actual magnetic moment present by the magnetic moment thus calculated, or $\frac{y}{y'}$, the author has called the "degree of saturation."

* Abstract of a paper by Dr. A. v. Waltenhofen in the *Centralblatt für Electrotechnick.*

LEGAL INTELLIGENCE.

Edison and Swan United Electric Light Company v. Woodhouse and Rawson.

ACTION II.

The trial of a second action, substantially between the same parties, was commenced on Thursday, before Mr. Justice BUTT. This action related to a patent of a communication from America of an invention for improving the carbon burner of an electric lamp by solidifying the carbon employed, and at the same time rendering it uniform as to thickness. By means of subjecting it to an atmosphere of hydro-carbon vapour under heat the thin parts of the carbon become of higher temperature than the other parts and receive a greater deposit out of the vapour, and thus the thickness is made uniform.

Sir Frederick Bramwell, Dr. Hopkinson, and Dr. Tidy were again examined on behalf of the plaintiffs.

The defendants called no witnesses.

The trial was continued on Saturday, and on Monday the SOLICITOR-GENERAL opened the case for the defendants and concluded his speech. He began by saying he did not find it necessary to adduce any oral evidence of his own, having brought out in cross-examination all the facts he thought necessary to his case. The patent in this action is one which was first taken out in America and was patented in this country in American form. American patents, it seems, on account of some diversity of the laws of the two countries, are frequently much longer, and contain more claims than the English patents do. The patent has been amended, as is usual in such cases, and a large number of claims disclaimed, leaving in the result three only—one for a method, described in the specification, of preparing the illuminating part of an electric lamp by heating it by means of an electric current while it is surrounded by a carbon gas or liquid; another for a material for the manufacture of illuminating conductors; and the third for a method of getting rid of occluded gases from the illuminating part of the lamp, combined with a method of previously preparing it. The material is prepared by subjecting it in a hydro-carbon or some other suitable carbon atmosphere or liquid to great heat, by means of an electric current. By this means the thinnest part of the material (having greatest electrical resistance) becomes hottest, carbon is deposited in the pores of the material and on its surface, in greater quantities on the hotter parts, and a dense and uniform carbon is produced; the nature of the carbon is changed to a graphite kind, which is specially suitable for the purpose. Three prior publications were relied on to avoid the patent—in the first place, certain published experiments by Mr. Justice Grove with respect to an improved eudiometer by means of an electric current, in which a carbon deposit was obtained; in the second place some researches of Desprez in 1849, well known in the chemical world, for the purpose of showing that it was possible to fuse and evaporate carbon; and in the third place a communication by Sidot in 1870, in which he described a method of solidifying carbon, and in which he gives electric lighting (not mentioning incandescent lighting) as a purpose for which his material could be applied. Among the arguments that the Solicitor-General adduced to avoid the patent were, that on the construction of the claims they seek to protect the method of preparing the material and the material generally; that in the specification the patentees have asserted, honestly no doubt, that they have invented what they have not invented, and that, as matter of law, that would be enough to avoid the patent; and, further, that the claims are merely for the application of well-known processes and articles to a particular thing, an application which does not result from such exercise of inventive power as to be the proper subject-matter of a patent.

Mr. ASTON replied on behalf of the plaintiffs, and directed the attention of the Court principally to the publications of Messrs. Despretz and Sidot, and reviewed the evidence that had been adduced bearing upon the difference between the knowledge the French writers possessed and the directions given by Cheesborough with regard to incandescent lighting, with the object of showing that in those publications there was no anticipation of the patent in them, the defence set up by the defendants being that there was. He claimed not only that the process adopted by Cheesborough was a new process, but that the material he employed was a new material, and that the patent of Cheesborough was a good one, which had been infringed upon by the defendants.

Mr. Justice BUTT, in delivering judgment on Tuesday morning, said: The plaintiffs in this action are the owners of patent No. 4,847, dated 24th November, 1878, as amended by disclaimer of the 12th Nov., 1884. The claim is against the defendants for an infringement of their patent. The patent is one for making the carbon conductors of electric lamps. The process by which the desired result is obtained is to my mind one of singular beauty and efficacy. The principal features of the process are these. A pencil of ordinary carbon is immersed in a hydro-carbon gas or liquid. A strong electric current is passed through the carbon, and in the course of its treatment the carbon is subjected to a gradual increase of the current of electricity. The defects in ordinary carbons for electric lighting, and the remedies applied by his process are thus stated by the patentee in his specification:—"As is well-known, carbon suitable for electric lighting by the voltaic arc is naturally produced in gas retorts, but generally the rods of carbon used in the regulator lamps so called are moulded from a powdered material. Neither the one nor the other quality of carbon is suitable for electric lighting by incandescence. In both there is a lack of homogeneity. The pencil is not sufficiently hard and dense, because in the first place the heat required to produce the proper character of carbon is as high as 7,000 degrees Farenheit. Such a heat is not obtainable in a retort. In the second place the mechanical sub-divisions of the material and the pressure necessary to produce the perfect article are practically unattainable. A carbon of the ordinary sort when heated by an electric current exhibits points and lines of unequal brilliancy. Carbons prepared by this process, when so heated, glow with a uniform brilliancy throughout." The principal part of that relates to the objections to the use of the ordinary carbon for the electric light. Now comes the improvement. "It has been found that a pencil of carbon immersed in hydro-carbon gas or liquid, and heated to an extremely high temperature by the voltaic current, is not itself attacked, but decomposes the surrounding matter, the carbon of which enters and fills up its pores to an extent impossible except to matter in a very attenuated state, and deposits a perfectly homogeneous layer, generally of a bright gray colour, upon the exterior surfaces. As the carbon increases in size more current is required to maintain its temperature, and if the current is gradually increased in accordance with the demand for it there is apparently no limit to the increase in the mass of homogeneousness of the deposit. The carbon pencils may be cut from this deposit, or the original pencil with its coating may be used in the lamps." In this process it will be seen that the carbon is never in contact with the liquid in which it is immersed, but surrounded by a carbonic gas of very high temperature. Beeswax, balsam, and most oils, if pure, operate satisfactorily—almost any hydro-carbon, in fact, will answer. The peculiar merit of the invention consists in a well nigh perfect adaptation of the means employed to the end aimed at, and this by the automatic action of the materials employed when subjected to intense heat generated by the passage of an electric current. As pointed out, in an ordinary piece of carbon subjected to a high electric current there are observed points and lines of unequal brilliancy. The most brilliant parts are those where the carbon has the smallest sectional area, the resistance of the carbon to the passage of the electric current, and, therefore, the heat being in inverse proportion to the size of the cross section of the carbon. At these points of greatest heat the deposition of the carbonaceous matter by means of this hydro-carbon gas goes on most actively, and so equalises the carbon, which is also made more dense by the operation. That being the patent I do not understand that there is any serious dispute, that, if valid, it has been infringed by the defendants. The answer to the action is not that they have not used the process and the material in question, but that they had a perfect right so to do, because the patent is invalid, inasmuch as the process by which the material was made was known long before the date of the patent in question; that the process and the material were common property, which the public and they, as part of the public, were entitled to apply to any purpose for electric lighting, by incandescence amongst other things. The question arises, therefore, Was the process known before Cheesborough's specification? That appears to me to be the principal question in the case, though there are some other objections made by the Solicitor-General to the validity of this patent. With these objections I propose to deal in the first instance. In the first place a reference was made by the Solicitor-General to lines 5 and 6 of page 12 of the specification. In stating the objects of the invention the patentee there says, after having detailed some others: "To obviate these several difficulties is the object of this invention. To charge the lamp which it is preferred to employ nitrogen gas, and this is produced in the lamp by an improved process in a state of great purity." It is objected that there is no direction in the course of the specification given to the public how to make that improved nitrogen gas, but on looking to the claim, or that part of it which refers to the passage I have read, namely, claim No. 3, I do not see that any claim is made for an improved nitrogen gas. The words of Claim 3 are as follows:—"The herein before described method of preparing the illuminating part of an electric lamp consisting in first obtaining a solid globe containing deposit of carbon by electric action, as set forth, and subsequently, when it is charged with a carbon preservative atmosphere before the flow of such preservative atmosphere has ceased." The nitrogen gas, as I understand it, is there referred to in these words:—"It is charged with a carbon preservative atmosphere." In another part of the specification he suggested that anybody knows how to get or how to make the material used. I point out in the first instance that there is no claim, strictly so called, to the use of the improved nitrogen gas. But on page 14, line 34, of the specification these words are used:—"The lamp being set up, the next important thing is to charge it with an atmosphere which will prevent the consumption of the carbon." And the detailed description of charging the lamp is as follows. Now before that word process he had in the first instance the word "improved"—"improved process" was used originally—"of charging the lamp," which, he said, is as follows. He struck out that word "improved." But it may be said, and I think it was said, "That is all very well, but that refers not to the manufacture or the making of the improved nitrogen gas, but to the charging of the lamp." Well, I cannot agree that that refers only to the charge of the lamp when the gas is made, because when I go on to another part of the specification, on page 14, directly afterwards, I find this "the detailed description of the process"—originally it was "improved process"—of charging the lamp is as follows:—"Various methods of manufacturing the nitrogen gas are well known. Having dried and purified the gas until it stands the test, it is placed in a dry receiver, preferably a bag of vulcanised india rubber." There it is manifest that in starting to describe the charging of the lamp the very first thing he does is to tell you what gases to use. Therefore I think the objection properly considered amounts to little more than a verbal criticism, and there is no substance in it. Secondly, it is said that the patent is void because it describes various methods of making the material, some of which methods will not answer; in other words, that it was misleading the public. The first claim is in these words, "The herein described method of preparing the illuminating part of the electric lamp consisting of electrically heating the same while it is surrounded by the carbon gas or liquid." Now, the "herein described method" mentioned in that claim refers to a passage at page 15

Digitized by Google

of the specification. It is the passage I have read once already, but to which I shall have to refer more than once in the course of my judgment. "It has been found," it says, "that a pencil of carbon immersed in a hydro-carbon gas or liquid, and heated to an extremely high temperature by the voltaic current is not itself in contact, but decomposes the surrounding matter, the carbon of which enters and fills the pores," and so on. And then further on at line 44 he says, "In this process it will be seen that the carbon is never in contact with the liquid in which it is immersed, but surrounded by a carbon gas of very high temperature, beeswax, balsam," and so on. Then he says, "Almost any hydro-carbon, in fact, will answer." We have, therefore, three terms used. He speaks of a hydro-carbon gas, he speaks of a hydro-carbon gas, and of a carbonic gas, and I do not think from the evidence that he meant exactly what he said in using any one of these expressions. Dr. Tidy, I think, said—in answer to the Solicitor-General it was—that the term hydro-carbon gas, as used by him here, is entirely an erroneous one, strictly speaking, in a chemical sense; because, strictly speaking, as I understand the matter, hydro-carbon gas consists of carbon and hydrogen alone, without any other element mingled with it. That is clearly what the patentee was not referring to. I do not know whether very much turns upon that, but when you come to the other two things mentioned—carbonic gas or carbon gas—probably the same thing is indicated. It is said but that will include some gases which, if applied, would not produce the result at all. "It would not," says the Solicitor-General—and he is warranted in the assertion by the answers he got from Dr. Tidy and I think one of the other scientific witnesses—"it would not produce the effect, but would include both carbonic acid and carbonic oxide, and if you use either one of these two ingredients you would fail to get the deposit which you are seeking to get on to your carbon pencil, and so the whole operation would fail." Well, if the specification is really to be read as a direction to the public to use either one of these gases then I should agree that the process as described, which is a futile process, would be misleading to the public. But then I do not really think he meant that, and I think I need not give my own reasons for saying so, because I think I can get them better from the evidence of one or two of the witnesses. Dr. Hopkinson, I think, in his cross-examination says:—"In the sense I understand that the patentee used the word carbonic gas, which would include carbonic oxide and carbonic acid, carbonic oxide and carbonic acid would not effect the purpose of making the deposit." Then, I find Dr. Tidy is examined on the point, and he is asked with reference to the expression "hydro-carbon gas or liquid," "is that a correct expression?" He says:—"From what follows, objection may be taken to it undoubtedly from a strictly chemical standpoint, because, in strictly chemical language we understand by a hydro-carbon a body that contains only carbon and hydrogen, and nothing else. But, I think, by the term hydro-carbon in this specification is clearly meant a body that contains carbon and hydrogen. The word is not used, to my mind, strictly in a chemical sense in the specification, but as a body that contains carbon and hydrogen, though not carbon and hydrogen exclusively," &c. Then, a little further on, he goes on to other points, and Mr. Aston asked him whether reading this specification on the principle of fairly understanding it, any person would be led to try carbonic oxide or carbonic acid, to which he replies, "No, I should not think so. I cannot imagine that anybody would ever dream of trying it. First of all, you could not get a carbon deposit from them by the process that is suggested. Any text book would have told them that." When he comes to be cross-examined by the Solicitor-General he says, "It is not an expression which I should have adopted myself." "Do you not understand by the expression carbon gas, gas of which carbon is one of the constituent elements?" "I do." "Would not carbonic acid be a carbon gas in that sense?" "In that sense, certainly." Now it certainly does appear to me, having regard to the expression used, having regard to Dr. Tidy's statement, which is absolutely uncontradicted, that no man in his senses, no man with ordinary knowledge in his senses would think of applying carbonic oxide or carbonic acid to this operation. It seems to me it would be an extremely hard and unjust construction or interpretation of this specification to hold that the patentee had invited the public to use carbonic oxide or carbonic acid, and so have rendered his patent void. I now come to what I regard as the real question before us. Was this process known before Mr. Cheesborough's specification? A great number of publications have been referred to by the defendants in support of their contention that neither process nor material was new. I think the only publications requiring serious consideration in these relations are those of M. Sidot, which were made in the year 1870, and of M. Despretz at a still earlier period in 1849. I will take Sidot's paper first. No doubt in the course of some experiments he was making, not with a view to electric light, as I understand it, M. Sidot produced a material resembling that which results from the process of the patentee. But it appears to me impossible on the evidence to say that he either described a process that would make the material, or that he did make the material produced by Mr. Cheesborough's process. The evidence satisfies me that the desired result cannot be obtained by the application of external or furnace heat, as contradistinguished from heat produced by electric action as used by Mr. Cheesborough. Sir Frederick Bramwell in his evidence deals with the matter, and I will refer shortly to what he says on the subject. He points out this in substance, that uniformity of heat produced uniformity of deposit per unit of the area, and that is what you do not want in your process for producing a carbon conductor described by Mr. Chessborough. Then there is a passage of at least equal importance in Prof. Dewar's evidence, to which I will now refer. Prof. Dewar is also asked about Sidot's experiments, and he says "Sidot's experiments show that the main deposit of a high heat is on the walls of the tube and not on the wood." "Some would deposit on the wood?" "I have no doubt some would." "Assuming that some would deposit on the wood, are you able to point out any difference in the carbon as the extra deposit put upon it by Sidot and the carbon which is the extra deposit put upon it by Cheesborough?" "I do not think they have anything in common. I have already stated that carbon produced by an electric action at high temperature, which is pointed out by Cheesborough, cannot be produced by furnace operations." It must be remembered that Sidot's operation was purely a furnace operation and nothing else—heat produced by fire from the outside. Prof. Dewar says, "I have said that all carbons necessarily contain hydrogen more or less along with other impurities. That produced by Sidot is carbon, more or less, but not the same material as the Cheesborough carbon. It is not in the same physical condition." That evidence is wholly uncontradicted. [The Solicitor-General pointed out that in cross-examinatiou Prof. Dewar admitted that it was a question of degree.] I fancy I recollect something about that, but I was under the impression that it was in regard to Despretz and not Sidot. However that may be, I think degree has everything to do with the matter, because I think in this electric conductor the degree in which you give it density is of importance, and if Sidot's will not do it I do not think Sidot's paper can be called an anticipation. I now come to Despretz's paper published in 1849. I have no doubt Despretz produced a material in substance very like if not identical with that used for the carbon conductor patented by Mr. Cheesborough, and he got the heat he supplied by means of an electric current. But there is one most important object obtained by the process patented by Mr. Cheesborough, which I think the defendants have failed to show that Despretz's process would yield. The principal object of this patent is to insure the filling up in the course of the treatment of the porous carbon, the porosity of ordinary carbon being a serious objection to its use for incandescent lighting. Now, one part of the process described in the specification is a gradual increase of the electric current. This was certainly no part of Despretz's process. It is an important matter that all or nearly all the witnesses referred to it as a matter of consequence, and Professor Dewar says it is necessary to cure the porosity of the carbon. My note on Professor Dewar's evidence on this point is as follows:—"He" (that is speaking of the patentee) "also points out a gradual increase of the intensity of the current. For Mr. Cheesborough's purpose you must have an intense electric current increased from a less intense one. I find no direction of all this in the anticipation that is in Despretz. Despretz used an enormous current, but he put out the whole at once, and it was not graduated." Then he goes on to Sidot: "I have experimented on Sidot's process, and I say the carbon produced by Sidot is not the same as Cheesborough's—not in the same physical condition. I say you cannot get Cheesborough's carbon from any process carried out by external heating." Then in coming to Despretz he says, "There is nothing in Despretz's papers which would suggest its application to the purpose of getting a good carbon conductor for an incandescent lamp. I have not the slightest doubt but the porosity of the carbon was not cured by Despretz's process, because he did not apply the graduated current." [The Solicitor-General here drew his lordship's attention to apparently contradictory statements on the part of the witness.] I have read all this evidence, and I am trying to understand it as far as I am able. I have read all these passages, and I do not conceal from myself at all that in the evidence of these gentlemen in one part or another there are discrepancies in the text; but the conclusion to which I have come on the whole is that Prof. Dewar, taking the whole of his evidence, taking his examination and cross-examination, intended to abide by this, that you could not cure the porosity without a gradually increasing current. If I am wrong upon that point the defendants will have an opportunity of reviewing the whole of the evidence and setting me right hereafter. Taking the whole evidence I certainly do not feel that I could come to the conclusion that M. Despretz, in the paper in question, has described a process which would enable a competent workman to arrive at the result Mr. Cheesborough has attained. Had I thought otherwise I should have taken time to consider whether the admitted publications in England (for it is admitted in M. Despretz's paper) would have been what is called an anticipation of Mr. Cheesborough's invention. M. Despretz's paper is entitled "Volatilisation of Carbon." It relates to experiments on the volatilisation of carbon—a process the very reverse, as I understand it, which an electrician would desire to bring about for the purpose of electric lighting. The material alleged to be identical with that of Mr. Cheesborough's improved carbon conductor was not a material M. Despretz was seeking to obtain. It came upon him as a surprise, as a disturbing element in the course of his experiments, and interfered with the object he had in view, and its presence does not seem to have been regarded by him with any degree of satisfaction. Moreover, his experiment never seems to have been repeated from the year 1849 down to the time of Mr. Cheesborough's specification. Never during that interval is the material in question applied to any useful or practical purpose. I would here refer to one passage in Dr. Hopkinson's evidence. "Despretz's publication," he says, "has no reference to incandescent lighting, and would not be a publication to which an inventor of an electric incandescent lamp would go for information, and I think when he saw the title of that publication he would rather be deterred than invited to look into it" I am, therefore, of opinion that the invention which Mr. Cheesborough patented has not been anticipated by any prior publication of this process, that the patent sued on is valid, and as its user by the defendants is admitted, there is an infringement for which the plaintiffs are entitled to relief.

Mr. ASHTON made the usual application for an injunction in terms, and an account of the profits, the delivery up of the infringing articles, subject to any arrangement which might be made between the solicitors of the parties, and for costs on the higher scale.

His LORDSHIP acceded.

SPECIAL NOTICE.

With this week's number of "The Electrician" is issued two double-page Illustrations of the Paddington Electric Light Installation.

Subscribers should receive this Supplement GRATIS. Complaints of non-receipt should be addressed to the Manager.

INCANDESCENT LAMPS.

The two legal decisions which have been given within the last few days with regard to the infringement of certain patents by Messrs. Woodhouse and Rawson are of the greatest interest to all connected with the electric light industry. These decisions have put an end to a period of uncertainty, and will no doubt play a very important part in the future progress of the industry. We are not at all sure that the profession as a whole was prepared for the verdict given. The general opinion seemed to be that both parties would gain a portion of their case; but it has ended otherwise, and the holders of the Edison and Cheesbrough patents have been successful at all points. It has now been legally decided that a pencil of carbon, no matter how fine, and a filament of carbon are not one and the same thing. Mr. Edison was the first to use the term "filament" in connection with patents, and Mr. Justice Butt—very justly we think—remarked that the question of the infringement of claim No. 2—that is a claim of the patent No. 4,576, the validity of which was under dispute—depends upon the meaning to be attached to the words in it, "a carbon filament." He went on to say, "If these words mean a carbon filament made as described in the patent, I should hold that there was no proof of its infringement. But I do not so interpret these words. I hold them to mean any carbon filament, however made, which possesses certain qualities or properties mentioned in the specification, or necessarily resulting from the description there given. To answer that description the carbon filament *must*, I think, *possess flexibility and resiliance*. It must be of small cross section offering a high degree of resistance to the passage of an electric current, and it must present but a small surface from which radiation can take place. I am disposed also to think (but on this I refrain from giving a decided opinion) that the degree of resistance must not be less than 100 ohms, as mentioned on page 3 of the specification. Taking the above to be a correct interpretation of the words 'a carbon filament' in Claim 2, it is clear that there has been an infringement of the patent by the defendants."

With regard to the second action the case of the plaintiffs always seemed fairly strong, and the result has created no surprise. At the conclusion of the trial—as will be seen from our report—the injunction asked for was granted. It is very doubtful whether the case will be carried any further, for the appeal would mean another period of uncertainty, and if unsuccessful a very greatly increased expense.

The position of the holders of the Edison, Swan; and Sawyer incandescent lamp patents is this, that they have obtained practically the position of monopolists. The "Sawyer" patent has been generally called throughout these proceedings the "Cheesbrough patent." There are other patents for incandescent lamps. The validity of a number of these would hang upon the decision which has been arrived at, the validity of others may still be disputed, and, in all probability, some will be agreed to be perfectly valid; but although this may be the case, the patents are for lamps which are not so commonly in use as those made under the patents discussed in the recent legal proceedings. There is a danger, then, that the holders of a monopoly may be ill-advised enough to act in such a manner as would, in the end, be greatly detrimental to the progress of electric lighting. We do not think this will be the case, but it is a condition of things which may arise, and which, therefore, cannot be overlooked. A patent gives to its holder a practical monopoly for a term of years; at the end of that term of years the process is open to the world. The holder of a valuable patent is a person or a company which has probably paid a very large sum to the patentee in order to obtain the right of using that patent during the 14 years over which he has the sole control. The purchaser hopes during that period to recoup himself for the initial outlay, and if the process involves manufacture, to obtain a good round sum annually as manufacturing profit, and interest upon the outlay. Unless, however, there is a demand for the article, the purchaser instead of obtaining a profit makes a loss. In the case of these special electrical patents under consideration, very large sums were paid to patentees and the promoters. Companies were formed with a very large capital, and the directors have to consider the interests of their shareholders.

It has been thought that success in these legal proceedings would probably lead to the increased cost of incandescent lamps, and as the renewal of lamps forms a considerable item in all installation work, would probably hinder the growth of such work. The contrary, however, has always seemed to us to be the more probable, and the legal question having once been settled, the holders of the patents will endeavour to pro-

duce as good a lamp as is now produced and at as low a cost as possible in order that at the end of the period when the patent rights expire they may be practically supplying the whole world, and, having so very large a *clientèle*, will be in the position to laugh at all attempts to set up rival manufacturers of their particular speciality. Indeed, we have no reason to suppose but that improvements will still continue to be made in incandescent lamps, just as they have been made during the past two or three years, and that long before the period arrives when the patent rights expire, the manufacturers will have gained such an amount of experience, and have become so proficient in the production of lamps, that no new manufacturers could hope to be able to compete against them. There is no doubt that the life of an incandescent lamp depends very considerably upon the amount of care exercised in the various details of its manufacture, and in this case, as in most others, there are trade secrets altogether outside of anything in the patents.

Let us suppose for a moment that a monopoly should lead to carelessness in the construction of the lamps, and to a higher price being charged. The immediate result would be paralysis of the trade and a languishing demand till the patents expire, unless some new discovery supersedes the necessity of such lamps altogether. It will be easily seen that the definition of Mr. Justice Butt is open to some criticism, and it might be asked how far the Cruto and the Bernstein lamps come under this definition. The filaments of these lamps certainly possess flexibility and resiliance; but the surface of radiation, though small, is larger than that in what we may term the solid filament. The question of resistance does not play an important part in the definition, as that depends upon conditions, and can hardly be deemed a special property of the filament. Under the adverse circumstances suggested, greater attention would be paid to the development of arc lamps of comparatively small candle-power, and it is certain that if a good lamp of this kind could be successfully made there would be a large field for its use. Altogether, then, we think there is no reason to fear that monopoly will in any way endanger the progress of electric lighting. The most disagreeable feature is that monopolists are apt to be autocratic, and young firms, whose requirements may be small, are not always treated with that courtesy and consideration which is accorded to older firms, whose demands are much larger.

THE PADDINGTON INSTALLATION.

Time always works favourably for a good thing, and there is no exception to the rule in the matter of the electric light. Gradually, but surely, the civilised world is being educated, and fifty years hence no one will be able to imagine why in the earlier stages of operation there should have been any doubts or fears about the final result. In the initial stages the work falls into the hands of those who believe in themselves as much as in the matter they have to carry forward. The pioneers in electric lighting are necessarily self-confident men. They feel they can overcome the difficulties before them, and the result we see in continued advance. The successful lighting of Paddington Station and yard makes a distinct step in the onward progress. In our issue of Oct. 28, 1882, we illustrated and described the "largest dynamo in existence," which was constructed by the Telegraph Construction and Maintenance Company to the designs of Mr. J. E. H. Gordon. The dynamo was running at the works of the Company at Greenwich, and was used to generate the current required by the incandescent lamps used to light the works. From the experience gained with this experimental machine the company believed that they saw a solution for the great question of central lighting. We say "the great question," preferably we should say *the* question, for after all is said and done, unless electric lighting upon a large scale from central stations is proved practicable, the future of electric lighting is not worthy the attention of consumers or capitalists. Mr. Edison in New York has shown a certain modicum of success—but it is well known that his experience has been gained at a great expense, and that had he to design and carry out a similar installation he would proceed differently. Upon the Continent of Europe installations of 3,000 to 4,000 incandescent lamps are not unknown; then, in England we have seen what was done on the Holborn Viaduct, and what is done at Victoria and at the Kensington Exhibition. These have all been steps—none, however, so complete or emphatic as that at Paddington. No doubt the initial cost of the Paddington installation has been out of all proportion to the initial cost of a second similar piece of work. We are not, for the moment, troubled about questions of cost, nor should such questions enter into the discussion of success. At Paddington we find a small central building containing machinery for the generation of energy, which energy is distributed and utilised in the form of light on the one side as far as Westbourne Park Station; on the other side to the Great Western Hotel. The light is distributed over the hotel, the station offices, the station platform, the goods yard, the Royal Oak station to Westbourne Park station, platforms and offices, just as gas-light would be distributed from gasworks. The district is one and a half miles long and covers nearly 70 acres of ground. The success at Paddington, if it means anything, means that it is proved beyond cavil that an area enclosed within a circumference whose diameter is 1·5 miles can be supplied from a generating station in the centre of that area. The limit is not shown by these figures; they simply record facts. Within the district described there are over 4,200 points of light; in fact, there are 4,115 incandescent lamps of 25 candle-power each, 98 arc lamps of 3,500 candle-power each, and two arc lamps of 12,000 candle-power each, being by far the largest installation of mixed lights hitherto made.

The distribution of the incandescent lamps is as follows:—Passenger Station offices, 2,009; Great Western Hotel, 472; Goods Station offices, 458; Dynamo Centre (*i.e.*, offices near dynamo-house) and Royal Oak Station, 617; Locomotive and Westbourne Park Stations, 559, or a total of 4,115 lamps. The distribution of the arc lamps is:—Locomotive Station, 5; Dynamo Centre, 10; Goods Station, 34; Passenger Station, 48; and 2 at the hotel corner, making 98 in all. The total light given is said to be equivalent to about 30,000 gaslights.

The difficulties of successfully carrying out such an installation were manifold. This may easily be imagined when it is remembered that it is the first attempt that has been made to lay a great system of underground mains in a busy railway station without in any way interrupting the traffic for a single hour. In parts of the station—particularly in the goods department—tunnels had to be driven for laying the mains, as the contractors could not be allowed to keep the trenches open at all. In other parts, notably in the Westbourne Park main, they seldom got a full minute's work undisturbed by passing trains. It may also be said that the installation at Paddington is the first effort that has been made in England to give a continuous supply of the electric light on a very large scale analogous to that of the rival illuminant gas. In most other installations electricity has been merely an accessory to gas. Here, however, it is intended that the electric light should entirely supersede gas, and the Great Western Company's gas works, from which they supplied their own light previous to the installation, will, it is expected, be closed in a very short time. In places like the "Colonies," for example, although there is a great illuminating power required, the conditions under which it is supplied in no way approximate to the necessities of a house to house supply, as is the case in the installation we are now describing, for the simple reason that there are practically in the former no switches to bring the light under proper control. At Paddington, on the contrary, the lamps all over the extensive district embraced by the installation are entirely under the immediate power of the users, and are turned on and off at will just as gas, and this, too, without the necessity of communicating with the engine house. This is mani-

Digitized by Google

festly an advantage which will in the future add to the popularity of the electric light. Suppose, for example, that on some bright day in a given district only 50 or 60 lamps were burning at a given time, and the sky became suddenly overcast to an extent necessitating the use of artificial light—an experience with which dwellers in the metropolis are unhappily too frequently familiar in the winter and spring months—as many lamps as might be required could be turned on in a few minutes by the system adopted at Paddington without in the least injuriously affecting the rest of the installation.

The dynamo room is somewhat nearer the Paddington end of the district than the Westbourne Park end. At one end of the dynamo room is a raised platform, carrying a large and prominent switch board, and a number of Gordon's multiple main regulators, one of which is shown in Fig. 1. The current is generated by the Gordon machine, similar, but larger than the experimental dynamo described and illustrated in *The Electrician*, Vol. IX., pp. 595-6-7-8-9. Figs. 2 and 3, taken from photographs of the dynamo room before the machines were encased in their wooden houses, will, however, give a very good idea of the external appearance of these brobdignagian machines. Three of these dynamos are used, each weighing 45 tons. The sole plates are 18ft. long, and the revolving magnet-wheels are 9ft. 8in. in diameter, and weigh 22 tons each. They run at a uniform speed of 146 revolutions per minute. The dynamos are of the alternating current type, wound to give an E.M.F. of 150 volts. The field-magnets are excited by three Crompton direct-current machines, each of the latter driven by a Willans engine, while each of the former is driven direct by compound tandem engines by Rennie.

The exciting machines are of the Crompton type, and they are what are usually called slow speed machines. They are driven direct by high speed Willans engines, running at about 450 to 500 revolutions per minute. The output of the machines is about 25,000 watts, the E.M.F varied as desired between 110 and 130 volts. The armatures consist of copper bars, and the general appearance of the sets is similar to those used for lighting Old London at the Inventions Exhibition last year. (Fig. 4.)

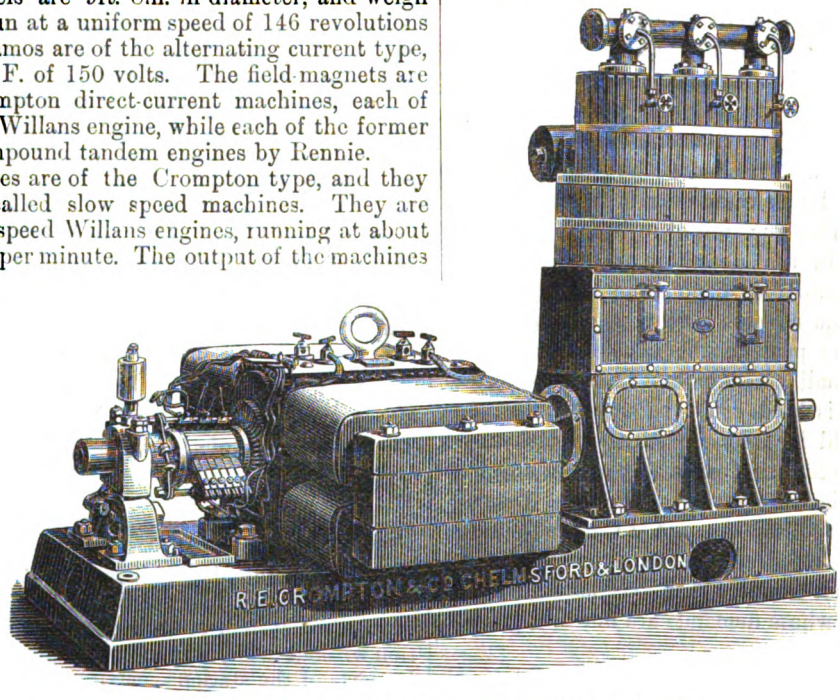

Fig. 4.—Crompton Dynamo, driven by Willans Engine.

The Rennie engines are of the vertical inverted cylinder type, each engine having two low-pressure cylinders and two high-pressure cylinders on the top of them, and each engine is capable of indicating 600 horse-power. The two high-pressure cylinders are each 14in. diameter, the low-pressure 23in. diameter, and the engines have a stroke of 1ft. 6in. The crank shaft is 8in. diameter in the bearings.

Each dynamo is provided with 28 field magnets carried on a revolving wheel. The core of each magnet is cylindrical, 3ft. long and 6in. in diameter. It passes through a disc and protrudes at each side, and has two coils of wire slipped on at the sides. The coils, which weigh 160lbs. each, are kept in their places by the pole plates secured to the ends of the magnets. The central disc is built up of segments of boiler plate riveted together with butt strips, having in the middle an armour plate ring, rolled at the works of Messrs. Cammell and Co. They are steadied, on the principle of a bicycle wheel, by two boiler plate cones, which are kept apart from them by massive iron castings flat at one end and conical at the other. The dynamo shafts are 8in. in diameter, and are run in white metal bearings, the exciting current being taken in by two brushes, which press on insulated brass contact rings. The fixed coils are wedge-shaped, and are each capable of generating about 5 horse-power of electricity. The wires from the fixed coils pass from the dynamo pits under the floor through safety fuses, being separately connected to massive brass bars on the wall. From these bars heavy cables are led to the distributing apparatus in the gallery. In this connection it may be observed that the speed of the exciting machine is regulated by a worm wheel on the stop valve, worked by a rod communicating with the large engine, the dynamo of which is connected with that particular exciter. It may also be mentioned that the exciters are interchangeable—that is to say, that any one of them can be connected to any dynamo when a corresponding change is made on the handgear for driving. Pairs of voltmeters are conveniently placed above each machine, where the engineer may see them, thus enabling him at any moment to control the speed of the exciter in accordance with the indications registered on the voltmeters. A meter is placed in circuit with each exciter, and a glance at it at once shows what the engines are doing without the trouble of taking a diagram. The current of the large machines is measured by an electro-dynamometer inserted in the circuit of one coil of the armature, its readings being afterwards multiplied by the number of coils in the machine. On bright days, when not more than 150 lamps are required, two of the exciters are connected in series and are joined direct to the mains, and the big machines are not run. In that case the current passes through an ordinary ammeter provided with a short circuit.

A very ingenious arrangement has been devised in order to perform the double function of reducing the noise produced by the dynamos and at the same time of ventilating the building in which they are worked. This has been satisfactorily accomplished by incasing the dynamos in a structure of double wood and felt casings (Fig. 5), with double glass windows, made in such a way that the dynamos act as their own fans, withdrawing the air, and with it the noise, from the room, and afterwards expelling the air through wire gauze screens, and discharging it on the railway line away from the houses. Thus a circulating current of fresh air is continually kept up in the chamber, maintaining in it a cool, equable temperature, an appreciable advantage to both the workmen and machinery. There are three engines employed for driving the dynamos, as we have said, and the particular type has been

Digitized by Google

adopted with the object of getting over the difficulty of the unequal straining of the cranks which usually results from great differences of load when the engines are running at constant speed, and when the cylinders are placed side by side in the ordinary manner. After many experiments it was found most convenient and serviceable to use the old-fashioned Porter governor for the main engine, and hitherto its working has been found all that could be desired.

Upon the platform in the dynamo room, access to which is obtained by the stairs as shown in the illustration, the most prominent object is the large switch-board. This switch-board is of slate, and is 18ft. long and 8ft. high. Here any dynamo can be connected to either or both circuits, or an exciter or exciters can be connected direct to the circuits. One dynamo can be exchanged for another without interrupting the light, or any particular district can be disconnected for testing.

As we have said, by means of the switch-board one machine can be exchanged for another instantly, without causing a perceptible flicker in the light. This is effected when required by starting the spare machine at speed on open circuit, and working its exciter up till the current is the same as that of the machine which it is intended to replace. When this is done two men, working simultaneously, turn the switches over on the big board, and transfer the load from one machine to the other. The switches consist of massive bundles of copper strip about an inch square, and are curved in an eccentric manner, so as to jam home and make a good contact. Behind the switch-board is the divided main apparatus. The feeding centres are like large cupboards, and each is placed in a central

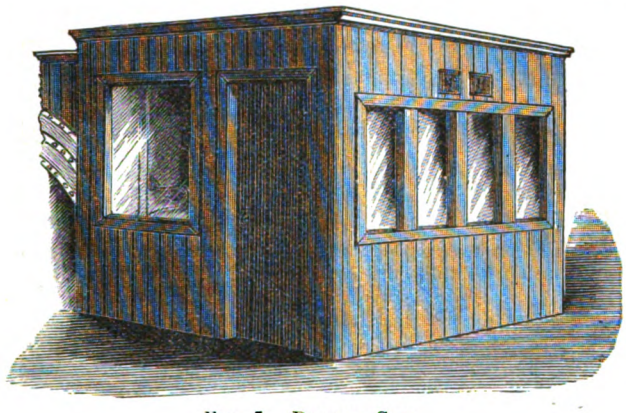

Fig. 5.—Dynamo Case.

part of its district, and is provided with a switch-board, from which the current is distributed to the different portions of the neighbourhood in which it is situated. These centres are all in telephonic communication with the gallery of the dynamo room. This is essential for testing purposes, because where there are a number of wires they have to be disconnected one by one simultaneously at two ends.

Fig. 1 shows the divided main apparatus, which is considered the most important part of the system, for by its use the quantity of copper required in the feeding mains is reduced to one-tenth of that used in the ordinary method. The principle of it is as follows :—In any feeding main the electric pressure at the far end is less than that of the dynamos. The fall of pressure is greatest when all the lamps that the main has to carry are on. If the main is thick and expensive this maximum fall is small, if thin and cheap it is great. When only a few lamps are on the fall is very small. Thus, as lamps are turned on and off there is in an ordinary main a variation practically equal to the fall. As only a variation of not more than 2 per cent. can be allowed, very thick mains have to be used on the ordinary system, so that the fall may not be more than 2 per cent.

The object of the divided main system is to allow a fall of 20 per cent. to be used. For this purpose the feeding main consists of a bundle of wires, as shown at A A (Fig. 1), connected into one at each distant feeding centre. There are five of these distant centres in the district, and they are supplied by twelve feeding mains. Contact apparatus worked by wheels in the gallery allows the component wires of each feeding main to be disconnected one by one. As the wheels are turned round more or less of the component wires are used to form the main cable. Fine wires come back from each feeding centre to the gallery and actuate voltmeters and pilot lamps so that the exact brightness of the light in every part of the district can be seen in the gallery. Suppose, now, a certain number of lamps are switched off in, say, the hotel, its pilot in the gallery brightens a little and calls the attention of the attendant to the voltmeter. He then moves the contact wheel, and, cutting out a segment of the main, reduces its total section, and so increases its resistance and brings back the pressure to its normal value.

To sum up, the thickness of an ordinary main is constant, and, unless it is very large, the variations of current caused by turning lamps on and off cause variations of electric pressure. In the divided main the section is variable, and is kept always proportional to the current the main has to carry, and so the electric pressure is kept constant with a main of one-tenth of the section required for the ordinary system.

A double system of mains is laid throughout (not twice the necessary quantity of wire, but instead of one main of a certain section two of half that section), and in every room, building, yard, &c., half the lights are on one circuit and half on another, and these two circuits are worked by different machines, so that in case of either system breaking down no single room would be left in darkness. In some of the bed rooms of the hotel, where only one lamp is paid for, two are erected on different circuits, and a switch is provided so that either can be lighted at the desire of the inmate, but not both at once.

The pressures in use at Paddington are: "Dynamo centre," *i.e.*, district near the engine house, 150 volts (for this part the divided main is not used); passenger and goods stations and hotel, 120 volts; locomotive station and Westbourne Park, 100 volts. Different lamps are, of course, used in the different districts.

An important provision has been made for the localisation of faults in the system. When an accident happens to a submarine cable it is sufficient, as a rule, to localise the interruption approximately, that is to say, that the cable may be grappled from the repairing ship at a point a hundred yards or so from the indicated position of the fault without causing any serious inconvenience. But in underground mains it is necessary to ascertain the position of any defect within a few yards, because it is obvious that an error in this respect would mean so much expensive excavation. Special arrangements had therefore to be made to meet such a contingency, and they have been entirely successful. In the matter of trimming the arc lamps a great number of special contrivances had also to be devised, as may readily be inferred from the fact that some of these lamps are supported on posts about 45ft. in height, whilst others are suspended from the roofs of the different buildings, which are constructed with girders of varying shapes and dimensions, each requiring a method peculiar to itself of lowering the lamps for the purpose of being trimmed. As a proof of the great trouble which this apparently simple matter has caused the engineers, it may be remarked that between twenty and thirty different patterns of pulleys had to be designed for the purpose.

Fig. 6, the (home district) dynamo-feeding centre switch-board. The different plugs communicate with the various corridors, platforms, &c., by means of wires. Each has its own fuse, which can be disconnected, so as instantly to localise any fault. There is also a means of measuring the current taken at any moment at any corridor, &c., or any pair of arc lamps. This is done by inserting two large plugs connected to the electro-dynanometer in holes, one on each side of the contact plug. The latter is then removed, and it passes through the dynanometer. The plug boards consist of a central brass block, to which the mains from the big switch-board of the home centre or the end of the divided main in the case of the distance centres are connected. Pairs of small blocks joined to each other by a safety fuse are fixed so that they can be connected to the central block of plugs. Wires from these smaller plugs lead to the different corridors, &c.

Captain Cardew's voltmeters are used throughout, but with considerable modifications in point of structure. Pilot lamps are placed beside each meter in case of its breaking down. Immediately under the staircase leading to the gallery where the switches and distributing plant are situated, the mains from the dynamo terminals are conducted up through a covered way, being thus entirely concealed from view. All the voltmeters are reset by a standard every morning. From the gallery a telegraph wire communicates with the main engine, by means of which the light can be raised or lowered if required.

It is intended shortly to light all the signals about the station. In order that this may be safely done two lamps are placed in each signal lantern, one on one dynamo and one on the other. By means of a switch in the signalman's cabin both lamps can be extinguished, or either can be lighted at will, but not both. If from any cause a lamp filament or wire broke, or from any other accident the lamp went out, an alarm bell at once rings in the signalman's cabin, and a disc shows which of them is wrong. The bell goes on ringing until the signalman puts over the switch, and lights the spare lamp. At the same time another bell rings at the dynamo room, and the disc comes up to show at which cabin the lamp is defective. This bell goes on ringing until the lampman arrives at the signal cabin, so that the officer in charge can tell how long this individual has been on the road. If a lamp breaks, the light is out only for a second, and the lantern depends on one lamp instead of two for a few minutes. The apparatus used consists of two little solenoids (Fig. 7), one in circuit with each of the lamps. If either is pulled down while the lamp is burning, the bell circuit is broken. But if both lamps are out at once, both cores fly up, and the bell circuit is completed; then the alarm bell rings, and the disc comes up in the way usual with electric bell arrangements. When, however, the bell is switched out purposely by the signalman the bell does not ring, as the switch, which extinguishes the light, is so arranged that before doing so it breaks the bell circuit. A full-sized model of this device is at work in the engine room, and all the cabins and signals are wired and fitted with the apparatus. It is thought advisable, however, not to connect it until the plant has been at work for a few weeks longer.

Fig. 8 shows a domestic meter. The Gordon meter is not used at Paddington, as the light there is supplied at so much per annum, and not by meter. But a single meter is put up for experiment and measures the light supplied in the dynamo room and the different offices. It consists of solenoids which pull cores into them against a counter weight, according to the number of lamps at work. This, as they are drawn in, causes a snail wheel to revolve, and increases the distance from the upper edge of that wheel to a point vertically over it. A train of clockwork causes an arm to fall every quarter of an hour from a fixed point to the then position of the upper edge of the snail wheel. If no lights are on it falls no distance. If many lights are on it falls a distance proportionate to the number. As the arm rises again it engages a train of counting wheels. Thus the meter consists of a free galvanometer and apparatus which searches every quarter of an hour for the position of the galvanometer needle and adds together the lengths of all the journeys which it makes in those searches in, say, three months. The clockwork is not wound up, but is driven by a tuning fork, actuated by a fine wire magnet into which the alternating current is admitted. It runs at a uniform speed whether few or many lamps are on; but when no lamps are on, the balance weight of the cores lifts a contact spring and stops the clockwork, so as to save wear and tear.

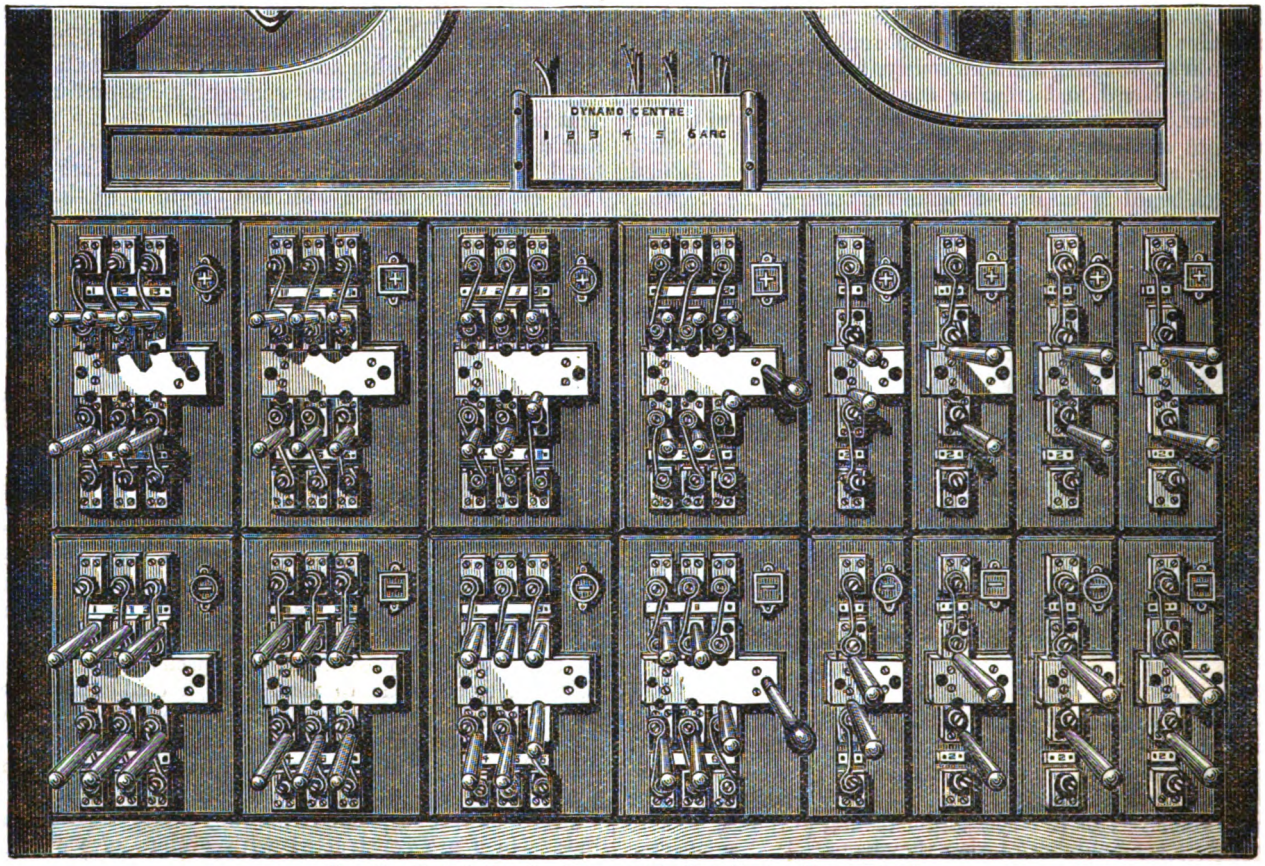

Fig. 6.—Switch Board. Dynamo-Feeding Centre, Home District.

Steam is supplied to the engines by two rows of pipes connected with nine large boilers (Fig. 9), not more than five or six of which are in use at one time, so that in case of a pipe bursting, one line of pipe can be shut off without interrupting the supply. Some idea of the elaborate nature of the arrangments may be gathered from the fact that there are forty-two stop valves in use, independently of small cocks. The feed water is heated by a portion of the waste steam, which is turned into a receiver where it meets a spray of water from the tank, heating it as it falls. To equalise the pressure, the pipe is connected to a hydraulic accumulator weighted at 180lb. to the square inch. As the boiler pressure is 120lb. this gives a difference of 60lb. to force the water into the boilers. The speed of the feed pump is regulated

Digitized by Google

by a throttle valve connected by a link to the hydraulic accumulator, and when the latter is at the top of its travel it stops the pump.

The water is supplied from three independent sources, *i.e.*, the Grand Junction Company's mains, the Canal Company's supply, and the hydraulic accumulators used to work the cranes and turntables in the station. Water can be introduced into the boilers by three methods, *i.e.*, (1) cold, by the hydraulic pressure used for working the cranes, &c., in the station; (2) cold, by injectors; (3) hot, by the steam pump and ram just described. The first two methods are only used in case the hot-water pump breaks down. Welsh coal of a special quality is used, and the furnaces are specially constructed, so that no smoke whatever is produced. The invisible products of combustion and the waste steam are discharged through two chimneys, 90ft. high, whose tops are far above the chimney pots of the neighbouring houses.

FIG. 10.—Chandelier in Board Room.

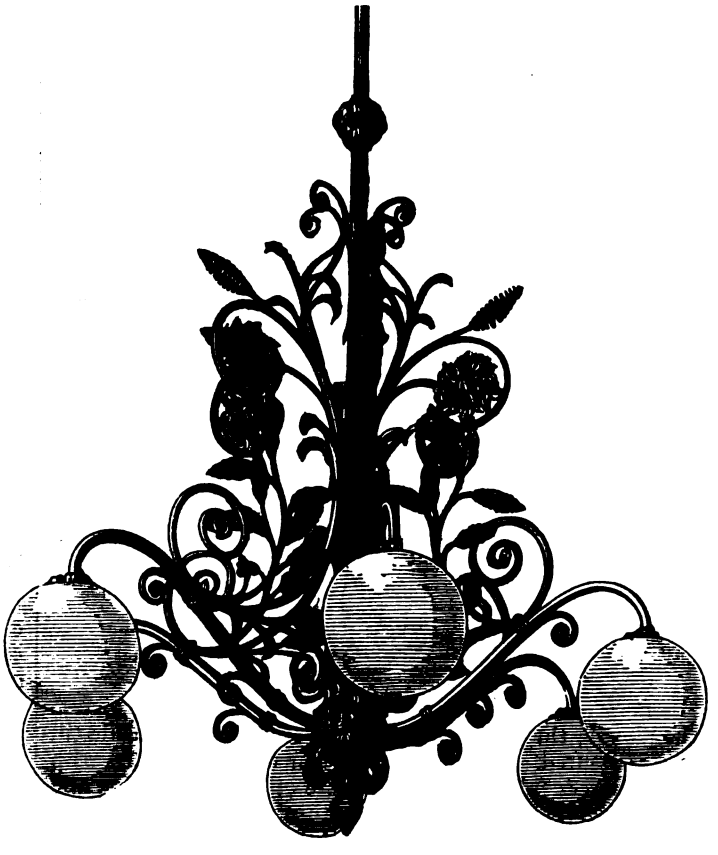

FIG. 11.—Chandelier in Sir D. Gooch's Room.

The contract with the Great Western Railway Company provides that every lamp should have a separate switch, so that it can be turned on and off independently. The incandescent lamps are entirely under the control of the users, and out of the control of the contractors, exactly as in the case of gas. Th current is always on day and night, except for three hours in the daytime on Sunday, when it is interrupted for testing purposes. The contract supply was commenced on April 21st, and has continued without hitch or difficulty up to the present time.

Figs. 10 and 11 illustrate some of the chandeliers, designed and manufactured by Messrs. Cooper, of Great Pulteney-street, these being placed in the Board room and Sir D. Gooch's room at the Paddington Station. The arc lamps are Crompton-Crabb DD type, specially adapted for alternating currents. Through the large lamps facing Praed-street a current of 40 amperes is passed, thus making them the largest lamps in constant use.

The Crompton-Crabb lamps are notable for their simplicity in construction, and consequent non-liability to get out of order. They can be made for use with continuous or alternating currents, and for running parallel with incandescent lights. It is found that the use of alternate currents with these arc lamps has a tendency to keep the light extremely steady. A lamp mast is shown in Fig. 12. The incandescent lamps are Swan lamps.

In the case of an accident occurring on the railway, such as an engine running off the line, a pair of arc lamps supported on tressels are always in readiness outside the engine house, together with a handbarrow, on which is a drum containing 400 yards of wire. These lamps can be instantly carried to any point of the district. The wire may then be unwound and connected to the nearest arc lamp post or feeding centre, when the light can be at once put on.

The arcs are two in series, each pair being in parallel with the incandescent lamps, and are fed from the same mains. In series with each pair of arc lamps is a resistance coil of peculiar shape, calculated from a formula of Prof. Clerk-Maxwell's to have the maximum possible self-induction. These resistances are so adjusted that when the lamps are right they have very little effect, but directly the carbons run together the resistance increases greatly and chokes any rush of current. Tin safety fuses are used throughout to guard against any possible fire-risk. The current passes through nine of them in its way from the dynamo to any lamp.

Some idea of the magnitude of the work may be formed from the following miscellaneous figures:—500 miles of wire

Digitized by Google

have been used. The wires in the offices and corridors are enclosed in wood casing. Of this 12 miles have been used. The casing is fixed to the walls by 94,000 screws. The underground mains are contained in thin iron troughs, like rain-water gutters with lids; of these 140 tons have been buried. About 25,000 joints have been made; 20,000 labels have been used for ends of wire; 2 tons of terminals and connectors have been used; 260 yards of massive masonry (in a number of short lengths) have been built under the lines to prevent the weight of the trains crushing the mains where they cross under the lines.

The incandescent lamps are all in parallel.

We have said enough in the description of this installation to show the great care that has been taken to obtain success in every detail. Mr. Gordon must be congratulated upon the success attained. First known to the world as an earnest student and a successful writer, he has now shown that he can carry out his ideas in practice. With regard to the Telegraph Construction and Maintenance Company, success is only what we expect in whatever they undertake. Having put their hands

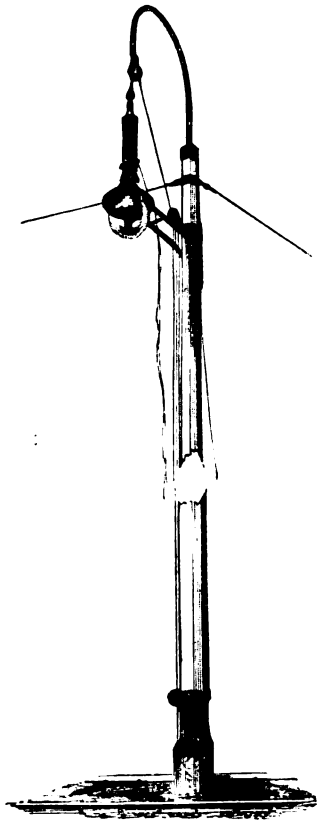

Fig. 12.—Arc Lamp Mast.

to the plough, they neither look backward nor turn aside till success is assured. We never hear their name associated with failure. Successful in the manufacture of cables, in laying and in picking up cables, they have now turned their attention to an industry which bids fair to rival their cable work in extent, and we can but express the hope that their success in the later venture may be far greater than in anything they have hitherto undertaken. The credit of the Paddington work must be given to Mr. Gordon, who has, we believe, had the complete management of the work, and has been ably assisted by Mr. F. Bailey, M.S.T.E., the resident engineer. In conclusion, there is one remark we should like to make as to the success in getting rid of noise at the central station. It is almost impossible to distinguish any noise, even in the next room to the dynamos when they are running full speed. The effect of enclosing the machines is wonderful, and one of the most satisfactory items of detail.

Telegraph Stores Wanted.—The Directors of the North-Eastern Railway Company invite tenders for Telegraph Apparatus and Telegraph Wire and Line Stores. Further particulars will be found in our advertisement columns.

TELEGRAPHING WITH TRAINS.

The Phelpsian system of telegraphy with trains in motion is based on the electro-dynamical induction between a cable placed between the rails and a wire frame of large dimensions in the carriage.

Another method lately brought forward by Edison and Gilliland depends on statical induction. Fig. 1 represents the arrangement in the station, Fig. 2 that in the carriage. The metal roof of the carriage is united with the reversing key S. If the key is to the left it closes the circuit through the telephone T, which is connected to earth by connection with the wheels. Thus all is ready for receiving a message. If S is to the right, it closes the circuit through the secondary coil of an induction apparatus G. The primary coil is in circuit with an automatic contact-breaker or interrupter which may be regarded as a modification of the well-known Wagner's hammer. A spring, R, which vibrates pretty quickly, is kept going by a battery, B (the upper one in the figure), and alternately opens and closes the primary circuit, in which is the other battery. In the primary circuit there is an ordinary Morse key, K, so that the current can only pass in it when this is closed.

Suppose S to the right and K closed, then the primary coil is traversed by an intermittent current, which would engender

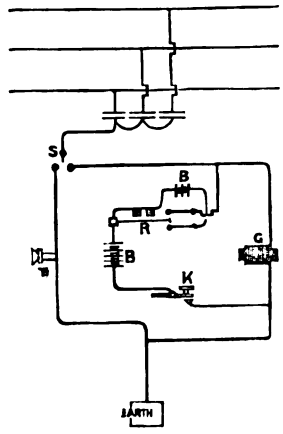

Fig. 1.

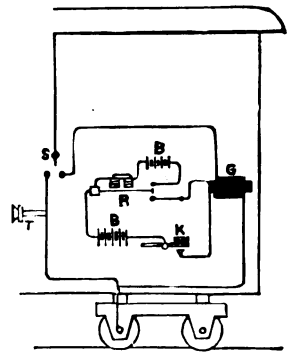

Fig. 2.

induced currents round the secondary coil if its circuit were closed. Instead of this being the case one pole of the coil is connected with the metal roof of the carriage, which thus receives an alternately positive and negative charge. The charges of the roof induce charges of opposite sign in the railway telegraph wires in the neighbourhood. The wires are in connection, as Fig. 1 shows, with one set of coatings of the condensers, whilst the other coatings are connected with an apparatus at the station like the one in the carriage. If one apparatus signals, a musical note is heard in the telephone of the other, which is interrupted by the Morse key, just as in Morse telegraphy. Thus a telegraphic understanding is rendered possible. In place of the condensers Edison has also employed induction coils.

The ordinary telegraphic currents which were passing in the line during the experiments were not prejudicial to the communication, which fact may be ascribed to the circumstance that these produce less strong charges, and besides subside less suddenly.—*Centralblatt für Electrotecknik.*

THE COLONIAL AND INDIAN EXHIBITION.

The arrangements of the Conference Committee, of which the Duke of Manchester is chairman, are now fairly complete. The meetings are open to all visitors to the Exhibition. The following papers will be read:—"Imperial Federation," by Mr. F. B. Labilliere; "Our Colonial Wool Supplies," by Mr. P. L. Simmonds; "Importation of Grain and Bread-Stuffs from the Colonies and India," by Mr. S. B. L. Druce; "South Africa as a Field for the Emigration of the Industrial Classes," by Mr. Arnold White; "The System of Land Transfer adopted by the Colonies," by Mr. J. D. Wood; "The Mineral Resources of India, by Prof. Valentine Ball, F.R.S.; "British-Grown Teas," by Mr. L. J. Shand; "Indian Carpets," by Mr. Vincent Robinson; "Emigration to the Colonies," by Mr. F. Young. The papers will be followed by discussion.

RELATION OF "TRANSFER-RESISTANCE" TO THE MOLECULAR WEIGHT AND CHEMICAL COMPOSITION OF ELECTROLYTES.*

BY G. GORE, LL.D., F.R.S.

In the full paper the author first describes the method he employed for measuring the "resistance," and then gives the numerical results of the measurements in a series of tables.

He took a number of groups of chemically related acids and salts of considerable degrees of purity, all of them in the proportions of their chemical equivalent weights, and dissolved in equal and sufficient quantities of distilled water to form quite dilute solutions. The number of solutions was about seventy, and included those of hydriodic, hydrobromic, hydrochloric, hydrofluoric, nitric, and sulphuric acids; the iodides, bromides, chlorides, fluorides, hydrates, carbonates, nitrates, and sulphates of ammonium, cæsium, rubidium, potassium, sodium, and lithium; the chlorides, hydrates, and nitrates of basium, strontium, and calcium; and a series of stronger solutions, of equivalent strength to each other, of the chlorides of hydrogen, ammonium, rubidium, potassium, sodium, lithium, basium, strontium, and calcium. A series of similar liquids to those of one of the groups of acids, of equal (not of equivalent) strength to each other, was also included.

As electrodes he employed pairs of plates of zinc, cadmium, lead, tin, iron, nickel, copper, silver, gold, palladium, and platinum; and separate ones formed of small bars of iridium.

He took each group of solutions, and measured in each liquid separately, at atmospheric temperature, the "total resistance" at the two electrodes, and the separate "resistances" at the anode and cathode respectively with each metal, and thus obtained about seventy different tables, each containing about thirty-six measurements, including the amounts of "total," "anode," and "cathode resistance" of each metal, and the "averages" of these for all the metals.

By comparing the numbers thus obtained, and by general logical analysis of the whole of the results, he has arrived at various conclusions, of which the following are the most important:—The phenomenon of "transfer-resistance" appears to be *a new physical relation of the atomic-weights*, attended by inseparable electrolytic and other concomitants (one of which is liberation of heat, *Phil. Mag.*, 1886, Vol. XXI., p. 130). In the chemical groups of substances examined, *it varied inversely as the atomic-weights of the constituents, both electro-positive and electro-negative, of the electrolyte, independently of all other circumstances*; and in consequence of being largely diminished by corrosion of the electrodes it appeared to be intimately related to "surface-tension." He suggests that such corrosion may be a consequence, and not the cause, of small "transfer-resistance." The strongest evidence of the existence of the above general law was obtained with liquids and electrodes with which there was the least corrosion and the least formation of undissolved films; those liquids were dilute alkali-chlorides, with electrodes of platinum.

This research is an extension of a former one on "Transfer-resistance in Electrolytic and Voltaic Cells," communicated to the Royal Society, March 2, 1885. Further evidence on the same subject has been published by the author in the *Philosophical Magazine*, 1886, Vol. XXI., pp. 130, 145, 249.

* Abstract of Paper read before the Royal Society, May 20, 1886.

COMPANIES' MEETINGS & REPORTS.

The West India and Panama Telegraph Company (Limited).

The eighteenth ordinary general meeting of the members of the West India and Panama Telegraph Company (Limited) was held at the City Terminus Hotel, Cannon-street, on the 27th inst., under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, we meet under the somewhat depressing influence of declining traffics. Whether a railway, a steamship, or a telegraph company, a decline in traffics, I think, has been painfully brought before the notice of everyone interested in undertakings of a similar sort. In the present year, it may be noted, if the traffic receipts that we had two years ago—in 1883—had continued what they were then, we should have been in a position, putting the same amount as we do now to the reserve fund, to pay a dividend of 5s. a share extra this year on the preference shares. The whole difference is occasioned by the depression of trade, which is general, and particularly felt in the West Indies. Upon the details of the accounts I have very little to remark. I think they are perfectly featureless as far as expenditure goes, and they are very much on the same lines as they invariably are with us. The balance that we have to deal with, of £14,817, is practically the same as it was at this time last year, although the revenue has fallen off; and the reason of its being the same is to be accounted for by the chance during the six months of our having had to bring the ships home to fetch out new cable, while the expense of the voyage is charged to cable account. They are earning freight which otherwise we should have had to pay for to the carriers of that cable, and the saving effected in that way enables us to show a balance of about the same amount as we did this time twelve months. In the present condition of affairs there is nothing for us to do but to maintain the cables, so as to enable us to take advantage of any improvement in trade that may come about; and in connection with that consideration it is satisfactory to be able to report as we do in the third paragraph that the original Cuba-Jamaica cable which has been interrupted and inoperative for seven years now, has been repaired with a very much smaller expenditure of cable than I anticipated the last time I met you. The interruption of this cable was in the northern half of the section, and in very deep water, and as I told the last meeting, although we could get hold of the cable, so great was the depth that it was impossible to bring it up to the surface of the water. It was not in a condition to bear its own strain in lifting it to a very great height. The ship "Grappler" came home in order to take out the cargo of cable, 250 knots, and we then had an opportunity of discussing the question with the captain who had been engaged in these repairs. We left him a good deal of latitude as to what his operations would be, but we sketched out, of course, what we thought would yield us the greatest success, and the course that would yield us the greatest success means the saving of the greatest amount of the old cable. He went to where he found 1,300 fathoms of water, which is a good depth, and picked up the cable there, slipped in new cable of 46 knots, and ran to Santiago. There then remained about 25 knots to put in at the Jamaica end, and that was a total expenditure of 71 knots, whereas I thought at one time that we should have to relay the whole of the cable. The cable is put through, and is working very satisfactorily now. The other cable that has given us so much difficulty—a cable very much in similar circumstances to the one I have just spoken about—the original Jamaica-Porto Rico cable failed in November last. At the last meeting we were all rejoicing at the very successful repair that we had made on that cable. It had been for a long time interrupted, and it gave us great difficulty; but in 2,400 fathoms of water the cable failed last November—not in the new cable that we had put in, but in the original cable that had been lying there for fifteen years. It is impossible to get hold of the cable at that depth, and if we could get hold of it we could not get it up to the surface of the water, and we must go to a considerable distance on either side of it until we can grapple it with success, and then we shall have to join the two lengths of cable, and put it through again. The third cable—the Trinidad-Demerara section—has been again interrupted. It has been interrupted twelve times since 1879. It lies in shallow water; but it appears that there is something in the composition of the mud on that coast that is poured from the Rivers Essequibo and Oronoco that has a deleterious effect on the iron wires of the cable. That cable has been there for 15 years, and it seems to be going the way of all flesh. We have, therefore, made some proposals to the Government of British Guiana for replacing that cable with a new one of some improved construction to protect the iron wires from the effects of the mud in which that cable lies. We have not yet received any decision from the Government there, and it would not be advisable to discuss the proposals at present. But I hope we shall be able to lay a new cable there without, at any rate, very great sacrifice of revenue to the Company. The concluding part of this report is perhaps the most important one that I have to touch upon to-day. Of all the companies I ever knew there is none whose position so constantly fulfils the idea of being between the devil and the deep sea as the West India and Panama Company. I have given you instances of the disadvantages which the deep sea on the ground where we work causes us. The other unpleasant neighbour assumes various forms. Sometimes it is a promoter with a wild scheme to connect islands where there is no traffic. On that matter we have had some revelations lately. I daresay you saw a case in the papers where some gentlemen had proposed a cable in those regions, and the preliminary proceedings in connection with it were the cause of an action in the courts of law. However, it remains with the public whether these things are subscribed for. The promoters get a profit and leave the public to fish for themselves, after they have made the cable, in very deep water and with very small traffic. I think, after our experience in that part of the world, where there is very small business, and where the water is very inimical to the conditions of telegraphic working, it is not at all encouraging to subscriptions being got from the public. But the new enemy we have is our own Government now. The history of this scheme, that was made the subject of an advertisement, as stated in our report, is as follows:—In the year 1882 there was a telegraph conference at Barbadoes. Representatives from the various West India colonies met there and decided that it would be expedient for them to have a direct line of communication to Halifax, Nova Scotia. They thought by doing that they would be able to get cheaper rates for their messages to England. I do not know how they expected that, because if the enterprise were conducted on commercial principles, there is no doubt that a cable all the way along the coast of America merely carrying the West India traffic, which is very small, would not be worked at so low a tariff as the land lines of America, which are supported by the

Digitized by Google

traffic of the population through which those lines pass. They thought that it would be a nice thing to have a direct line, probably at the expense of the English Government. The matter was put before the Government, and the late Mr. Fawcett reportedly adversely upon it, and very fairly said that the West India and Panama Company would have very just cause of complaint if the Government subsidised a new line. He was then Postmaster-General. The next time we heard of this was that the same scheme was advised by a Royal Commission that was sent out to investigate West Indian finances and West Indian affairs in 1884, and that Royal Commission advocated this scheme. Those who were shareholders at that time may remember that we appended a notice about it in our report. The report of the Royal Commission came into our hands after our report was printed in 1884, and we appended a notice of what they said, and our objections to the scheme. We heard nothing more of it then, until this advertisement appeared last November. It seemed curious that the Government of the day, that was so much interested and so alarmed at the depression of trade and industry at the time, should with a light heart have advised a scheme by which about two millions of English capital were to be almost ruined, because I conclude that the Cuba Company would be very great sufferers as well as ourselves if this line were established. It seems curious that a Government which went out of their way rather in appointing a commission to inquire into that subject should at the same time have adopted a scheme that would so plainly depress a very large amount of capital, and also impair very much the power of this Company to maintain the West Indian connections, which extend all down the Antilles. If our revenue is to be taken from us, how is our Company to keep up the connections with Demerara, Barbadoes, and other important colonies? We have laid our views and objections before the Government, and we have heard nothing of the matter since. I hope the subject may be allowed to drop; but we never feel safe, as one does not know what Parliament may advise. I trust, if such a scheme does come forward, the public will be very careful how they subscribe to it. The water through which the cable will have to pass is deeper than any we have to deal with. It was referred to by the "Challenger" expedition as the deepest in the world. They could hardly get bottom with all their appliances for sounding. In making these remarks about this particular line, I am not saying anything about the expediency of a cable from Halifax to Bermuda, where there is no cable. Bermuda is a great naval station, and no doubt it is a praiseworthy thing for the Government to try and establish telegraphic communication with such an important spot as that. But as to Jamaica, there are three cables already there. No doubt the reason for proposing this step is the idea of having solely British connections with their naval stations and garrisons. But when we have such stations as Aden, Gibraltar, Malta, India itself, and our Australian colonies, all dependent to some extent on foreign communications, it seems strange that they should go out of their way to deal with this matter in the manner I have referred to. It seems rather strange to tell the English taxpayers to promote a line that will do so much damage to existing British capital. I now move:—"That the Directors' report and accounts to the 31st December, 1885, submitted to this meeting be and the same are hereby received and adopted, and that, as recommended by the Board, a dividend of 6s. a share on account of arrears of dividend on the first preference shares be and the same is hereby declared."

Mr. Wm. Ford seconded the motion.

Mr. W. Griffith said he was sure that the appeal which the Chairman had made to the public was one that commended itself to every well-principled mind. The competition which would inevitably result from the new cable to which reference had been made would be to the disadvantage of the Company without benefiting the Government. Why they should not transmit the messages for the Government he could not see. If the Government were to lay down the new cable the result would be that their system would be ruined; but though the Government might be able to send their messages to Bermuda and Jamaica they would be unable to forward messages to any of the other West India Islands. Looking at the matter commercially the distance from Bermuda to Jamaica was so great, the depth of water was so great, that when an accident occurred they would be unable to send any of their messages, and in that case they would be in a worse state than at present. That any high minded man—such as the nobleman who presided over the late Government—should have condescended to propose to enter into competition with two private companies was almost incredible. Fortunately that party was not in power at present [laughter]. He thought, both on commercial and constitutional grounds, the Government ought to abstain from doing that which would ruin the Company and be of no great advantage to the people at large, but rather the reverse. The Chairman had stated that it was the intention to lay down a new line at the extremity of their system, the Trinidad-Demerara cable having become almost useless. If the Government were to step in and help them in that they would help the Company and the naval service. He trusted that in carrying out that cable the Directors would exercise their usual ability, and consider fully the interests of the shareholders, for it must be remembered that that part of the line was quite at the extremity of the Company's system, and that it did not assist them much in the carrying of messages. It was, as he had said, quite at the end of their system, and, therefore, if British Guiana hoped to derive any benefit from it, it was their duty to come forward and assist the Company in assisting them. They were much indebted to the Directors. With 22 stations to command, and with the constant breaks which they heard of, it could not be very easy to manage such a Company as theirs, and they ought, he thought, to tender their thanks to the Board and to assure them that they would have the shareholders' support in resisting any such unconstitutional proceeding as that of high-handed conduct on the part of the Government to injure a private company.

Mr. William Abbott thought that the last speaker's political zeal had outrun his discretion. He did not think it was the Postmaster-General of the late Government that had desired to inflict such an act of spoliation upon them, but the Postmaster-General of the present Government.

The Chairman: No, it was the last Government.

Mr. William Abbott, continuing, said that that being so he was filled with humiliation, because he had thought the late Government respected the rights of property in a marked degree compared with the present Government.

Mr. Ford observed that it was never a question for the Cabinet. It was merely a question of departmental detail.

Mr. Abbott thought that every meeting of shareholders should express their abhorrence at these constant raids on the rights of property—he did not care whether by the present or the late Government. The first raid was on land, then on shipping, then on railways, ground rents, and consols.

Mr. Ford: And the coinage.

Mr. Abbott: And the coinage. When these things were occurring every day, and meetings were called to denounce such conduct towards the rights of property, it was only proper for shareholders in telegraph companies to be up and doing in the same way. They saw the fearful contest that was now going on in the Atlantic, the messages being carried at 6d. per word, and he did not think the commercial interest could complain. Surely the commercial interests of the West Indian Islands could not complain; they had not suffered as the Company had. As to the idea of laying a line from the West India Islands to Halifax, it was a monstrous absurdity, but it was very proper that a monstrous absurdity should be exposed at a meeting of that kind so as to warn those who might be induced to subscribe to it. There was quite enough suffering in their Company from what they had done for the West India islands, and it was their duty to warn those who might be induced to subscribe further money to an enterprise of this kind that they would do so with the certainty of loss. In looking down the balance-sheet and accounts, he must say that they had treated the revenue account with every care and consideration, and he could not find any fault with any of the charges to its debit. Some said that such such an amount should be reduced, but, considering the difficulties they had had to contend against, and keeping up a large staff of men in an unhealthy climate, he must say that he had looked into the report with perfect satisfaction, though he had at first felt disposed, in the interest of those he represented, to cavil at some of the items.

The resolution was carried unanimously.

On the motion of the Chairman, seconded by Mr. William Andrews, Mr. Henry Holmes was re-elected to his seat at the Board; as was also Mr. Henry Weaver, on the motion of the Chairman, seconded by Mr. Ford.

Mr. Griffith then proposed the re-election of Mr. John George Griffiths as auditor of the Company, observing that that gentleman had served them for a long time. As Mr. Abbott had remarked, everything was clear and open, and it was to the advantage of the Company that Mr. Griffiths should be re-elected.

The motion was seconded and carried unanimously.

Mr. Abbott then proposed a vote of thanks to the Chairman and Directors for their services in the past half year. The Chairman had remarked that it seemed strange that the Government should propose to subsidise a rival line. The Government was said to be economical; and therefore, why did they not give the subsidy to the West India and Panama Company? The administration of the money would be very much more economical, and they would get an efficient service against a doubtful one. He wished to give the Directors a word of admonition, as they would not meet again for six months. British colonists were always greedy.

Mr. J. Newton seconded the motion, which was carried unanimously.

The Chairman: On the part of my colleagues and myself I am very much obliged to you for the cordial vote you have given us. I quite recognise the justice and force of Mr. Abbott's remarks, and I hope they will go further, and that people will see that it is not to their interest and the interest of other capitalists in this country to put their money into wild competing schemes merely for the benefit of promoters and people of that class.

The proceedings then terminated.

Telephone Company of Egypt (Limited).

An extraordinary general meeting of the members of this Company was held on the 25th May, at the offices of the Company, 14, Austinfriars, E.C., General Alexander Fraser, C.B., R.E., presiding.

The Chairman proposed and a Shareholder seconded the following resolutions, which were unanimously carried:—

1. That Article 29 of the Articles of Association of the Company be altered by the addition of the following words:—"Provided that no shares shall be allotted at a discount, or on or subject to any special terms or conditions without the previous consent of a meeting of the Company."

2. That Article 56 be rescinded, and the following be adopted in its place:—"The number of Directors shall never be less than three, or more than seven. The directors may at any time, and from time to time, appoint any other persons to be directors, but so that the total number of the directors shall not be more than seven. The continuing directors may act, notwithstanding any vacancies in their body."

3. That Article 58 be rescinded, and the following be adopted in its place:—"The remuneration of the directors shall not exceed the sum of £800 per annum, but the actual amounts to be paid them shall be settled and determined each year by the shareholders in general meeting for the ensuing year, and such remuneration shall be divisible amongst them as they may themselves determine."

4. That Article 60, Clause (a), be altered by the addition of the following words:—"Provided that the total amount for the time being owing

Digitized by Google

shall not, without the previous consent of a general meeting of the Company, exceed £5,000."

To insert the following words in Clause (*c*) of the same Article after "they may":—"With the previous sanction of a general meeting." That Clause (*d*) of the same article be rescinded and the following substituted:—"They may from time to time appoint any one or more of their number Managing Director or Managing Directors, with such share or proportion of the remuneration payable for the time being under Article 58, and for such period as they deem fit." To insert in Clause (*e*) the following words after "grant him":—"Subject to confirmation of a general meeting." To insert in Clause (*f*) after the words "they may":—"Subject to the limitations imposed by paragraph (*a*) of this article" And to add the following words at the end of the same clause:—"And every bill, promissory note, cheque, or other negotiable instrument drawn, made or accepted, shall be signed by two Directors, and countersigned by the secretary or other officer of the Company appointed by the Board." To cancel altogether Clause (*j*) of the same Article (60).

5. That Article (63) be rescinded, and the following be adopted in its place:—"No contract or arrangement entered into by or on behalf of the Company with any company, corporation, or partnership, of or in which any director shall be a member or otherwise interested, shall be avoided, nor shall any director being such member or so interested be liable to account to the Company for any profit realised by any such contract or arrangement by reason only of such director holding such office, or of the fiduciary relation thereby established; but no director shall vote in respect of any such contract or arrangement."

6. To omit from Article 82 the word "cumulative." The clause to read thus:—"First.—To the payment of a preferential dividend at the rate of £7. 10s. per cent. per annum on the capital paid up on the preferred shares."

London Platino-Brazilian Telegraph Company (Limited).

Report of the Directors for the twelve months ended March 31 last to be presented to the eighth ordinary general meeting of the shareholders to be held at the offices of the Company, 50, Old Broad-street, E C., on Monday, May 31st at noon.

The net revenue of the year, after providing for debenture interest and income tax, is £4,087. 18s. 5d., and £1,068. 4s. 11d. is brought in from the preceding year's account, making a total of £5,156. 3s. 4d. to the credit of revenue account. The interim dividend of 1s. per share, paid on the 17th November, 1885, absorbed £1,917. 8s., leaving therefore to be dealt with £3,238. 15s. 4d., from which the Directors propose to appropriate £150 in further reduction of the item of expenses of issue of the 6 per cent. debentures, and £1,917. 8s. in payment of a final dividend of 1s. per share, making, with the interim dividend already paid, a distribution at the rate of 1 per cent. per annum; leaving a balance of £1,171. 7s. 4d. to be carried forward against the amount due by the Uruguay Government. The competition for South American traffic with the cables of the North Atlantic and of the West Coast of America companies has continued during the past year, and has seriously diminished the revenue of the Western and Brazilian Company, in which this Company is so largely interested. The claim of this Company against the Western and Brazilian Company, referred to in previous reports, remains unsettled. The revenue from our land lines shows only a small increase over that of 1884, but from the beginning of the current year there has been considerable improvement in the traffic. The Company's lines are in good working order. According to the Articles of Association, John Pender. Esq., a Director of the Company, retires by rotation, and offers himself for re-election.

West Coast of America Telegraph Company (Limited).

Report of the Directors to be submitted to the ninth ordinary general meeting of the shareholders at the offices of the Company, 50, Old Broad-street, E.C., on Wednesday, the 2nd June at one o'clock p.m.

The accounts for the year ended the 31st December, 1885, show a gross revenue of £45,957. 10s. 10d. against £52,011. 10s. 7d., earned in the previous year. After deducting debenture interest and all other charges, there remains a net balance of profit of £12,890. 12s. 2d., making together with £349. 1s. 3d. brought forward from the previous year £13,239. 13s. 5d. out of which the following dividends have been paid:—

In June, 1885	2s. per share,	£3,000
In January, 1886	3s. ,,	4,500
		£7,500

leaving an available balance of £5,739. 13s. 5d.; of this amount the Board recommend an addition of £5,000 to the reserve fund, which will then amount to £15,000, carrying forward £739. 13s. 5d. The unfortunate war between Chili and Peru, which happily is now at an end, has seriously affected the earnings of the Company, and the general exhaustion caused by that protracted struggle will doubtless be felt for some time to come. However, there appear to be already some signs of improvement in the trade on the West Coast, and with the establishment of a more stable Government in Peru a gradual increase in traffic may be expected. The working expenses of the Company show little variation from those in the previous year. Both cables and the repairing steamer are kept in perfect working order. With great regret the Directors have to announce the loss of the valuable services of their late Chairman, Mr. Robinson Kendal, who died very suddenly on March 13 last. The Board has appointed in his place Mr. Alfred Marshall, formerly partner of the firm of Messrs. Frederick Huth, Grüning, and Co., of Valparaiso and Lima, who has been for many years a resident on the West Coast. The members of the Board retiring by rotation are Mr. Henry Roberts and Mr. Alfred Marshall, both of whom, being eligible, offer themselves for re-election. The auditor, Mr. J. Weise, of Messrs. Turquand, Youngs, and Co., retires, and is eligible for re-election.

BUSINESS NOTICES.—We are asked by the Stanhope Company (Limited) to notify that, under the authority of the Board of Trade, the name of Cordner, Allen and Company (Limited), of 20, Bucklesbury, E.C., has been changed to the Stanhope Company (Limited), by which name the Company will henceforth be known. Mr. W. J. Cordner has retired from the Company, the present Directors being Messrs. James Ashworth, T. M. Collet, and John S. Sawrey.—The business of the Signal Engineering Company is transferred to 26, Red Lion-square, Holborn, where the company carries on the manufacture of telephones and electrical apparatus under the name and style of the Electric Telephone Company.

REMOVAL.—On June 15 the Edison and Swan United Electric Light Company (Limited) remove their offices from 57, Holborn-viaduct, E.C., to 14, Albert-mansions, Victoria-street, Westminster, S.W.

CRICKET.

EASTERN TELEGRAPH COMPANY (LIMITED) *v.* SUBMARINE TELEGRAPH COMPANY (LIMITED).

This match, which has been on the tapis for the past few weeks, came off successfully on Saturday last, on the ground of the Walham Green Cricket Club, Beaufort House, Fulham. The result was a disastrous one for the Continental Company.

The captain of the Eastern Company's Eleven, having won the toss, sent in the Submarine to the bowling of Messrs. McMillan and A. Jack. A very poor stand was made, only two out of the eleven making runs. This was mainly due to the very fine bowling of McMillan, who took eight wickets at a cost of 2 runs, a really splendid performance. The innings closed for 6. Play was resumed after a short interval, the Eastern Company sending in Messrs. McMillan and A. Jack. An unfortunate start was made, A. Jack being caught by Froome for 3. On Cowper joining McMillan, the score was quickly carried to 48, when McMillan, in reaching out to a ball from Muzio, was caught by Frome at point. Two wickets for 48. Macdonald joined Cowper, and the score again rose rapidly, but after scoring 8 the former was cleaned bowled by Kennett. Three wickets for 80. G. C. Jack (captain) followed next, and the bowling, which was getting weak, was completely mastered. Several changes were tried but with no effect, and it was not until the score had reached 128 that a separation took place, a ball from Kennett sending Jack back for a useful 22. Cowper, who had been playing in splendid style, was now joined by Porter, and the score was soon rattled up to 141, when a ball from Cross beat and sent back Cowper for 73. Going in with one wicket down for 6, Cowper, after nearly two hours' play, was out with the score at 141, his fine innings including 1 four, 5 threes, 17 twos, and 20 singles. Payne followed, but after making a single, played a ball on to his wicket. Palmer joined Porter, but with the score at 147 the latter was caught and bowled by Kennett for a careful 11. At this stage of the game "Time!" was called, Palmer carrying out his bat for 3, leaving the Eastern Telegraph Company winners by 141 runs with 3 more wickets to fall. Below will be found the full score:—

Messrs. Richardson, Munro, and Hensman did not bat.

We sincerely hope this will not be the last match we shall have the pleasure of reporting this season between the kindred cable companies. Meetings such as these tend greatly to promote feelings of good fellowship, and the Submarine Telegraph Company are to be congratulated on having been the ones to originate this the first meeting.

DOMESTIC, FACTORY, AND SHIP INSTALLATIONS

Digitized by Google

NOTES.

WENTWORTH CASTLE.—This mansion is now illuminated by 600 incandescent lamps.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 28th May amounted to £2,823.

MANCHESTER.—Messrs. Lewis and Co., it is stated, are about to extend their electric lighting, and to adopt it at their premises in Manchester.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for May amounted to £50,741, against £61,327 in the corresponding period of 1885.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of May are £1,688, against £1,352 in the corresponding period of last year.

CAPE COLONY.—The telegraph receipts for the month of March, 1886, were only £3,000, as against £4,584 in the corresponding month of 1885, showing a decrease of over £1,500.

BELGIAN SOCIETY OF ELECTRICIANS.—At the last monthly meeting of the Belgian Society of Electricians, M. Montefiore was unanimously elected *président d'honneur*, in place of the late M. Melsens.

TASMANIA.—New Post and Telegraph Offices are to be built at Oatlands, at a cost of £1,435. The work is undertaken by Mr. J. Hogan. The building is of freestone, with a front office of 27ft. by 15ft.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of May amounted to £41,037, and to £50,016 in the corresponding period of 1885.

A CATHEDRAL STRUCK BY LIGHTNING.—A terrific thunderstorm broke over Hereford on Wednesday night. The lightning struck the tower of the cathedral, doing great damage to one of the pinnacles and to the roof of the building.

THE ELECTRIC LIGHT FOR PRINTING OFFICES.—The Electrical Power Storage Company has just completed the extension of the electric light to the printing department of Lloyd's, and the absence of heat is much appreciated.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 28th May were £2,284, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE FORBES THERMOPILE GALVANOMETER.—We are informed that Messrs. Nalder Bros. have been appointed by Prof. Forbes the sole manufacturer of his combined thermopile and galvanometer, a description of which appeared in our issue of March 19 last.

BRISTOL.—At the Bath and West of England Show, which opened on Wednesday last on Durdham Down, in addition to the usual telegraphic communication, there is also telephonic communication to the town, the charge being 2d. for a certain time in using the instrument.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 31st May are £2,988, as compared with £3,862 in the corresponding period of 1885. The February receipts, estimated at £5,034, realised £5,098.

FIRE APPLIANCES AT THE EDINBURGH EXHIBITION.—The fire brigade stations within the Exhibition buildings were originally connected by means of mechanical telephones, but this, having been found unsatisfactory, has been superseded, at the request of the Exhibition Committee, by the National Telephone Company's system of fire alarms.

CRICKET.—In reference to the report of the cricket match between the elevens of the Eastern Telegraph Company and the Submarine Telegraph Company, we are asked to say that the eleven representing the Submarine Company was a "scratch" eleven, selected from the accountant's department exclusively, and not the representative eleven of the club.

THE SIMS TORPEDO.—This torpedo, which has been adopted by the United States, is manœuvred, governed, and exploded by electricity. It carries in an after compartment a long length of cable containing the conductors, by means of one of which the apparatus of propulsion is controlled, by the other the direction. Two powerful electro-magnets are used with the latter.

THE ELECTRIC LIGHT AT THE WEST END.—On the 26th and 29th May the Indian Room at Marlborough House was again lit throughout by the electric light, the installation being, as before, carried out by the Electrical Power Storage Company. They also carried out on the 26th an installation of over 100 lights of 20 candle-power at Dover House, which was repeated on the 29th.

"THE MONTHLY CORRESPONDENT."—It is a great pity that the Madeira editor of this lively little Telegraphic Journal should permit a correspondent to occupy over five columns with a letter on "Home Rule," in which the said correspondent shows utter ignorance of the whole subject. If he would begin to learn, perhaps he might with advantage commence by reading Spencer's essay on the subject of Ireland.

THUNDERSTORM IN A CLEAR SKY.—Captain Anderson, of the British barque "Siddartha," which lately arrived in New York, reported a peculiar thunderstorm on April 27, while on the northern edge of the Gulf Stream. The sky was quite clear at the time, and the sun shining brightly, although there appeared to be a thin mist about the ship. Suddenly there appeared a vivid flash of lightning, accompanied by violent thunder. The compass was caused to vibrate perceptibly for a period of fifteen minutes.

CONFERENCE OF TELEGRAPH CLERKS.—The annual conference of telegraph clerks was held at Swansea on the 29th ult. Twenty-four delegates, representing Birmingham, Manchester, Liverpool, Gloucester, Belfast, Cardiff, Dublin, Newport, Monmouth, Hull, Bristol, Leeds, Swansea, and other places, were present. Several matters connected with the status and interests of the telegraph profession were discussed. Letters were read from a number of members of Parliament expressing sympathy with the movement.

ELECTRIC LIGHTING IN A TOBACCO MANUFACTORY.—Messrs. Mather and Platt have recently completed an installation of 700 lamps in the extensive new tobacco and cigar manufactory of Messrs. W. D. and H. O. Wills, Bristol. The building is lighted throughout by sixteen 20 candle-power Swan lamps, and no gas has been laid on except for heating purposes. Two 500-lamp Edison-Hopkinson dynamos, running at a speed of 700 revolutions per minute, have been supplied for this installation, either of which is capable of maintaining the whole number of lamps usually in use at one time.

PUBLIC PROPERTY.—In a paper by Mr. C. J. Kintner, on "The History of the Electrical Art in the United States Patent

Digitized by Google

Office," read before the Franklin Institute, the author says:—"It is a remarkable fact that by a strange chain of coincidences many of the leading and essential features embodied in successful incandescent and arc lighting and also in dynamo machines to-day are public property. It is only upon comparatively limited patents that existing light corporations are based, and this rightly by virtue of abandonment or public use on the part of the original inventors of these broad features."

LIVERPOOL.—It will be remembered that we mentioned the fact, in connection with the Queen's visit to open the Exhibition at Liverpool, that a telephone line had been laid from the theatre to Newsham House. The judges recently on circuit have utilised this telephonic connection in hearing the performance at the theatre. There is nothing new in the transmission of music by telephone, but if the system ever came into extensive use, it seems to us that the managers of the various theatres might very well exact a small charge for every telephone so connected. This might add somewhat to their revenue.

FURTHER PROGRESS.—It is well understood that the future of the telephone is very great, but we hardly supposed that it would have found favour in athletics. At the Darlington athletic sports, however, we notice that there was a telephonic apparatus between the dressing tent of the competitors and the centre of the field, from whence announcements were made of the competitors who were going to run. A Byng acoustic telephone and an electric bell were fitted up by Mr. E. Cox-Walker. In all probability we shall next have an underground series of wires radiating from the popping crease at Lord's and the Oval so that those interested in cricket may hear when their respective champions make good hits.

ELECTRICITY AND LIGHT.—According to *L'Elettricità*, MM. Aubel and Spring have lately been making investigations in connection with the relations between electricity and light. M. Aubel had suggested that we ought to have the same phenomenon with a dielectric in a magnetic field as with the conductor in Hall's phenomenon—that is, we ought to have a rotation of the equipotential surfaces or lines, and, therefore, of the force lines and polarisation in the dielectric. To see whether this was the case, he made use of sulphur, whose specific magnetic power is greater than that of glass, formerly employed by Hall in a similar investigation. He failed to obtain any result, however much he increased or varied the field.

SPANISH COLONIAL TELEGRAPHS.—Spanish advices report the holding of a meeting in Madrid of deputies and senators from Puerto Rico, with a view to concerted action in pressing upon the Government the necessity of various measures required in the interests of that colony. One of these subjects was the question of a direct telegraph cable to the Antilles. A committee was appointed to wait upon the Minister for the Colonies with the request that he would facilitate by every means in his power the proposal of the Canary Company to lay a cable between the Canary Islands and the Spanish Antilles. It was also decided to invite the co-operation of the Cuban representatives in securing a direct cable as the only means of obtaining a reduction in the high prices now paid for telegrams to Europe.

PHILIPP REIS'S TELEPHONE.—A large number of German publications, says M. W. Van Benthuysen in the *Scientific American*, printed from 1860 to 1865, "contain accounts of the transmission of the words and articulate speech by Philipp Reis with electricity, and the instruments as made by Reis do now transmit and receive articulate speech clearly and distinctly, and I maintain that if only five words were so transmitted the discovery of its being done with electricity by Philipp Reis is conclusive, and that no honest or intelligent person can concede to Bell what was done and given to the world unconditionally fifteen years before by Philipp Reis. All subsequent efforts are merely mechanical improvements, and no honest man acquainted with the subject can dispute the discovery by Philipp Reis."

ELECTRICAL PURIFICATION OF COPPER.—Messrs. Sir Hussey Vivian and Sons, of Swansea, about a month ago purchased from Messrs. Mather and Platt, through the Edison and Swan Company, one of the largest dynamos hitherto constructed for electrolytic purposes. It has an output of 50 volts, 1,000 amperes, at 400 revolutions. The weight of the entire machine is $5\frac{1}{4}$ tons; the magnet limbs are solid forgings, each weighing 22cwt., and are shunt-wound only, each limb having 260lb. of copper wire. The armature is constructed of bars 0·338 square inch area, and has a resistance as low as 0·0016 ohm. The commercial efficiency of the machine is over 93 per cent. This dynamo has given such satisfaction that Messrs. Mather and Platt have recently received an order from the same firm for a second precisely similar machine.

FOLKESTONE EXHIBITION.—The lighting of the Folkestone Exhibition was successfully started on the night preceding the opening of the Exhibition, on which occasion it was run until one o'clock, in order to facilitate the completion of the exhibits. The lighting of the pictures hung in the side galleries by means of double clusters of incandescent lamps was thoroughly successful, the arc lamps also showing to good effect in the high central nave and grounds round the Exhibition. It is proposed to utilise the building, if possible, at the close of the Exhibition as a permanent winter resort, for which doubtless the electric light will be retained. The Electrical Power Storage Company, who undertook the work, have received flattering reports from the Folkestone authorities as to the way in which the work has been carried out.

ELECTRIC BICYCLES.—M. Henri de Graffigny, a member of the French scientific press, has recently been amusing himself with the application of electricity to a bicycle, on which he made several successful journeys. *Electricité*, which gives some interesting details of the experiment, concludes an article by saying that with these machines, when the accumulators are properly charged, one may travel a distance of 300 to 400 kilometres without experiencing the least fatigue, and at a speed equal to that of an ordinary railway train. As our readers know, the experiment is not by any means a new one, having been tried by several gentlemen in this country two or three years ago. The results obtained then were not such as to lead us to share the sanguine views of our contemporary as to the future development and popularity of electricity in this direction.

ELECTRIC MOTORS.—Dr. P. H. Vander Weyde, in a paper on "Some Early Experiences with Electro-motors," read before the New York Electrical Society on May 12th, divides electro-motors into three classes:—1. Soft iron armatures alternately attracted by electro-magnets and *vice versâ*. 2. Steel magnets attracted and repelled by electro-magnets and *vice versâ*. 3. Electro-magnets attracted and repelled by electro-magnets. Each of these three classes may be operated upon the principle of to-and-fro or reciprocating motion, having a crank connection, like the piston movement of the steam engine; or they may be operated upon the rotary principle, which appears to be the most advantageous in the application of electricity to power, especially when the Pacinotti ring principle is used,

Digitized by Google

which has wrought a revolution in motors as well as in dynamos.

MERSEY RAILWAY.—Mr. Fox, in his paper before the Institute of Civil Engineers, stated that the stations on this railway were lighted with gas, he being of the opinion that so long as the smallest uncertainty existed as regards the regularity of electric lighting, the railway company was not justified in employing electricity as a lighting agent, unless, indeed, gas was laid on as a stand by. The installation at Paddington will, perhaps, open the eyes of Mr. Fox as to the capabilities of the electric light, and the confidence it inspires. At this time of day it is too late to talk about the non-certainty of the electric light, because any electrical engineer of repute will as certainly provide against a breakdown as the railway companies do in the case of engines. We maintain that electricity is as certain as gas, and far more safe and pleasant.

METROPOLITAN BOARD OF WORKS.—In the report of the Metropolitan Board of Works for 1885, just issued, some three or four pages of the report are devoted to the consideration of telephone and telegraph wires, stating at some length the position of the Board of Works in relation to these matters, and the suggestions of the Select Committee after having taken evidence. We have already commented upon some of the absurd suggestions made, and especially that which would give permission to pass wires over property without the owners or occupiers having the right of prohibition. This report concludes: "It is now, apparently, for the Government to consider whether the Legislature shall be asked to pass a Bill framed in accordance with the suggestions of the Select Committee." We are strongly of opinion that no Government that has existed—or ever will exist—will be able to pass a Bill containing these suggestions, several of which are altogether in opposition to the general tenor of legislation.

DIELECTRIC CAPACITY.—Some experiments on the dielectric capacity of gases at 0° C. and 760 mm. have lately been made by Klemencic, who gives the following table. The corresponding table of refractive indices are those determined by M. Mascart:—

	$\sqrt{K}$ (K = specific inductive capacity).	μ (= refractive index).
Air	1·000293	1·0001927
Hydrogen	132	1387
Carbonic acid	492	4544
Carbonic oxide	347	5350
Protoxide of nitrogen	579	5159
Ethyline	728	7200
Sulphuret of carbon	145	1478
Sulphurous acid	477	7040
Ether	372	1537
Chlorethyle	766	1674
Bromethyle	773	1216

It can be seen that for the last four gases the square root of the specific inductive capacity is no longer comparable to the index of refraction.

TELEPHONY.—We take the following from our American contemporary the *Electrical World*. When the instruments and experimentalists reach Liverpool we may have something further to say on the matter:—"The following is the account given by a Cleveland despatch of a recent telephone test between that city and New York: A public telephone test was given this afternoon between this city and New York by Count Mitkiewicz, representing a Baltimore invention. The wires were made up so as to make as long a distance as possible, and covered a circuit of 1,600 miles. A very large and select party of capitalists, &c, witnessed the test, a special feature of which was the singing of Miss Emma Abbott and Miss Bellina, of the Abbott Opera Company, both of whom were interested witnesses of the test. Seven receivers were attached at one time, so that that number of persons could hear at the same time. Songs were also sung by the parties at New York, all of which were most distinctly heard by every one at this end. A test across the Atlantic Ocean will be made as soon as the parties, who are now on their way, reach Liverpool with the instruments."

THE ALBERT PALACE, BATTERSEA.—The electric lighting for the Albert Palace is to be on an extensive scale. A large open-air theatre is being erected in the grounds in imitation of the Cafés Chantants of Paris, and among other attractions there will be a ballet. The front of the proscenium is to be illuminated by a double row of incandescent lamps, while a powerful arc light is to be placed on the top of the band stand opposite to, and directed on, to the stage. A number of tall venetian masts are to be placed in the grounds, having an arc lamp on the top of each, while from post to post and thence to the top of the band stand thousands of coloured incandescent lamps are to be suspended in festoons. The interior of the palace itself will be lighted during the summer months with arc lamps, to which are to be added some two thousand incandescent lamps during the winter when the outdoor attractions are over. A new and capacious engine house is in course of erection, and the Jablochkoff and General Electricity Company, who have taken the contract for the lighting, have arranged with Messrs. Hornsby and Sons to supply two powerful steam engines with all their latest improvements.

BLUNDERING WITH DYNAMOS.—The following appears in the *Machinery Market*, a periodical devoted to "trade," and not to "science." We confess to an utter inability to understand the references. Was the lubricant applied to the bearing or to the "commutator?" The terms are, or seem to be, used by the writer indiscriminately. Yet, the bearing is not the commutator, nor the commutator the bearing:—"It often occurs in establishments supplied for the first time with electric appliances that engineers and others are placed, after a short period of instruction, in charge of dynamos and electric motors. To these men, experienced as they may be in steam engineering, the introduction of electrical terms, and the unfamiliar terms given to machines and their parts are mystifying. In one of our large factories, after the dynamos had run only a few hours, the bearings of the commutator showed signs of heating. Following out the practice pertaining to similar difficulties in the steam engines, the engineer tried the effect of plumbago mixed with lubricating oil. The result might have been expected; the plumbago applied to the commutator being an excellent conductor, a short circuit was formed, rendering it necessary to stop the dynamo until the difficulty was remedied."

SKINNING BY ELECTRICITY.—One of the latest American inventions is an "electric siding-knife," for skinning the carcases of animals without injuring the hides. In the immense slaughtering houses in the United States there is often a rush of business, and unskilled labour is frequently employed in the skinning of oxen and other animals, with the usual result that hides are seriously deteriorated in value by accidental cuts of the knife. As many of these establishments have an electric lighting plant which is lying idle during the day, it occurred to a Mr. Newgass, who has been for many years manager of one of the large canning companies, that the current might be utilised for flaying the animals, and he has accordingly invented a siding-knife, in which a platinum wire is raised to incan-

Digitized by Google

descence by the electric current, and the hides are burnt off, so to speak, instead of being cut off. The preliminary cut is made with the ordinary knife and the butcher then takes the electric tool, in which the incandescent wire is shielded by guards, so that neither the flesh nor the skin is injured, and with long, quick sweeps the hide is separated from the carcase in an expeditious and cleanly manner, and is found to be worth about a cent a pound more than those taken off with the ordinary flaying knife. When the meat is required for freezing and exportation, a further advantage is said to be found, for the incandescent wire, by closing the pores of the flayed surface, preserves the colour of the meat, and the sides of beef and carcases of mutton do not sweat, or "weep," when removed from the chill room, as in the old-fashioned method of skinning. The cost of the current is stated to be more than covered by these advantages, and the little skill necessary for using the electric "sider" is readily attained.

West African Cables.—On May 22nd, the cable ships, the "Dacia" and "Buccaneer," owned by the Silvertown Company, left the Thames, *en route* for the West Coast of Africa, and laden with cable for the continuation from Konakri along the African coast of the West African Telegraph Company's system, which already extends to the French settlement of Konakri. The first work upon which the ships will be engaged is the connecting of Bathurst to the Cape Verde islands, on behalf of the African Direct Telegraph Company. Konakri and Sierra Leone will thus be placed in communication, and the heavy cables for the shore ends at Grand Bassam, Accra, and probably Porto Novo, will afterwards be laid. The ss. "Silvertown" will sail about the end of June, and will lay the main cable between those points at which the "Dacia" will have landed the shore ends. She will then proceed to continue the West African Telegraph Company's system to S. Thomé, Principe, Gaboon, and S. Paulo de Loanda. The Telegraph Construction and Maintenance Company are sending out their "Britannia" and "Scotia" to lay, under contract with the African Direct Telegraph Company, a section between Bathurst and Sierra Leone, thus duplicating the West African Telegraph Company's communications to the latter place. The same firm will then connect Sierra Leone with Accra, and this section will be employed as a common line for the West African Telegraph Company and the African Direct Telegraph Company. From Accra the latter company's cables will be continued on to Lagos, and to the mouths of the River Niger. We are informed that the Colonial Office has conceded an extension of time to the Telegraph Construction and Maintenance Company for the completion of their work, due to the fact that the "Scotia" will require to make two trips. The "Dacia" is reported as having left Lisbon on her way to the coast on May 29, after having received on board the representative of the Portuguese Government. The "Buccaneer" arrived at St. Vincent on June the 1st, and will proceed thence to Bathurst, where she will join company with the "Dacia."

Gas Lighting in Spain.—The Spanish papers still continue to discuss the disputes that have arisen between the consumers of gas and the gas companies in Madrid and in Cadiz. In view of the probable early completion of arrangements for the installation of the electric light by the Edison Company, to which we alluded last week, the Madrid Gas Company has addressed a very polite circular to its customers, in which it expresses its desire to comply with their wishes, and in which it lays all the blame for the present dispute on the committee of the Mercantile Club. In reply to this circular, a member of the club writes to the *Dia* to explain the circumstances of the case, from which it appears that five or six years ago a committee to represent the consumers petitioned the company in favour of a reduction in price and improvement in the quality, upon which the company offered to lower the price of gas when the railway in the coal fields of Asturias should be completed; and further to place a testing apparatus in the Mercantile Club. It is affirmed that the extension of the railway system in the North Eastern provinces has taken place, but that the company has not carried out either of its promises, while the present conditions proposed by the company now are a prolongation of its monopoly for 29 years, in return for a reduction of 10 per cent. now and another 10 per cent. in the space of ten years. These terms have been rejected by the Consumers' Committee, and there is no appearance of the matter being amicably settled. Meanwhile the trading community, headed by the dealers in textile goods, have abstained from the use of gas since the 15th ultimo, and pending some satisfactory arrangement for the introduction of the electric light, are lighting their premises with oil lamps, those most in vogue being apparently the American system known as the "Rochester," and the Vulcan lamp. As regards the conflict in Cadiz between the present French company and the proposed local Spanish company, a committee has left for Madrid to lay the views of the community before the Government. The *Dia* of the 28th May publishes a telegram received by one of the Committee to the following effect:—"The new light by means of electricity and petroleum has been inaugurated amidst indescribable enthusiasm and illuminations, the thoroughfares being crowded by thousands of the population." As the deputation to Madrid is to obtain the cancelment of the order forbidding the formation of a local gas company, it is to be presumed that the electric light referred to is of a private installation, and may or may not be of a permanent character.

Two New Radiophones.—M. Mercadier, in a paper to the *Journal de Physique*, states that all known radiophones may be divided into two classes:—I. Those in which the transformation of radiant energy into mechanical energy, in the form of sound, is effected *directly*. The radiant energy might be that of the heat, the light, or the ultra violet rays, and the apparatus might be respectively termed thermo-, photo-, and actino-phone. We have examples of the former two, but not of the last. II. Those in which the above-mentioned transformation is *indirect*, and there are one or more intermediate transformations. The photophone of M. G. Bell is of this kind, and in this the intermittent radiations act on a layer of selenium, of alloys of selenium and tellurium, or of lamp-black, placed in a circuit containing a battery and a telephone. In this case it is known that it is principally the luminous radiations which act, producing in the circuit variations of electrical energy, whence result the sounds in the receiving telephone. Such instruments might be called photo-electrophones. The author says he has invented two new kinds of indirect radiophones of the thermic kind. First, he has shown that a microphone is sensitive for the action of intermittent radiations. It is sufficient to take an instrument of this kind where the supports of the carbons are fixed to a thin plate or diaphragm of varnished deal and united to a receiving telephone, either with or without an induction coil in the circuit of the battery. By exposing the diaphragm to the action of intense radiations, which are rendered intermittent (for example, by means of a wheel with holes in it), sounds are heard in the telephone whose pitch varies in a continuous manner with the velocity of the wheel. Secondly, he has shown that any transmitting telephone is equally sensitive for the same

Digitized by Google

action produced on the iron diaphragm. The sounds produced are much the same as in the former case. In both cases the diaphragm of unpolished deal or iron ought of necessity to vibrate in absorbing superficially the thermic radiations (perhaps in the case of the iron the magnetic properties also may be affected by the warmth). They may be called thermophones. The first might be called a thermo-electrophone, the second a thermo-magnetophone. The effect may be intensified—(1) By smoking the surface of the wooden or iron diaphragm; (2) by confining a layer of air in front of the smoked diaphragm by means of a piece of glass or mica; (3) by augmenting the intensity of the source of light. They are feeble, with the oxyhydrogen light, but are strong with electric, and still more with solar light.

CHOICE OF METALS FOR CONDUCTORS.—M. E. Bède, lecturing the other evening before the Belgian Society of Electricians on the choice of metals for the wires of telegraph and telephone lines, observed that since the achievements of M. Van Rysselberghe, telegraph lines must not be considered separately from telephone lines. M. Eric Gérard, in his recent lecture before the Society at the Montefiore Electro-Technical Institute, pointed out that in accordance with Hughes' experiments in self-induction, and those which he himself had conducted at the Electro-Technical Institute, that to transmit equally for an alternating current with very short undulations, like telephone currents, iron wires must be employed of a slightly larger diameter than that of a copper or phosphor bronze wire of high conductivity. Consequently, the weights of the two lines in iron and in phosphor bronze—equally good for telephonic transmission—would be in the ratio of 32 to 1, and as the price of galvanised iron wire is more than one-eighth that of the bronze, it follows that a line laid with iron wire would cost at least four times the amount of an equally good line in phosphor bronze wire of high conductivity, without taking into consideration the fact that, being thirty-two times heavier, it would require much more costly supports and labour. From the beginning of telephone exchanges M. Bède had adopted for the wires the phosphor bronze of M. Montefiore, and the results had always been excellent. Now almost all the telephone companies had followed this example, and it had been found possible, with phosphor bronze wire of great tenacity, to span whole valleys of 800 metres (875 yards) without intermediate supports. After M. Bède's lecture, M. Banneux, Inspector of the Belgian State telegraphs, declared that this Administration has decided to replace all the iron wire lines as they became defective by those of phosphor bronze, and had already given some large orders to M. Montefiore. M. Van Rysselberghe then declared that, judging by his experience in America, it was not possible to establish good telephonic transmission to long distances by means of iron wires, while with those of copper excellent results were obtained. It was thus that he was not able to correspond properly at a distance of 250 miles by means of iron wire of 4½ mm. diameter (No. 8), while he corresponded perfectly well from New York to Fostoria, a distance of 730 miles, with a hard copper wire of 2·7 millimetres, and from New York to Chicago (1,010 miles) with a compound wire, formed with a steel core of three millimetres, surrounded by a thickness of 1·5 mm. of copper, corresponding to a 5 mm. copper wire. It was certain that communication could be established by telephone with such a wire at 2,000 miles distance, so as to give commercially satisfactory results.

MEETING OF TELEGRAPH BOYS IN PARIS.—It is not often that we have a ludicrous side to telegraphy, at any rate so far as the messenger boys are concerned; but the correspondent of the *Daily News* at Paris has given matter for a good laugh, if for nothing else, and at least two daily papers have thought the matter sufficiently interesting to have leaders upon it. We give the *Daily News* account, and wonder whether China has not imposed her civilisation upon this western land:—"The Liliputian corps attached to the telegraphic service have held their indignation meeting at the Salle Tessier, at Grenelle. Only a single boy in active service went in uniform, and he had the collar bearing his number turned down to hide it. To the great concern of the poor little fellow, Johne, the leader of the movement, insisted upon his acting like a man and showing the whole of his collar. The other youths who came to air their grievances were in plain clothes. There were a good many others who had been turned off for letting Johne persuade them to strike. He is now a printer's devil. The unfortunate lad in uniform was called to the chair, but proved an honorary chairman, the effective one being the instigator of the strike—the Citizen, or as some termed him *le compagnon* Johne. He looked a singularly self-assured youth. Johne related his experience as a member of the Juvenile or *Petits Bleus* Telegraphic Corps with a seriousness which did not appear to strike his youthful hearers as ludicrous. He complained that the administration and the adult clerks and messengers had not a proper amount of consideration for the dignity of the boys, and treated them with disrespect. They were actually made to take turns in sweeping the offices and lighting the fires, just as if they were not *employés* of the State, and governed by the same laws of advancement as their elders. The grown-up clerks and messengers spent their leisure in paring their nails and jocular conversation, or in writing poetry, novels, and love letters, whereas the boys were not allowed to use pen and ink unless to copy literary extracts by way of punishment. It was here explained that their salaries being too miserable to admit of fines, they had to write out impositions as in school, and there were boys who had often to get through a couple of hundred lines of Corneille, Racine, or some other poet whose works they thought a bore. They were not allowed to play cards or read the journals, although there were always newspapers lying about. If any *bourgeois* made any complaint against them, whether for asking for a gratuity, or being a little late, or showing impatience when rings at door bells were not quickly answered, they were dismissed. Johne was sent about his business for asking a *bourgeois* who offered him a sou, whether he had not more small change than that, and returning to him the copper coin, not that he valued money half so much as dignity. One day he gave a telegram to a foreign prince at the Grand Hotel. His Royal Highness threw him a five-franc piece piece, but with such an air of contempt that Johne on picking it up placed it on the table and said, 'My humble means enable me, Monseigneur, to live without accepting this gratuity.' The young orator wound up by apostrophising *la révolution sociale*, the only revolution that would deliver young telegraphic messengers from their oppressors. This part of his speech was warmly applauded, not only by the juveniles, but by about 100 adults. An Anarchist then demanded *la parole*, which poor little Doucet, the shy chairman, granted him, and he thanked the young for having set a good example to the old. The chairman then rose to address the meeting, but broke down. All he could say was, 'I am not used to public meetings, but trust on some future occasion I shall acquit myself better.' It was then announced that the great Johne was to convoke a monster meeting, and that he and some young compositors whom he knew would print the placards for nothing. He hoped in the meantime that his young friends would think well about what they had to say, so as to be able to defend their cause if orators rose to contradict them."

THE STEAM ENGINE INDICATOR.—XVII.*

BY AMICE.

Having now sufficiently described the principle and mode of action of most of the systems of compound engine in use, we will, in the order in which we described them, deal with indicator diagrams taken from each kind; but we will first take an ideal diagram to show what we should expect to get from a compound engine if made of non-conducting materials, so that there would be no loss of heat by radiation or conduction, and also, supposing that there be no loss of steam in parts or spaces in passing from one cylinder to another. Then the diagrams (Fig. 49) would represent what the indicator would obtain from the two cylinders of an engine without an intermediate receiver. Steam enters the high-pressure cylinder, as shown by the line L B, and is admitted during about two thirds of the stroke, as seen by the line B C. From C to the end of the stroke the piston is moved by the expanding steam, as shown by the line C D. At D exhaust takes place, but instead of the steam passing into the atmosphere and the pressure falling to E, as it would in the simple engine, and be indicated by a line D E, it passes into the second cylinder, and the entrance line F G is drawn by the indicator pencil. As the second cylinder has not an inexhaustible supply of steam, but only that which has come from the high-pressure cylinder, the pressure falls from the moment the piston commences to move, and the whole admission line GH is an expansion line, and is seen, by putting the two diagrams in the relative positions shown in Fig. 49, to be a continuation of the expansion line C D of the high-pressure cylinder.

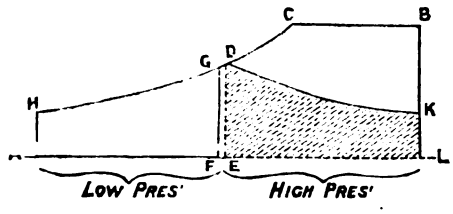

Fig. 49.

Thus far we have looked only at one stroke of the high-pressure piston, namely, that from B to D, and the one stroke of the low-pressure piston from G to H. We have, however, to observe that whilst the low-pressure piston was performing its stroke with pressure varying as represented by the height above A L of the line G H, the high-pressure piston was performing its return stroke with a back pressure, D K, equal to the pressure in the low-pressure cylinder. The back pressure against the high-pressure piston is thus equal to that indicated by the shaded part of the diagram, and only the area included within K B C D represents effective work. Such would be the diagrams under the ideal conditions. In practice, however, all the adverse conditions which we, for purposes of explanation, excepted, come into play, as will be more fully seen hereafter. We have, moreover, for simplicity of explanation, assumed that both the diagrams of Fig. 49 are taken with the same spring, or are of the same scale. This, of course, is not the case in practice, as the spring, which would be stiff enough to give a good diagram from the low-pressure cylinder, would be quite unsuitable and of insufficient strength for the indicator when on high-pressure cylinder.

It is usual with engineers to compare the practical indicator diagrams from compound engines with the theoretical, and with each other, by reducing the length of the high-pressure diagram in proportion to the relation between the area of the high-pressure piston and the low-pressure-piston. By this means the high-pressure diagram may be placed above the low-pressure diagram, as shown in Fig. 50, instead of end to end with both to one scale, as in Fig. 49, and not only is the expansion curve of the high and low-pressure diagrams brought into position for inspection as to the action and behaviour of the steam, but the amount of loss of steam pressure between the two cylinders, as shown by the gap which occurs between them even when they are placed as close as possible. This gap is seen at C, Fig. 50, A and B being the high and low-pressure diagrams. These are, however, diagrams such as would be obtained from an engine with a receiver, while the two diagrams (Fig. 49) are supposed to relate to the theoretical engine without receiver and with cylinders assumed for explanatory purposes to be of the same size. Before following up the method pursued in redrawing actual diagrams for comparing them with each other and with theoretical expansion curves, we will look at a few actual diagrams.

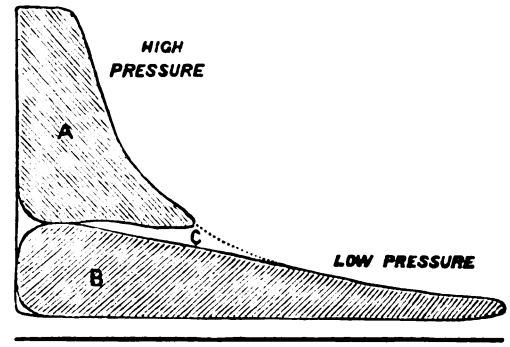

Fig. 50.

Commencing with those from a small engine, we have the diagrams given in Fig. 51. These are from a small vertical tandem condensing engine. The cylinders were respectively 4·5in. and 7in. diameter, the stroke being 10 inches. The two diagrams were taken with different spring, the high-pressure diagram we reproduce being taken with one which compressed $\frac{1}{80}$in. per lb. pressure, or whose scale was 80lbs. to the inch. The engine made 180 revolutions per minute, and at this speed gave 12·53 indicated horse-power. An inspection of these diagrams reveals a very satisfactory division of the work between the two cylinders, but there is a good deal more loss of pressure by the steam in passing between the high and low-pressure cylinders than is necessary, and much of this seems to be due either to restricted passages or to unsatisfactory action of valves, though most of it was no doubt due to condensation in the exterior pipe connecting the low to the high-pressure cylinder and in the latter cylinder itself. It will be seen in both diagrams at A' that the momentum of the indicator parts under the influence

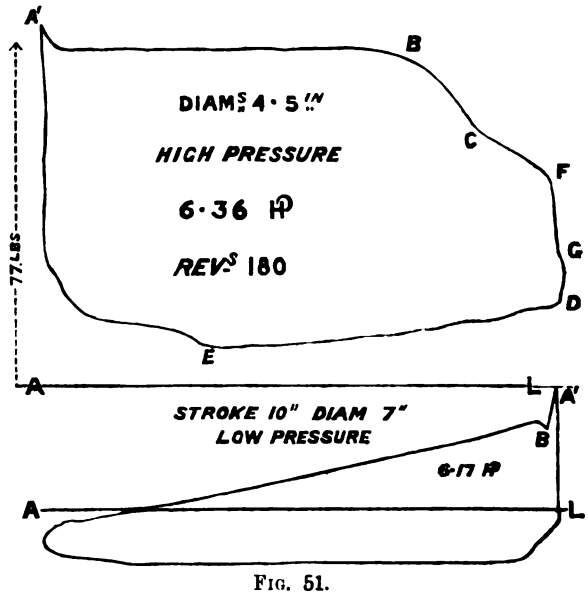

Fig. 51.

of the pressure and speed carried the pencil above the actual pressure, the recoil carrying it down to B in the low-pressure diagram before steadiness was attained. Full steam, it will be seen, was admitted to the high-pressure cylinder during about three fourths of the stroke, cut-off taking place near B, from which point pressure fell very rapidly, but became suddenly checked in its fall at C, probably by re evaporation. Exhaust occurred

* For Art. 16, see *The Electrician* 14th May, 1886.

Digitized by Google

freely at F, except for the slight check at G, probably caused by the low-pressure piston reaching the end of its stroke. From D the pressure falls steadily, though less fast than that in the low-pressure cylinder, until the point E is reached, the valve closes, and compression commences. The relations between the areas of the cylinders being as 15·9 to 38·48, and assuming the cut off to be at about three fourths or 0·75 of the stroke in the high pressure, the actual range of expansion was only about $\frac{38{\cdot}48}{15{\cdot}9} \times 0{\cdot}75$ or 3·2. This is not enough, even in so small an engine, to secure the advantages derivable from the compound system. Such a range of expansion could be at least as economically used in a single cylinder or simple engine.

The diagrams (Fig. 52) are copied from a tracing of the indicator diagrams from a small horizontal tandem engine of the same class, namely, non-receiver class, but the passage between the two cylinders is proportionally much larger than in that from which diagrams (Fig. 51) were taken. It may be remarked that tracings from diagrams are not always exactly like the diagrams. This will be seen hereafter. The cylinders are 7·25 and 13·25 respectively, the stroke being 18in., and the number of revolutions 100 per minute. The steam pressure in the boiler was at the time the diagrams were taken 65lb., or an absolute pressure of 80lb. The maximum pressure in the high-

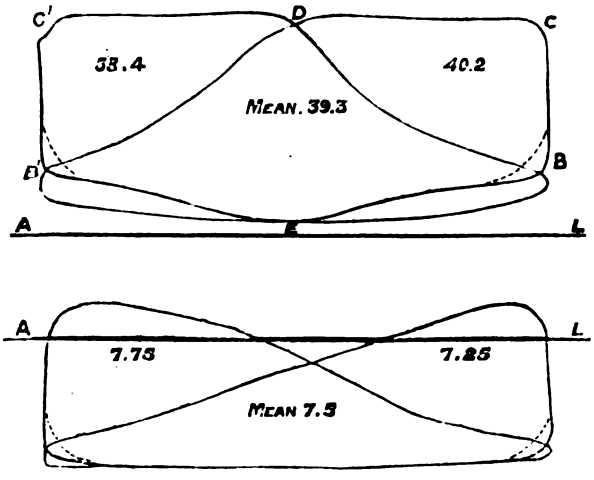

FIG. 52.

pressure cylinder reached 63lb. or 78 absolute. Steam was cut off at about half stroke, and the mean pressure taken from the two high-pressure diagrams is 39·3lb., and the corresponding mean in the low-pressure cylinder is 7·5lb., the pressures at either end of the low-pressure cylinder being more nearly alike than in the high-pressure, although even there the means are not remarkably dissimilar. It will be seen that the slow closing of the valves caused a gradual rise in the back pressure in the high-pressure, as shown by the line from E to B, or E to B'. The indicated horse-power as measured from these diagrams was 13·75 in the high-pressure cylinder, and 9·39 in the low, or a total of 23·14. For satisfactory working the heel B B' of both diagrams should be less sharp. For 100 revolutions per minute, a curve such as shown by dotted lines would have given a better result with this engine. A slight difference in the rapidity of port opening is seen at C and C'.

Figs. 53 are from the same engine working at 90 revolutions per minute, and more cooling water passing through the condenser, thus producing a better vacuum. These diagrams have been more faithfully reproduced. They show better action at the compression end of the stroke, but the improvement is marred by the defective action of the valves and by excess of compression, especially at B. Re-evaporation is plainly seen in the too slow and irregular fall of the high-pressure expansion line. An undesirable difference in the admission and early expansion of the right hand low-pressure diagram is seen at B, and it will be seen that this is accounted for by the shorter periods of admission to that end of the high-pressure cylinder from which the steam came, namely, the left-hand end, as seen at C. In both Figs. 51 and 52 the diagrams were taken to a scale of 30lb. and 8lb. to the inch respectively. We may now take an example from a large compound tandem with no other receiver than that provided by the large pipe connecting the

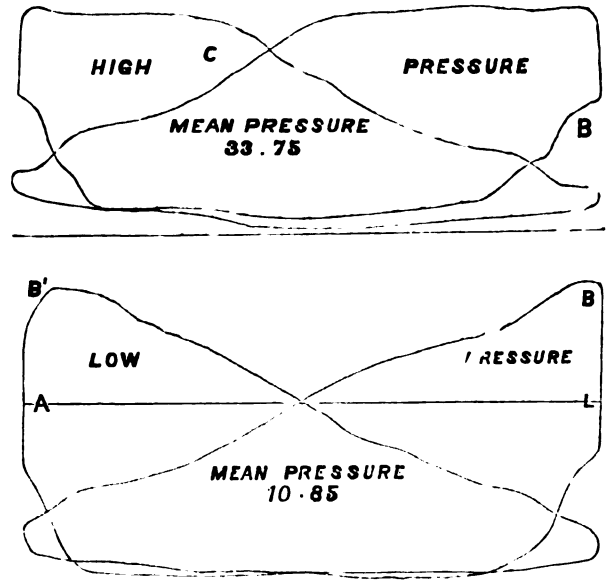

FIG. 53.

two cylinders. The diagrams (Figs. 54 and 55) are the high and low-pressure diagrams from a large horizontal tandem pumping engine, fitted with differential valve gear, and making from ten to eleven strokes per minute. They were taken to scales respectively of 32lb. and 16lb. to the inch, but, like the preceding diagrams, are reduced in size for our purposes. The engine cylinders are 45in. and 72in. respec-

FIG. 54.

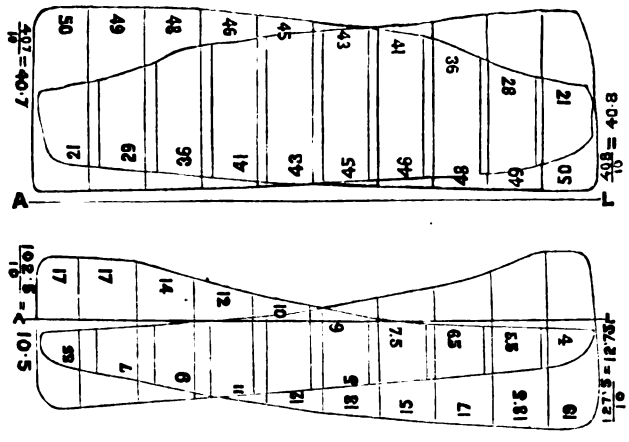

FIG. 55.

tively, and the stroke 9ft. The high-pressure diagrams, of which one pair is here shown, give a mean pressure of 40·75lbs. per square inch, and the area of the cylinders or pistons being 1,590 square inches, we have, with 10 strokes per minute (1,590in. × 40·75lbs. × 90ft.) ÷ 33,000 = 176 horse-power indicated. Two corresponding low-pressure diagrams, taken immediately after, but at a time when the speed had reached 11 strokes per minute, gave a mean pressure of 11·5lbs., and the area of the cylinder being 4,071·51 square inches, we have (4,071in. × 11·5lbs. × 99ft.) ÷ 33,000 = 140 horse-power, or a total of 316 horse-power. It will be seen that these high-pressure diagrams are satisfactory in every respect, except in the restricted admission shown by the right hand diagram; but the low-pressure diagrams show an insufficient capacity in the condenser, the vacuum being but slowly formed, or, rather, very slow in reaching its maximum.

The diagram shown at Fig. 56 is taken from a tandem non-condensing engine of the type shown by Fig. 46. The engine, nominally of 10 horse-power, was tested in comparison with

Digitized by Google

an ordinary 10-horse portable engine by the same makers, and was said to make a very satisfactory performance. Both high and low-pressure diagrams are taken by the same spring, and the arrangement of the engine gives the diagrams in a relative position which permits immediate comparison of the actual area with the total area it would have if there were no gap. That is to say the diagrams are placed with the exhaust end of the high-pressure diagram immediately above the admission end of the low-pressure diagram. Following the steam, we may commence at B with the admission of steam from the boiler with the high-pressure cylinder, the pressure rising to C with but little restriction; full-pressure steam is admitted to D, expansion takes place to E, when exhaust takes place and pressure falls to F, the exhaust passing at pressure F′ into the low-pressure cylinder, wherein the pressure is shown by the line F′ H, while the pressure in the high-pressure cylinder is shown by the line F G, and is higher than that in the low by the amount of the gap between them, the loss of pressure shown by the distance between the lines F G and F′ H being caused by friction through ports and passages and valves. At G the valve closes the high-pressure exhaust and compression takes place from G to B. In a

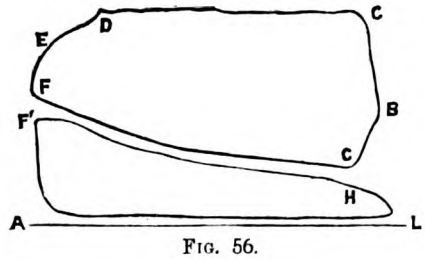

Fig. 56.

trial with the engine of this type, as above alluded to, the compound engine made 18,000 revolutions against a given brake load, the water being maintained at the same level in the boiler as shown by the water gauge, while the non-compound engine made but 15,000 revolutions, and the boiler lost an inch in the level of its water, the same weight of coal being used in both cases. The boiler would thus have been able to continue this rate of work with the compound engine, while the simple engine would soon have had to be stopped, or had some of its load removed to enable the boiler to overtake its water consumption. Moreover, the compound engine boiler was fed with cold water, while the simple engine had a feed heater which raised the water to 150 degrees.

AN IMPROVED REGISTERING APPARATUS FOR THE VELOCITY OF TRAINS.*

In railway travelling we are accustomed to arrive and depart punctually. If the train is delayed the traveller grumbles, unless the driver makes up for lost time by extra speed. He seldom thinks of the dangers that threaten a train going at a too high speed, and yet these are so great that every precaution must be taken to diminish them. There is no perfectly reliable means by which a too high speed may be avoided automatically, and thus the speed depends entirely on the will and attention of the engine driver. He has, indeed, precise directions concerning the allowed speed; but, since he cannot be mechanically hindered from overstepping his instructions, efforts have been made to at least subject their carrying out to exact regulation. This can be done in two ways, either by a self-registering measurer of velocity which is placed on the locomotive, or by means of contact apparatus placed on the railroad, and registering clocks which are set in action by the train itself.

On railroads which are provided with this registering arrangement there is an insulated wire stretched along the line, branching off to the contact apparatus, which, as a rule, are about a kilometre apart. If there is contact made in one of these apparatus, an electric current is sent to the station, and there the moment at which this current is sent is fixed by a registering clock and other appliances. Thus the speed of the train between any two contacts is known.

The contact apparatus usually consists of a set of one or more levers, which project from a box fastened to the track, and reach somewhat over the rail. When a train passes this place its wheels press down the lever, and thus produce the desired contact in the box.

The great difficulty has been to prevent these apparatus from being destroyed by the violent shocks to which they are subjected when a train meets them, but this has been greatly remedied by springs, with which the levers have since been provided. These contacts with springs have been found so useful that up to the end of 1885 more than 1,500 of them had been installed on the German railways.

Still, the contact apparatus with lever movement, despite all the care devoted to its construction, cannot be insured from external damage. Hence, for some time they have been trying to erect contact apparatus whose movable parts are hid, or more especially such as have no movable parts. They have fastened to the rails as contact makers little closed boxes which contain weighted springs, hammers, or quicksilver. When a train passes their inner mechanism is set in motion

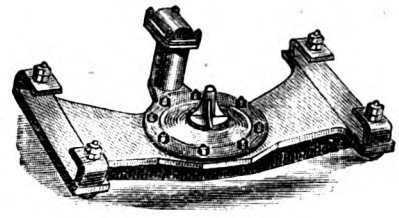

Fig. 1.

by the vibration of the rails, and makes contact by hitting against the corresponding conductors.

A third class of wheel-contacts depends on the bending of the rails against a fixed exterior point, caused by the passage of the train. All these apparatus have their several defects, and contacts are sometimes made without the passage of a train over the corresponding rail.

The firm of Siemens and Halske has lately produced a contact apparatus (Fig. 1), depending upon the bending of the rails, which needs no exterior fixed points, contains no movable lever, and can be made of any desired sensitiveness. That bending is employed which takes place between two points of a rail as soon as this is weighted between these points by a wheel of the train. The strong transfer of movement, which is necessary to insure results with certainty in such an apparatus, is obtained by hydraulic transference of pressure as follows:—

Under the rails a strong cast-iron bent beam $M L L_1 M_1$ (Fig. 2) is firmly screwed by means of the nuts $M M_1$. In the

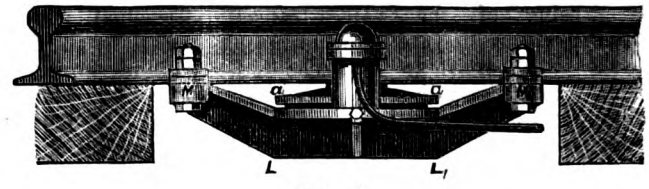

Fig. 2.

centre this beam forms a flat dish (Fig. 3), which is shut in by the spring-steel plate *b b*. On *b b* rests the iron disc *c c*, which is held centrically by the pressure of the plug *d*. The plug is so adjusted that it just touches the rail when the apparatus has been screwed to the latter. On the cover of the dish *a a*, and under the foot of the rail, there is a ring of gutta percha fixed to protect *d* from the penetrating sand which might impede its free action. The vessel G is in connection by the narrow hole and pipe *f f* with the hollow space under the plate *b b*. This pipe widens itself upwards into the cup *r*. As far as the tube projects into the cup it consists of insulating material; *f* communicates with the hollow part of the vessel by the little opening *h*, and there is also a small hole, *s*, in the bottom of the cup.

*From the *Elektrotechnische Zeitschrift* for April, 1886.

Digitized by Google

The space under *b b* and the vessel G are so far filled with quicksilver that the bottom of the cup is just covered. From the difference of level of the quicksilver in G and under the plate *b b*, the plug *d* is always firmly pressed against the foot of the rail by a hydrostatic pressure of about 30 kilograms. If the rail bends a little by a weight passing over it the foot of the rail presses on the plug *d*, and the pressure is communicated by the disc and plate *b b* to the quicksilver, and it soon fills the cup *r*, since the surface of the plate is to the section of the tube as 600 to 1. As soon as the train has passed, the quicksilver runs slowly out of the cup through the hole *s* into the vessel, and thence through the hole *h* again into the space under the steel plate.

Into the bowl *r* and the insulated end of the tube *f* projects the fork *i*, which is connected to an insulated cable. This fork is insulated from the earth except when the mercury reaches it.

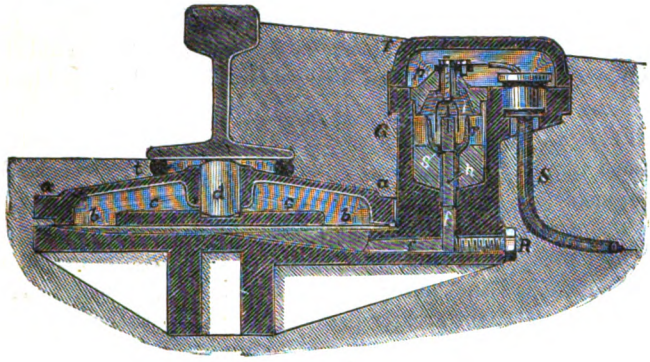

FIG. 3.

All the parts which come in contact with the quicksilver are made of iron, because this metal suffers no amalgamation.

Above the glass cover to which the fork is fixed there is a cast-iron lid, which covers the entrance of the cable and shuts off the whole from all air and damp.

This new railway contact apparatus is in many respects an advance on the former constructions. It is quite removed from external damage, in consequence of its position under the rails, where it is almost completely buried in the earth, and also on account of its solid construction. It also avoids an evil which easily arises with other contacts made by means of mercury, viz., that the quicksilver in course of time oxidises on the contact surface, and thus becomes covered with a badly conducting film, whence faulty contacts may arise; for with each passing train the little cup becomes full to overflowing, the quicksilver runs over the edge, and throws the lighter oxide into the vessel G, where it does no harm. Hence the mercury which rises out of the pipe *f f* and makes the contact is always clean and bright.

Since there are no movable parts there is no cost to keep the apparatus in working order.

ON THE POSSIBLE CONNECTION OF HALL'S PHENOMENON WITH THE ROTATION OF THE PLANE OF POLARISATION OF LIGHT.

BY MISS J. M. CHAMBERS, B.SC.

Suppose the current in the cross (Fig. 1), when there is no magnetic field to pass straight from A to B, so that no component passes along L R, and suppose a magnetic field to be made whose force lines come up from the paper towards the spectator (that is, the field produced by a current whose direction is represented by the curved arrow), then a small component of the current will pass towards R if the cross is of gold, &c., so long as the field lasts (*i.e.*, it is permanent, not merely a transitory current produced in accordance with Lenz's law). If the cross is of iron, &c., the current will pass towards L. In fact, there is a small rotation of the equi-potential lines, and, therefore, of the E.M.F., against the direction of rotation of the current producing the field if the substance is of the nature of gold, copper, or bismuth, and with the current, if it is magnetic, like iron, &c. This is precisely the same thing as what I suppose takes place in the molecules of a transparent substance when a rotation of the plane of polarisation of light occurs, except that the rotation is in the opposite direction (at least I so understand the descriptions of Hall's phenomenon, though there is some confusion). Perhaps the reversal of the direction of rotation might be accounted for by remembering that the internal force lines of the molecular circuits are of opposite sign to the external ones, and here we are not dealing with a molecular current.

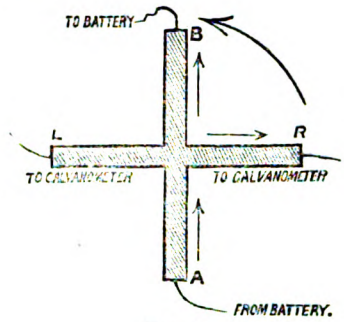

FIG. 1.

It may be noticed that, if we suppose the electrical vibration constituting light to take place outside instead of inside the molecules, the direction of rotation of the plane of polarisation is reversed, for the current A B is then (Fig. 2) attracted towards the left in its upward course and towards the right in its downward course.

But in the case of light we must suppose the ether which surrounds the molecules a more or less perfect insulator (since transparent substances are insulators), and then the vibrations will more likely take place inside than outside the molecules which we suppose infinitely conducting, or at least the motion of the electricity will be greater inside than outside. And we may suppose, if we please, that a vibration travels through several molecules, since molecules are probably very small in comparison with a vibration of light as they are in comparison with its wave-length. We may easily suppose that a vibration passes inside through the molecules, even if no electricity can pass in or out of them so that a *current* must pass outside them.

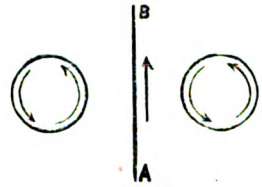

FIG. 2.

Viewed in this way Hall's phenomenon may be regarded as an action of the field on the current itself, when it fails to be able to move the conductor bearing it. Thus, as a north pole would be driven towards L (Fig. 1) by the current, the current is driven towards R by the north pole which gives the lines of the field.

Notwithstanding all this, however, the writer thinks that in the opinion of the majority of physicists, Hall's phenomenon cannot be thus explained; for the action thus explained should take place in all conductors whether thick or thin, while it is only in the very thinnest films of metal that any such effect has ever been observed. The phenomenon observed is probably a Peltier effect due to the strain on the conductor caused by the passage of the current in the strong magnetic field. (See papers by S. Bidwell, &c., *Phil. Mag.*, *Proc.* of the Royal Society, &c., 1884).

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending May 31st were £3,450.

SALE OF ELECTRICAL PLANT.—On Wednesday and Thursday, the 23rd and 24th inst., Messrs. Wheatley Kirk, Price and Goulty will sell by auction the surplus electrical plant, apparatus, and fittings of the Edison and Swan United Electric Light Company. Particulars will be found in our advertisement columns.

MILITARY TELEGRAPHY.

"So important will be the part played by military telegraphy for Outpost and Vidette duty, that the army which has the most efficient system of electric signalling will hold a trump card which may exert a decisive influence on the game in any future European war." These words, spoken by a military authority of high standing at the last meeting of the Telegraph-Engineers, were intended partly as a compliment to CAPTAIN CARDEW, the ingenious inventor of the system then under discussion, but partly also as a justification for bringing the subject under public notice. We join in the compliment, but it would have been deserved all the same without the publicity; and in the quarter most concerned with the matter, appreciation will, or ought to be, none the more hearty for being endorsed at a public scientific meeting. CAPTAIN CARDEW stated that his apparatus and methods had been kept a secret for four or five years; but that, as something very like them were being evolved independently elsewhere and for a different purpose, he had sought and readily obtained permission to explain the whole business. Too readily we think; for if it is really a fact that these English military telegraph appliances were a secret, they might have remained so with advantage, notwithstanding that the principle on which they were worked was being applied in other directions. We cannot suppose that the WAR OFFICE is afflicted with the common human weakness of claiming priority of invention merely for the sake of getting credit for it. The true explanation probably is that the Department has acted on its traditional policy, which, according to prevalent rumour, lets everybody into its secrets except those who have the best right to know them. Within the last few days a complaint has been made that while the staff officers of the British Army are forbidden to obtain maps of our Indian frontier, Russian emissaries are granted free access to all existing maps as well as to the localities themselves. If representatives of every European country have not already taken full stock of CAPTAIN CARDEW'S secrets, it will apparently be no fault of the WAR OFFICE.

We give a brief account of the system elsewhere, the essential features of which, however, we do not propose to enlarge upon, or to criticise. If they are as valuable as we are told they are, our sincerest hope must be that every foreigner who inspects them will treat them with contempt. On one or two collateral points, however, connected with the subject of military telegraphy, we would offer a few observations. First of all it seems necessary to define what we mean by military telegraphy. For those duties referred to by MAJOR BERESFORD, whose words we quoted at the beginning of this article, a telegraph of any kind is strictly military. It must possess mobility as a very first essential; it must be light yet capable of rough usage; the working apparatus should be simple and permanent; and the whole should be capable of working under the most disadvantageous electrical conditions. CAPTAIN CARDEW'S arrangement seems to answer the two last named requirements extremely well; and we believe that the equipment of our Field Telegraphs has answered the first requirement in the severe tests to which it has been put in the African campaigns North and South. Probably no nation is better provided in these respects, certainly none with better signallers. But the greater part of the work hitherto done by this military arm has been of a non-military kind; and it was evident the other evening that neither CAPTAIN CARDEW nor his critics were particular in drawing distinction between what is needed for the working of a telegraph line in the public service and what for a flying column, or for scouts with a line intended solely for keeping telegraphic touch with the main body. The two things are not the same, and on occasions may be totally different. Conditions essential for the one may be disregarded in the other; and to aim at perfection for both would be fatal to one, and that the most vital of the two. It is no objection to the Theiler Sounder or Telephone that they are not good for the "Traffic" which trails in the rear of an advancing Army. What is needed for that kind of telegraphy is something a great deal too perfect, too delicate and too sensitive for a strictly military telegraph, which is always in front of the Army, and for which ruder and more temporary appliances are preferable.

If these two very dissimilar requirements are not confused, there is no great difficulty in satisfying the one that is purely military. Different countries have different preferences. Germany appears, for example, to prefer the recording Morse. If Germany is ever to be England's foe in the field, which God forbid, we hope that the preference may continue. It is said that the military authorities of that warlike nation have scouted the idea of adopting any instrument which is non-recording. We do not want to combat the prejudice; but as it seems to be shared to some extent in this country, we would venture to ask what is the peculiar value of any recording instrument that does not actually write the despatch which is delivered? We know of none that does. Printed tape, we may safely conjecture, is nowhere delivered to the commanding officer; and as regards the operator, the process of reading is every bit as safe from a sounder instrument as from a so-called "printer." Flag-signals make no record; the heliograph leaves no sign except in the memory of the reader. Yet both these methods of signalling in military operations are now of recognised, and in some cases of exclusive utility. During the Franco-Prussian war illustrated periodicals gave us pictures of the German Army Telegraph offices, with telegraphists comfortably seated at fitted tables, and all the paraphernalia

Digitized by Google

nalia of paper-wheels, ink-writers and the rest; but nobody—nobody, at all events, but a German—would be so pedantic as to insist upon this cumbrous array of frail and troublesome gear forming part of every reconnoitering party's equipment. The apparatus is unsuited for transport; much delay must occur before it can be got ready for use, and the chances are that it will not work when it is wanted. None of these defects can be ascribed to the handy, effective, and trustworthy arrangement which CAPTAIN CARDEW has put the English War Authorities in possession of. We hope they will stick to it—with this reserve only, that if they secure any further improvement, or anything better to supersede it, they will keep the secret to themselves.

CORRESPONDENCE.

ANSWERS TO CORRESPONDENTS.

ELECTRIC BELLS.

If Mr. C. B. Callow will send samples and diagrams to *The Electrician* office, no doubt the editor will permit them being illustrated and published in a future number. At the same time, these articles are intended to assist amateurs in their work, and cannot describe every modification of any one article.

THE WRITER OF THE ARTICLES.

London, May 31st, 1886.

THE SOLDERING OF WIRES.

In reply to "An Amateur," the reason why spirits should not be used is because of the corrosion that takes place, which is quite sufficient to eat small wires quite asunder. The action is much hastened in damp situations.

THE WRITER OF THE ARTICLES.

London, May 31st, 1886.

KEEPING E CONSTANT AT A DISTANT POINT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could any of your readers tell me what great advantages the "multiple main" system, used at Paddington, has *for the above purpose*, over a single main of the same sectional area, with adjustable resistances at one point in the circuit, except the rather dubious one of costing a good deal more?—Yours, &c., D.

London, June 1, 1886.

DIVIDED MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the very interesting account you publish of the Paddington installation the writer introduces (p. 53) the Gordon divided main apparatus as being "considered the most important part of the system, for by its use the quantity of copper required in the feeding mains is reduced to one tenth of that used in the ordinary method." Nothing is said of the waste of energy consequent on this very economical reduction; my object in writing is, however, not to cavil at the dimensions of the mains as a whole, but at their divided state. Each component of a feeding main is practically a separate lead, and must be insulated from its neighbours, which insulation costs something. Why not use one solid main of the same area as the sum of the bundle of wires and introduce a variable resistance at the central station? There is the same loss from heating, but that loss is confined to one small space, and the inexhaustible ingenuity of the installation electricians would easily find means for utilising the heat given out in the rheostat. For example, it might be used to heat the feed water, or even cook a chop. It is true that this plan would relegate to the scrap heap all that indescribable conglomeration (Supplement, Fig. 1) of water-motor, governor, voltmeter and brake-block; but then the functions of this mysterious apparatus are already at a discount, for we read (page 53):—"Suppose a certain number of lamps are switched off, the pilot brightens a little, and calls the attention of *the attendant* to the voltmeter. He then moves the contact wheel, &c., and brings back the pressure to its normal value." Why that *attendant?* Is not the apparatus automatic?

There must be many of your readers beside myself who would like to see the complete theory of "divided mains," including such details as interest and depreciation on, and average power wasted in heating the mains, and the cost of a joule at Paddington.—Yours, &c., SYDNEY EVERSHED.

Kenley, Surrey, June 2, 1886.

RESEARCHES UPON THE SELF-INDUCTION OF AN ELECTRIC CURRENT.*

BY PROF. D. E. HUGHES, F.R.S.

Numerous researches have been made upon the self-induction of coils of wire, and but few in relation to the influence exerted by the nature and geometrical sectional form of the electrical conductor when employed in straight wires as in those of a telegraph line with the earth as a return, or those of a single wide loop where the distance of the return wire is sufficient to prevent any appreciable effect from the *mutual induction* of separate portions of the wire upon each other; our present theories class all non-magnetic metals together, taking only into account their specific resistance and the diameter of the wires; they admit, however, a certain modification in magnetic metals due to their magnetic permeability; but we have had but little experimental evidence of the effect produced.

The whole subject seemed to me worthy of experimental investigation, and I have lately† given the results of a first series of experiments made last year. I have remarked since writing that paper many new and important effects, and I have made a new series of researches, the results of which I wish particularly to point out in this paper. In my late researches I made use of a modified "Wheatstone bridge," together with a portion of my "induction balance," by means of which the induced or extra currents from the wire under observation were balanced by a secondary current induced from an independent circuit; this gave excellent results, but the method has been criticised as having the fault of not being clear in its indications. In order to meet this objection and also verify the results which I had previously obtained, I constructed an entirely new bridge, founded upon a most simple and well-known principle, and as the bridge admits of no change in the relative resistance of its sides its action can be easily understood; it is with this instrument that I have made my new series of experiments. The instrument consists of an ordinary Wheatstone bridge, with the exception that a telephone replaces the galvanometer; there are in addition two coils of insulated copper wire, one in each portion of two sides of the bridge, by means of which the mutual self-induction of its convolutions can be increased or decreased as desired. The electrical contacts are made either by a continuous periodic or turning fork contact maker, or by a peculiar clockwork rheotome which I have made, in which a contact spring rests lightly on a wheel whose roughened surface is divided into eight equal parts of contact and insulation, by means of which we receive on the telephone eight equal periods of sound and silence each revolution of the wheel. We are by this means better enabled to appreciate feeble sounds than if they were continuous, and as the wheel can be made to revolve at any between two and ten revolutions per second, we have from sixteen to eighty periods of silence between each rubbing contact per second.

Fig. 1 shows the theoretical plan of the electrical communications of the bridge.

A, B, C, D are the four sides of the bridge, the telephone J replacing the ordinary galvanometer; the sides C B and C D are formed of German silver wire, each 50 cm. in length, 0·5 mm. in diameter, and 0·85 ohm resistance; the sides A B and A D have also 0·85 ohm resistance, so that the four sides have equal resistance, and this remains a constant during the whole series of experiments. A E and A F is a continuous spiral of copper wire, formed of hard copper silk-covered wire of 1 mm. diameter and 4·80 metres in length, wound loosely on a boxwood cylinder of 3·50 cm. diameter and 30 cm. in length, on which it moves freely; the entire helix has 40 turns of 4 cm. diameter, each spiral being separated 5 cm. from each other; the spiral, however, is separated into two equal portions by giving a greater separation at the centre in order to allow it to be attached to a sliding collar of wood, by means of which we can press the spiral closer together on either side as

Digitized by Google

desired ; at E and F there are also adjustable collars of wood, and as the boxwood cylinder is graduated, we may (if the central collar is fixed) approach more or less either side of the helix, and read the degree of approximation of the coil, thus adjusting the mutual induction of each side to a perfect balance or zero. In practice I prefer moving the central collar, using the end collars only for the perfect adjustment of its zero, as we then have a double effect, viz., closing the coil, say, from A to F, increasing its mutual self-induction, and at the same time decreasing the previously balanced induction of the coil A E. This not only gives a wider range of effect, but renders the scale readings more uniform ; the end F of the helix is joined to about 10 cm. of German silver wire, completing the circuit from G to D. This supplementary German silver wire is simply for the purpose of making the resistance of AD equal to DC, and its length should be adjusted to this purpose ; the end of the helix E joins directly with the terminal N ; the wire to be tested X is joined to N and H ; from H to I there is a second supplementary German silver wire allowing us by means of the contact side M, which is in direct communication with B, to introduce more or less of the German silver wire in the side AB. The resistance of the wire to be tested should always be less than that of the opposite side of the bridge, and we then make up the total resistance of AB by sliding the contact slide M until the resistance of AB equals AD.

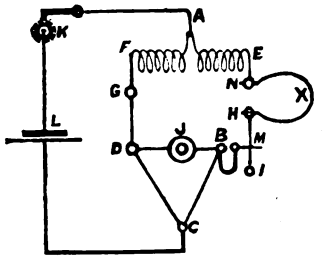

FIG. 1

It will be evident that in the whole series of experiments there can be no change in the resistance of either side whenever zero is found, the induction coils or balance having the same proportional current in all the changes of the wires under observation; the battery and telephone circuit present also a continuous absolute relation. We may, however, when desirable, keep the resistance from H to M a constant, and vary the resistance or the length of the German silver wire G D ; we then balance the wire X by an equal resistance on the opposite side of the bridge. But then the battery and telephone circuits no longer possess the invariable relations which are so extremely necessary in experiments of the nature of which I have been making. The battery circuit is joined in the usual manner to A C, the current can be interrupted by the rheotome K, or by means of a commutator (not shown in the diagram) close the battery circuit, and transfer the contact maker to the telephone circuit B D ; this allows us to observe the effect of an intermittent current compared with that of a constant or steady flow. M. Gaugain has termed the period of a steady flow of current the *stable period*, and that in which a rise or fall of the current takes place the *variable period* ; these terms have since been generally adopted by telegraph electricians, and in order to avoid introducing new terms they will be used in this paper.

It would require too much stace to enter into the details of the construction of the bridge ; special care is required in the construction of the balancing induction coils, and in securing perfect electrical contacts in all parts of the bridge. The induction balance requires calibration, and for this purpose I introduce as the wire X successive lengths of 10 cm. 1 mm. diameter copper wire, thus forming a table of values throughout the range of the induction balance, or by equal increments of 10 cm. of copper wire up to 20 metres. Having no unit of self-induction to which my results could be quickly and practically referred, I have adopted as unit the self-induction of a straight copper wire 1 mm. diam. and 1 metre in length ; this gives on my calibrated induction scale 100 degrees, and it is to this standard that all the comparative force of extra currents mentioned in this paper is compared. The self-induction of a wire is proportional to its length, consequently a source of error might exist in the different lengths of the supplementary resistance wire H I introduced to balance the resistance of G D ; but as we are enabled by the high specific resistance of German silver wire to obtain a very great change in resistance by a comparately small movement of the sliding scale, this error in most cases of comparative experiments is but a fraction of 1 per cent., and when taken into account, as it should be, the error no longer exists. The telephone used should be of the most perfect kind, and adjusted expressly for rapid and feeble sounds. I have found it best to employ an extremely soft Swedish iron diaphragm, without varnish or anything that can diminish or deaden the sound ; its fundamental note should be higher than those generally in use, or at least 500 double vibrations per second, for we have to deal with extremely rapid effects which on short wires cannot be rendered evident upon a galvanometer, but which with a telephone in perfect adjustment are heard most distinctly with an electromotive force in the battery circuit ranging from 0·001 to 0·250 ampere.

In the sketch of the communications the wire to be tested, X, is shown in the form of a wide loop, but in practice the instrument is constructed on two separate frames of wood articulated together at D, by means of which we can separate the terminals N H, and introduce straight wires, sheets, or tubes of lengths varying from 5 cm. to 1 metre. The object of my researches being to observe the self-induction which takes place in straight wires, or in those of a single wide loop where the reaction from any return wire is at such a distance that its influence is not appreciable, I shall, therefore, use the term self-induction to indicate the effects due to the electric current in its own portion of the wire, and mutual induction to those where the reactions of different portions of the current and circuit react on each other, as in the case of coils ; and although some theoreticians consider the two cases as the same, they are, as my experiments prove entirely distinct, for we have, as will be shown, for copper wires a low coefficient of self-induction with a high mutual induction, whilst in iron wires the reverse is the case, for we there have a high coefficient of self-induction with an extremely feeble coefficient of mutual induction.

Influence of the Nature of the Conductor upon its Self-induction.

I found, as shown in my late paper, that there was a marked difference in the specific inductive capacity of iron and copper, and this entirely agrees with well-known theories ; but I suspected that there might be some difference in the non-magnetic metals independent of their specific resistance. For this purpose I made a series of experiments with wires of the same length and diameter, but of different resistance. These showed a marked difference provided the current was increased in proportion to its diameter or conductivity, but no difference could be found when the current was kept a constant, and the interior differences in resistance of the wires were compensated by an external added resistance ; but if we take wires of different metals—all of the same length and resistance, but of different diameters—there is a marked difference due to the mutual reactions of the current in its own wire, being less in wire of large diameter than in small wires. These effects have been fully explained in my late paper, and have since been completely verified by the method used at present. I showed by the use of my late method a critical point in the rise and fall of the induced currents. This is not shown by the present method of compensating by external resistance, but the rapid decrease in the electromotive force of the induced currents, as indicated by the induction balance, is well shown by the present method. The following table shows the observed force of the extra currents for wires of the same length (1 metre), but of different diameters :—

—	mm. 0·25	mm. 0·50	mm. 1·00	mm. 2·00	mm. 3·00	mm. 4·00	mm. 5·00	mm. 6·00	mm. 7·00	mm. 8·00	mm. 9·00	mm. 10·00
Iron	760	621	530	360	269	220	190	171	152	138	128	124
Copper ...	129	113	100	89	82	78	75	73	72	71·5	71·2	71

The fall in force is now even more rapid than shown by my late method, and it will be seen that iron is peculiarly sensitive to an increase in diameter, having nearly six times the force of copper in wires of 0·25 mm., and not twice the force of copper in wires of 10 mm. section.

Reactions of an Electric Current in its own Portion of Conductor.

The phenomenon of a constant decrease in the electromotive force of self-induction, as measured by the induction balance, with each increase of the sectional area of the conductor, is well shown by the present method, and an experimental investigation of its cause has shown that we should not consider a current in a wire as a single element reacting solely upon exterior wires, but that the current acts precisely similar as would an infinite number of independent streamlets of current reacting upon each other in the interior of its own wire similar to their known effects upon exterior wires. My experiments demonstrate this to a degree that leaves no doubt on my mind as to its truth, for according to this view we should be able to reduce the self-induction to a very great extent by employing thin flat sheets where the outlying portions are at a comparatively great distance from the central portions. This I have experimentally proved to be the fact, but this experiment alone does not show if the reduction of self-induction is due to a different arrangement of the current in sheets as compared with solids. If the reduction is due to the greater separation of the streamlets, then we should be able to reduce this induction in a still greater degree by employing a conductor composed of numerous small copper wires through which the current is equally

Digitized by Google

divided, and which could be separated or brought close together as desired. This proves to be also an experimental fact, for the conductor formed of numerous strands has far less self-induction than a thin sheet when its wires are separated, so that they can no longer react on each other, and surpasses the thin sheet and approaches the value of a circular wire when these wires are brought near together, so that their mutual reactions can approximate those of the numerous streamlets in a solid conductor.

Iron shows a still greater reduction in its self-induction when in the form of thin flat sheets or numerous small iron wires separated from each other, with the exception that we cannot restore or approach the value of a solid wire by bringing them in close proximity. The reduction of the induced currents by employing thin sheets instead of a wire is so great in iron that we could not account for it on the mere separation of contiguous portions of the same current, but if we assume that the comparatively high force in iron wires is due to the induced circular magnetism, and that this almost disappears in flat sheets, we account for the fact that a thin flat sheet of iron has less inductive capacity than a similar sheet of copper of the same resistance, but of different widths; and if thin strips of copper, brass, lead, and German silver are compared with similar iron strips, and their resistance rendered equal by the added resistance in the bridge, no difference is found between iron and the non-magnetic metals, for under these conditions their inductive capacities appear equal.

(To be continued.)

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the concluding meeting of the summer session of this society, held at Great George-street, Westminster, on 27th May, Prof. Hughes, F.R.S., president, in the chair, Captain P. CARDEW, R.E., read a paper "On the Telephone as a Receiving Instrument in Military Telegraphy." After some preliminary observations Captain Cardew said:

The system I am about to describe, which was invented by me five years ago, has been kept secret by us hitherto, but as something very like it has been applied to communication with moving trains, and as it is certainly well understood by the principal makers of apparatus, I have without difficulty obtained permission to describe it and the experiments made with it. This will perhaps be best done by detailing the steps by which it was reached. Shortly after we became possessed, at Chatham, of any really well-made telephones, the idea of using them as receiving instruments for telegraph messages sent by the ordinary Morse code struck Major Armstrong, who was then in charge of the Electrical School, as probably applicable to field telegraphy, where interference from induction from parallel wires was not to be apprehended, and where the extreme sensitiveness of the instrument would probably enable work to be carried on in spite of faults of insulation, hasty joints, bad earth connections, &c. This idea was worked at for some time. It was found that there was some difficulty in reading, due to the almost perfect similarity of the make and break clicks in the telephone and the consequent liability to read the signals reversed. Still, this was probably to be overcome by practice, and eventually it was determined to try through what length of bare wire laid on the ground without any insulation the method would admit of carrying on work. Some experiments had also been carried out at this time with some vibrating sounders sent for trial by Messrs. Theiler.

These consisted of simple electro-magnets, the armatures being attached to a piece of German silver spring, fixed at both ends, and with a contact screw arranged so that when the armature was attracted it broke the current through the coils; in fact, just on the same principle as an ordinary chattering bell, but arranged to give a musical note. They were intended to be used as ordinary sounders, but the difficulty was, that they interfered with each other if more than two were used on one circuit.

The following is an extract from a report I made to the Royal Engineer Committee on the experiments carried out with this bare wire:—

Report on an equipment with 15 miles of bare wire laid on the ground, with a view to ascertain the possibility of signalling through it by means of telephones.

Telegraph School,
School of Military Engineering, April, 1881.

The wire consisted of 10 miles of No. 16 B.W.G. soft iron galvanised wire, and 5 miles of No. 16 B.W.G. copper wire. This arrangement possessed the disadvantage of keeping a continuous current on the line from the earth contact of the two wires, and of tending to destroy the iron wire, but, as the line was only required for a short time, this was not material.

Permission was obtained from the authorities of the London, Chatham, and Dover Railway, to lay the wire at the side of their line of rails. It was consequently laid in a loop extending from a short distance on the up side of the New Brompton Station to within a short distance of Newington Station, and back again on the other side of the line.

To ensure the wire being well out of the way of the traffic, it was laid in the *hedges* in many places. In other places it was laid on the ground, even picketed down under stiles so as to prevent its tripping people up. The ground was generally newly made or garden ground, and the soil of fair conductivity. Rather more than half the wire was thus laid in the hedges. At road crossings the wire was stretched over a pole at each side. For convenience, one end of the wire was brought into the Royal Engineers' Institute. This necessitated using poles to avoid interference with traffic, and for convenience some poles carrying existing lines were made use of. This introduced induction signals, so that, in getting signals through, the following difficulties had to be contended with, viz.: 1. Very bad insulation. 2. Continuous current from the different metals in the line wires and earths employed. 3. Induction currents confusing signals. The line resistance was never accurately obtained, this being impossible under the conditions, but it must have been about 900 ohms, while the insulation test from the institute gave on several days a resistance as low as 300 ohms, which of course included part of the line resistance, the position of the resultant fault being at any rate some distance beyond the end of the insulated wire, so that the true insulation resistance must have been extremely low. The first intention was to use the telephones as Morse instruments, with an ordinary key as before proposed, the connection being the same as for a sounder or Morse.

This was tried with batteries of 10 Leclanché cells at each end. At the institute, in a quiet room, there was no difficulty in reading these signals, but the ear had to be kept quite close to the instrument. At the other end there was some difficulty in reading signals when first tried, owing to a very high wind producing noises in the telephone. To get over this I tried the effect of putting on a Theiler sounder, sending a vibratory current out to line."

This was completely successful, the note produced being very easily read, and quite distinct from the induction signals, and the noises due to earth currents.

Signalling was carried on for several days by this method without any difficulty, clearly demonstrating that by this means signalling can be kept up through bare wire laid on the ground (as rapidly as cable), and afterwards poled and insulated when circumstances permit.

Another advantage of this use of the telephone is, that no adjustment of the receiving instrument is ever necessary, thus eliminating a fruitful source of delay.

For ordinary insulated lines the battery power required is very small, and the telephones are ready when necessary to be used in the ordinary way, and would no doubt be found very useful by the General and his staff as a means of personally communicating orders.

Another and preferable method of connecting the Theiler Sounder is so arranged that:—1. The current through the Theiler sounder is practically uninfluenced by any change occurring in the line resistance. 2. In the case of a dirty back contact in the key (a fault of frequent occurrence causing much delay), continuity will still be established through the coils of the Theiler Sounder. 3 Fewer cells can be employed (four cells Leclanché being quite sufficient for ordinary circuits).

The note given by the Theiler sounder in the telephone is quite as loud as the tone of the ordinary sounder under ordinary circumstances. When working through bare wire laid on the ground it is of course low, but still quite distinct if held close to the ear.

A simple apparatus for holding the telephone in the required position, so as to leave the arms free, could be easily designed. Two telephones, one to each ear, might then be advantageously employed.

From the results of this experiment with bare wire, I feel confident in recommending the employment of this combination of Theiler sounder and telephone in place of the ordinary sounder for field service, over which it possesses the following advantages:—

1. The possibility, as demonstrated, of working through a considerable length of bare wire.
2. The receiving instrument requiring no adjustment for altered conditions of line and different stations, &c.
3. The reduction of the battery power required to be carried to at most one-fourth of the present requirements.
4. The continuity of the line being ensured, independently of the back contact of the key.
5. The power of working through very bad earths, saving much time in very dry places.
6. That the note signals are more easily read than the interval signals by men untrained to either.

Experiments were immediately afterwards carried out by the field telegraph troop at Aldershot with this system, which was reported on very favourably by Colonel (then Major) Hamilton, R.E, commanding the troop, from whose report I need only extract the following paragraph:—

"I should add to the above, that the experiment was tried of poling the line which had been laid on the ground while messages were being sent through the line, and the poling did not in the least interfere with the reading of the messages. It therefore follows that a line of bare wire may be laid as fast as an army advances, and that a party may follow slowly and pole the line; the communication being established from the first laying out of the line."

An extensive trial of the system was in consequence approved. Rather unfortunately, in order to save expense, it was proposed to convert the existing old pattern field sounders into Theiler or vibrating sounders.

Some of these converted instruments and telephones were taken out to the first Egyptian Expedition in 1882; and this system was used exclusively in sending the messages from the field of Tel-el-Kebir from 8:30 a.m. to 6 p.m.

A new pattern of vibrator was, however, then considered essential, and this was the pattern designed. [Shown.] As the noise made by the vibrator and the telephone at the sending end was sometimes a nuisance, it was reduced to a minimum in this instrument by using a very light armature—simply a piece of ferrotype or tinned iron—and by means of a small key at the side of the signalling key which, when depressed by one finger, short-circuited the telephone.

It was considered desirable to practically determine, if possible, the limit of distance to which the system was workable on a long aerial line isolated from other wires. As this could not be obtained in England the

Digitized by Google

Indian Government was asked to try the experiment, and the following is an extract from the report of the Electrician of the Government Telegraph Department:—

"Weather clear and fine.

"Worked Tuticorin, a distance of 375 miles, by wire from Calicut, with 30 Minotto cells, reducing battery subsequently to four cells. Signals from Tuticorin very clear, and could, with the stronger current, be read on telephone held at some distance from the ear; but with the weaker current it was necessary to hold the telephone pressed against the ear.

"The thick, or No. 1, armature, was used at both ends throughout.

"The two parallel wires to Beypore (9 miles), and Malapuram (18 miles), also line to Vayitri and Tellicherry, were working at the same time, and all together during the above experiments, the two latter being suspended on same posts as the others, for a distance of ten yards from the office only.

"The beats from the offices working as usual were distinctly audible in the telephone, but, except when the weaker battery of four cells was on, the signals from Tuticorin on the vibrator were not interfered with—the musical note riding above the induction beats."

This clearly shows that, with an isolated aërial line, very great distances could be worked by this system without translation.

In 1883 some experiments on General Post Office wires were made with this system, of which the following is a condensed report:—

"1*st Experiment.*—New Cross to Chatham (30 miles), worked easily with one cell, and very good signals with six cells; also worked through wet string and human bodies.

"2*nd Experiment.*—New Cross to Bristol, 123 miles on poles and eight underground. Chatham to Bristol. 158 on poles and 10 underground—wires on the same poles—could hardly be got through with 60 cells.

"Ordinary apparatus worked with 30 cells.

"The vibration currents were destroyed by induction, especially in the underground part through London.

"4*th Experiment.*—Two parallel wires between New Cross and Chatham, fitted with ordinary ink-writers, also between the two vibrators and condensers, as in diagram."

This was an idea of mine to get an independent vibration-circuit superposed on ordinary working, and was quite successful, all three circuits working quite independently. Signals audible with 2 and good with 10 cells on vibrators, 30 on the Morse.

In place of the condensers an ordinary plate lightning protector was fitted, and afterwards a resistance of 10,000 ohms, without interrupting the working.

In commenting on these and subsequent experiments on 1st October, 1883, I remarked: "It is worth consideration, whether the system of working tried successfully in Experiment 4 could not be usefully adopted in the postal telegraphs. . . . The method is much improved by the addition of magnets on the Morse circuit, as the Morse clicks can be practically softened off in the telephone to such an extent, by being passed through the coils of a magnet, as to avoid all interference with the vibration signals."

Immediately after this I tried the effect of working with the addition of an electro-magnetic coil of considerable inductive power, on each end of the line, between the Morse instruments and the vibrators, and found it work perfectly.

This method was soon afterwards tried between New Cross and Chatham, and worked perfectly, although the condition of the line was so bad and variable that we could not succeed in duplexing the Morse. By this method, therefore, two independent circuits can be at once established on a single wire with single instruments, without any balancing or nice adjustments.

In order to simplify the connections for field purposes, I obtained some ½ M.F. condensers and magnet coils and fixed them inside a small box with three terminals outside, marked M. L. & V.—the coil being attached to M. & L., and the condenser to L. & V.

The boxes were then filled up solid with white paraffin, and the ends secured. They were, I think, about 9in. by 4 by 3, or perhaps less. The iron cores of the magnets were joined at both ends to form a complete magnetic circuit. To these boxes I gave the name of "Separators."

The instructions were simple:—"Join the Morse to M, the line to L, and the vibrator to V, and fire away." Of course it it evident that this separator system is practically the same as Van Rysselberghe's, but it was brought out quite independently, and in the manner detailed; and the fact that he can successfully employ it with the weak speaking currents shows how certainly it must work with the far more powerful vibration currents.

Quite recently an account has appeared in the papers of a somewhat similar system brought out by Mr. Edison, and marked with his usual ingenuity. No doubt it will be taken up now that the prophet belongs to another country.

Although the separators were not tried either in Bechuanaland or Egypt, the vibration system was found very useful, notably in one case in Egypt, where working was carried on for six weeks through a bare wire laid on the ground for a distance of 23½ miles, from Kaibar to Abu Fatmeh, and absolutely buried for a distance of 200 yards through the camp at Kaibar. This distance is rather longer than that worked through in England, viz., from Chatham to Faversham; but it was not really so severe a case, as the ground in the Soudan was decidedly dry, and that in England distinctly wet. The most noteworthy feature of this trial is that only two small Leclanché cells were used at either end, and that with this small battery power, through a line making dead earth all the way, the call signal was audible, even without holding the telephone to the ear.

The vibration system is now applied by us in many ways. For instance, with ordinary telephones a buzzing armature is fixed to the induction coil, causing a vibratory current in the primary circuit, which is reproduced as a call signal in the telephone, thus dispensing with the ordinary bell. The note is loud enough to be heard in an adjoining one.

I have also adapted it to an instrument for testing lightning conductors. [Instrument explained.]

The last instrument I submit to-night is a "Combination Box," adapted for speaking or telegraphing:—

The vibrating transmitter is double wound and acts as an induction coil for the transmission of speech. The microphone transmitter used is a "Hunnings" or "Moseley," arranged with a handle which forms a switch. This solution of the switch difficulty, which gave us some trouble, is due to Quartermaster-Sergeant Kenney, R.E., and is certainly the most efficient we have yet tried. It performs two offices: when speaking, it is squeezed in the hand, and completes the circuit through the microphone and primary coil; when listening the pressure is relaxed, the battery circuit is broken, and the secondary coil short-circuited. Thus the battery circuit is never kept on longer than is absolutely necessary, a most important point in the field, where small patterns of cells must be used and renewals may not be at hand.

In the discussion which followed, Major Beresford said that in any future European war the army whose vidette and outpost service was equipped with efficient telegraphic appliance would possess a trump card of enormous value; and that the system described by Captain Cardew had the great advantage of working satisfactorily under the most seeming disadvantageous conditions, besides enlarging the capacity of the single wire by means of the "separator." Mr. Von Treuenfeld was anxious to have an authoritative opinion as to the admissibility of non-recording instruments in active service. The German military authorities would not listen to any proposal which involved the use of an instrument that made no record of the signals Mr. Donovan on this remarked that throughout the American civil war non-recording sounder instruments were employed. After some little further discussion, Captain Cardew briefly replied.

Captain R. H. Sankey, R.E., then read a paper on "A Problem Relating to the Economical Electrolytic Deposition of Copper."

At the beginning of last winter I was asked by Mr. W. Goolden (of the firm of Goolden and Trotter) to assist him in a scheme for depositing copper on a large scale, and in discussing the question the following problem presented itself:—

Let it be assumed that an installation for the electrolytic deposition of copper consists of a number of depositing tanks, each containing the same cathode area and supplied with current by one dynamo, whose activity is given. Find what number of tanks, what cathode area per tank, and what density of current per square foot of cathode should be adopted, and in what manner the tanks should be electrically connected in order that the copper may be deposited at a minimum cost.

This problem, although of considerable practical importance, does not appear to have been attempted, at any rate in a theoretical manner. It is a somewhat complicated problem, and the following does not pretend to be more than a preliminary and approximate solution, though probably sufficiently accurate for practical purposes.

In the first instance the tanks will be supposed to be arranged in simple series.

Let

n = number of tanks;

S = surface of cathode per tank, expressed in square feet;

γ = density of current per square foot of cathode;

r = tank resistance per square foot of cathode;

ε = counter electromotive force of each tank;

then

γS = current flowing through each tank;

$\frac{r}{S}$ = resistance of each tank (not including leads);

and therefore the energy absorbed by *one* tank is

$$\frac{r}{S}\gamma^2 S^2 + \varepsilon\gamma S,$$

and the energy absorbed by all the tanks is

$$n\left(\frac{r}{S}\gamma^2 S^2 + \varepsilon\gamma S\right).$$

The energy absorbed by the leads only remains now to be accounted for. Whatever the number and size of the tanks, this portion of the energy can, by arranging the leads, be made equal to any desired proportion of the total energy expended in the circuit. A suitable assumption would therefore appear to be to make the loss of energy in the leads constant, in which case it can be expressed by $\alpha C V$, α being a constant to be afterwards determined.

Hence, from the conditions of the problem

$$n(r\gamma^2 S + \varepsilon\gamma S) = (1-\alpha) C V \quad . \quad . \quad . \quad . \quad . \quad (1),$$

which is the equation of energy.

Now, the cost of depositing *one* lb. of copper is

$$= \frac{\text{daily cost of all the tanks} + \text{daily cost of activity} + \text{daily cost of superintendence, \&c.,}}{\text{weight of copper deposited per diem,}}$$

and it is required to find what values of n, γ, and S make this expression a minimum.

Digitized by Google

The first step is to find expressions for the various items of expenditure, and for the weight of copper deposited.

Daily Cost of all the Tanks.—This item will clearly be n times the daily cost of *one* tank, which it is found can be expressed by

$$k + k_1 S + k_2 S^2 + k_3 S^3$$

where k, k_1, k_2, and k_3 are constants as regards any particular installation. This expression will be denoted by $\phi(S)$.

The factors k, k_1, k_2, and k_3 depend on the design adopted for the tanks, on the amount of floor space provided, on the style of building, on the leads, on the maintenance expenses, &c. The following table gives in detail the various heads of expenditure, both as regards first cost, maintenance, and working expenses, and the above factors have been worked out for an average case. Although the *actual* values of these factors will vary, according to the circumstances of each installation, the *relative* values will not, it is thought, be materially altered.

Daily Cost of Activity.—The daily cost of activity, which will be expressed by A, depends on the size of the installation, on the class of boiler, engine, and dynamo used, on whether water power is available, on the number of hours worked per diem, &c. Under this head must also be included the cost of the apparatus required to keep the solution in motion. The daily cost of activity depends to a certain extent on the commercial efficiency of the dynamo; and in so far as this efficiency depends on the strength of the current, this item of expenditure will vary. But the variation, if any, is small, so that remembering that the watts are constant it can be assumed that the cost of activity is constant.

Daily Cost of Superintendence.—This item depends principally on the size of the installation, and can be regarded as constant for any particular installation; it will be expressed by B, and is taken to include all general expenses.

Weight of Copper Deposited.—It is known that one ampere will deposit $\frac{1}{384}$ lb. of copper per hour, so that the weight of copper deposited in each tank per hour is

$$\frac{\gamma S}{384}$$

and therefore, if work is carried on for T hours per diem, the total weight of copper deposited in the n tanks per diem will be

$$\frac{n \gamma S}{384} . T$$

Hence, finally, if U is the cost of depositing *one* lb. of copper

$$U = \frac{384}{T} \cdot \frac{n\phi(S) + A + B}{n \gamma S} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

This equation, combined with equation (1) and differentiated in the usual way to obtain a minimum value, gives, after some reduction,

$$S\left(\frac{r}{r + \frac{\epsilon}{\gamma}}(A+B) - n\phi(S)\right) D\gamma + n\gamma\left(S\,\phi^1(S) - \phi(S)\right) DS = o;$$

and equating the co-efficients of $D\gamma$ and DS to zero,

$$n = \frac{r}{r + \frac{\epsilon}{\gamma}} \cdot \frac{A + B}{\phi(S)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and

$$S = \frac{\phi(S)}{\phi^1(S)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

and the values of n, γ, and S, which satisfy equations (1), (3), and (4), are those which make U a minimum.

A complete solution would be too complicated for practical use, but an approximate solution can be obtained, as follows:—

For equation (3) the following average values can be assigned:

$$r = 0{\cdot}15 \text{ ohm},$$
$$\epsilon = 0{\cdot}02 \text{ volt},$$

and, as it unlikely that γ will be less than 3 amperes per square foot, so that in practice the smallest value of $\frac{r}{r + \frac{\epsilon}{\gamma}}$ is, under these conditions, 0·96.

Therefore, as a first approximation,

$$n_1 = \frac{A + B}{\phi(S)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5);$$

or,

$$n_1 = \frac{\text{daily cost of activity} + \text{daily cost of superintendence, \&c.,}}{\text{daily cost of one tank.}}$$

Returning to equation (4) and substituting for $\phi(S)$ and $\phi^1(S)$ their values, namely,

$$\phi(S) = k + k_1 S + k_2 S^2 + k_3 S^3$$

and

$$\phi^1(S) = k_1 + 2k_2 S + 3k_3 S^2,$$

it will be found that

$$k_2 S^2 + 2k_3 S^3 = k.$$

TABLE SHOWING COST OF DEPOSITING TANKS.

Items of Expenditure.	k	k_1	k_2	k_3	Cost when S=100.	Cost when S=1,000.

* Supposed to be made of wood. Size, when S = 100, 5′ 0″ × 2′ 6″ × 3′ 0″.

For instance, taking the values of k, k_2, and k_3 given in Table I., it will be found that

$$S = 160 \text{ sq. ft.}$$

It will be observed that the value of S, which makes U a minimum, is dependent only on the factors k, k_2, and k_3, and is independent of the factor k_1, and also of n, γ, and C V. It follows that the size of the tanks in which copper can be deposited at a minimum cost is independent of the size of the installation, and depends only on the design adopted for the tanks, and on the proportion of energy wasted in the leads.

Within certain limits, however, the value of S has but little influence on the value of U, as will now be shown.

In equation (1) the term $n \epsilon \gamma S$ is comparatively small, as will be seen on referring to the values previously given for r, ϵ, and γ, and therefore

$$n r \gamma^2 S = (1 - a) C V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Combining this equation with equations (2) and (5), and reducing, it will be found that, *approximately*,

$$U = \frac{768}{T}\left(\frac{(A+B)\,r}{(1-a)\,C\,V} \cdot \frac{\phi(S)}{S}\right)^{\frac{1}{2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

$$= \frac{768}{T}\left(\frac{(A+B)\,r}{(1-a)\,C\,V}\right)^{\frac{1}{2}} \cdot \left(\frac{k}{S} + k_1 + k_2 S + k_3 S^2\right)^{\frac{1}{2}}$$

Now, having regard to the values of k, k_1, k_2, and k_3, given in Table I., it will be seen that for small values of S, U is large, and at first, as S increases U diminishes, but that when S lies between certain limits the value of U alters very little—beyond the upper limit U increases gradually as S increases. This result is clearly shown by the curve in Fig. 1, and it will be seen that from S = 160 to S = 100, and from S = 160 to S = 250, the value of U only increases 1 per cent.

Further, if the values of k, k_2, k_3 were doubled, k_1 remaining constant, the corresponding limits for S would be 105 and 240 square feet; and if k, k_2, and k_3 were halved, the limits would be 65 and 360 square feet.

Making, therefore, every allowance for inaccuracies in the estimates, by means of which the values of the factors k, k_1, k_2, and k_3 were obtained, and for the effect of various designs and circumstances (and it is to be observed that these limits of S depend on the *relative* values of the factors and not on their absolute values), it would appear that any value of S lying between the limits of 100 and 250 square feet can be chosen without practically increasing the cost of depositing from the absolute minimum.

Digitized by Google
REESE LIBRARY OF THE UNIVERSITY

Having therefore selected some suitable values for S lying between the above limits, the daily cost of *one* tank (*i.e.* ϕ (S)) can be found, and to do this it is unnecessary to find k, k_1, k_2, k_3, but an ordinary estimate of the cost is all that is required. n_1 can then be obtained from equation (5) and then γ_1, with sufficient approximation, from equation (6). Substituting in equation (3) the value of n is obtained, and then a more accurate value for γ. It is assumed, of course, that A, B, r, and ϵ are known.

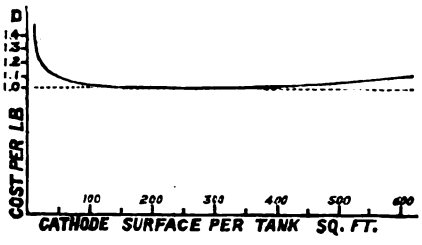

FIG. 1.

So far it has been assumed that the tanks are arranged in simple series; it remains to be seen whether anything is gained, or otherwise, by grouping a number of the tanks in parallel and placing these groups in series.

Electrically, each group can be looked upon as if it were *one* tank, having a cathode surface equal to the sum of the cathode areas of all the tanks in the group. Thus, if there be m tanks in each group, each tank having a cathode surface of S square feet, each group can be regarded as *one* tank having a cathode surface of m S square feet; and, if the additional leads required to connect the groups together are for the moment neglected, it is clear that the daily cost of the group will be $m\ \phi$ (S). Hence, applying equation (7)

$$U = \frac{768}{T}\left\{\frac{(A+B)r}{(1-a)CV}\cdot\frac{m\,\phi\,(S)}{m\,S}\right\}^{\frac{1}{2}}$$

r, with the proviso relative to the leads, the cost is the same as if the tanks were placed in series. But the additional leads required to connect the groups will cause additional expense by the energy wasted in them, and by the increased first cost.

On the whole, therefore, grouping the tanks is not so economical as placing them simply in series. Grouping the tanks entails also the disadvantages of requiring larger currents in the mains, and a greater difficulty in regulating the current per tank.

It remains to be found what proportion of the energy should be wasted in the leads and connections—in other words, what value should be given to the factor a. Following Sir W. Thomson's rule, the leads should be so proportioned that the cost of the energy expended is equal to the interest on first cost and the depreciation. The value of a depends, therefore, on the circumstances of each installation. For example, taking S = 100 and γ = 5 CV = 24,000 watts and A = 350 pence as an average case, it is found that

$$a_1 = \frac{1}{40}$$

and the sectional area of the leads would be about 2 square inches. The leads connecting the dynamo to the tanks were taken into account in finding the above value of a_1, but no allowance was made for switches and connections; adding about one fourth for this purpose

$$a = \frac{1}{30}.$$

The results arrived at are tabulated below, and it is hoped they may be of practical use.

1. The tanks should be arranged in simple series.

2. The cathode surface per tank for minimum cost of deposition is independent of CV, and can be selected between the limits of 100 and 250 square feet.

3. The number of tanks for minimum cost of deposition can be obtained from

1st approximation,

$$n_1 = \frac{\text{daily cost of activity} + \text{daily cost of superintendence, \&c.,}}{\text{daily cost of one tank.}}$$

2nd approximation,

$$n = \frac{r}{r + \frac{\epsilon}{\gamma}}\,n_1$$

4. The density of current can then be found approximately from

1st approximation,

$$\gamma_1 = \sqrt{\frac{(1-a)\,CV}{n_1\,r\,S}}.$$

2nd approximation

$$\gamma = \sqrt{\frac{(1-a)\,CV}{n\,r\,S} - \frac{\epsilon\,\gamma_1}{r}}.$$

5. The cost of depositing *one* lb. of copper can be found (approximately) from

$$U_{(\text{min.})} = \frac{768}{T}\left(\frac{(A+B)\,r}{(1-a)\,CV}\cdot\frac{\phi\,S}{S}\right)^{\frac{1}{2}}$$

6. The elements for winding the dynamo can then be found, since CV is given and $C = \gamma S$ is known.

The following numerical examples are appended as illustrations:—

Example No. 1.

Let CV = 24,000 watts, S = 100 sq. ft., ϕ (S) = 6·5 pence, A = 360 pence, B = 50 pence, r = 0·15 ohm., ϵ = 0·02 volt, $a = \frac{1}{36}$, working 10 hours a day;

then
$$n_1 = \frac{360+50}{6\cdot5} = 63$$

$$\gamma_1 = \sqrt{\frac{(1-\frac{1}{36})\,24{,}000}{63\times0\cdot15\times100}}$$

$$= 4\cdot95 \text{ amperes per square foot;}$$

hence
$$n = \frac{0\cdot15}{0\cdot15+\frac{0\cdot02}{4\cdot95}}\times63,$$

$$= 61 \text{ tanks,}$$

$$\gamma = \sqrt{\frac{(1-\frac{1}{36})\,24{,}000}{61\times0\cdot15\times100} - \frac{0\cdot02\times4\cdot95}{0\cdot15}}$$

$$= 4\ 97 \text{ amperes per square foot,}$$

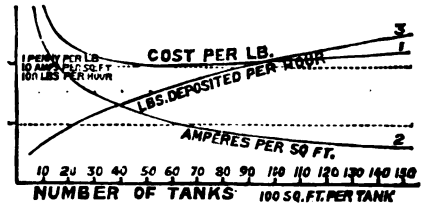
and
$$C = \gamma S = 497 \text{ amperes,} \qquad V = \frac{24{,}000}{497} = 48 \text{ volts.}$$

The cost of depositing *one* lb. of copper will be

$$U_{(\text{min.})} = \frac{768}{10}\left\{\frac{(360+50)\,0\cdot15}{(1-\frac{1}{36})\,24{,}000}\cdot\frac{6\cdot5}{100}\right\}^{\frac{1}{2}}$$

$$= 1\cdot01\text{d.}$$

The curve marked (1) in Fig. 2 has been drawn to show what effect altering the number of tanks has on the cost of depositing (S remaining constant, and using the data of this example). It will



COST PER LB.

FIG. 2.

be observed that the cost is a minimum when n = 61, and that it increases when n is either increased or diminished. Of course, C V is supposed to be constant, and consequently γ will very, increasing as n diminishes and *vice versâ*. Curve (2) shows the manner in which γ varies. Curve (3) shows the number of pounds of copper deposited per hour for the corresponding values of n. From this curve it appears that the number of pounds of copper deposited per horse-power is no criterion of the merits of an installation.

Example No. 2.

Let CV = 24,000 watts, S = 100 sq. feet, ϕ (S) = 6·5 pence, A = 200 pence (water-power), B = 50 pence, r = 0·15 ohm, ϵ = 0·02 volt, $a = \frac{1}{16}$, working 10 hours a day;

then
$$n_1 = \frac{200+50}{6\cdot5} = 38$$

$$\gamma_1 = \sqrt{\frac{(1-\frac{1}{16})\,24{,}000}{38\times0\cdot15\times100}}$$

$$= 6\cdot23 \text{ amperes per square foot;}$$

$$n = \frac{0\cdot15}{0\cdot15+\frac{0\cdot02}{6\cdot23}}\times38 = 37;$$

$$\gamma = 6\cdot28 \text{ amperes per sq. foot;}$$

$$C = \gamma S = 628 \text{ amperes,}$$

$$V = \frac{24{,}000}{628} = 38 \text{ volts,}$$

$$U_{(\text{min.})} = \frac{768}{10}\left\{\frac{(200+50)\,0\cdot15}{(1-\frac{1}{16})\,24{,}000}\cdot\frac{6\cdot5}{100}\right\}^{\frac{1}{2}}$$

$$= 0\cdot8\text{d.}$$

Example No. 3.

Let CV = 4,000 watts, S = 100 sq. feet, ϕ (S) = 6·5 pence, A = 70 pence, B = 40 pence, r = 0·15 ohm, ϵ = 0 02 volt, $a = \frac{1}{25}$, working 10 hours a day;

Digitized by Google

then

$$n_1 = \frac{70+40}{6\cdot5} = 17$$

$$\gamma_1 = \sqrt{\frac{(1-\frac{1}{25})\,4,000}{17\times0\cdot15\times100}}$$

$$= 3\cdot87 \text{ amperes per sq. foot,}$$

$$n = \frac{0\cdot15}{0\cdot15+\frac{0\cdot02}{3\cdot8}} = 16$$

and

$$\gamma = 3\cdot95 \text{ amperes per sq. foot,}$$

$$C = \gamma S = 390 \text{ amperes,}$$

$$V = \frac{4,000}{390} = 10\cdot1 \text{ volts,}$$

$$U_{(\text{min.})} = \frac{768}{10}\left\{\frac{(70+40)\ 0\cdot15}{(1-\frac{1}{25})\ 4,000}\cdot\frac{6\cdot5}{100}\right\}^{\frac{1}{2}}$$

$$= 1\cdot28\text{d.}$$

PROF. FORBES' CANTOR LECTURES.

LECTURE III.

(Continued from page 57.)

I will carry the analogy still further; but I will remind you of the remarks which I made in my lecture on what are called electric potentials. I said there was a difference of electric potential between any two bodies which were electrified, one positively and the other negatively, so also I say there is a difference of potential between the two ends of this magnet. I said that we meant by a difference of potential that work was done in carrying something from one point to another. There is a difference of potential between a floor and a table, because work is done in lifting a mass from the floor to the top of the table. There is also a difference in magnetic potentials between the two ends of a magnet, because work must be done in carrying a magnetic pole from the one to the other. The condition which determines a rearrangement of the magnetic state, owing to the existence of the magnetising force, is called magnetic induction, and the effect produced in any given case depends partly upon the direction in which the magnetic force is acting and partly upon the substance and shape of the body which is being acted upon. Iron offers less resistance than any other material to the induction due to the magnetising force. I have here a compass needle suspended, which will enable me to illustrate some of the phenomenon of induction by throwing the image on the screen. [Experiment.] The compass needle is now suspended in a certain direction. I wish to show the induction of magnetism in a piece of iron by subjecting it to a magnetising force. We know from what has already been said that the earth's magnetism acts in a north and south plane, and, moreover, that in these latitudes the vertical component is much greater than the horizontal. At present, therefore, the bar, being held in a nearly perpendicular position, is subject to the action of the magnetising force of the earth, which is trying to pull the north end downwards and trying to drive up the south magnetism at the other end. If this were a magnet freely suspended, as the dipping needle was, and if this were the north end, this bar would set itself in this direction [indicated]; but it has no magnetism of its own; its magnetic properties are entirely due to the inductive action of the earth. I will try and show you that this is the case. If that is the case, then the earth is creating a north pole at the lower end of the bar and a south pole at the upper end, and even if I reversed the iron bar we should still have a north pole at the lower and a south pole at the upper end. [Shown.] I will bring the upper end first towards the needle. You see the direction in which the needle tends to go—that is to say, it assumes a horizontal position, as shown on the screen. [Shown.] The opposite end of the iron will certainly be found to be magnetised in the opposite direction. Now, the remarkable thing I wish to show you is this—that when I twist the iron round, I shall reverse the polarity of the iron bar. I now present that end of the bar which deflected the needle vertically before, and it deflects it horizontally now [showing], and the other end deflects it in a vertical, instead of a horizontal, position.

I wish now to show you some effects which enable us to get a very fair notion of the ultimate nature of the magnet. I have mentioned that in the laboratory it is not very convenient customarily to use pieces of loadstone as magnets, but that we use magnets which have been artificially made. We can convert pieces of common steel into magnets in a variety of ways. One way is by making use of the loadstone itself and drawing one of the poles over the piece of steel. On drawing the losdstone over the piece of steel always in the same direction the steel is converted into a magnet. Here is a piece of steel tape. First, I will show you that it is not sensibly a magnet, that it does not seriously influence the compass needle. Now, I lay down this piece of steel tape and draw the poles of the magnet over it always in this direction. [Indicated.] By this means I am producing a magnetising force, and that is an action very much the same as was produced by the earth's magnetism on the soft iron. The only difference is that this steel is a material which, when it is magnetised, does not lose its magnetism easily. Therefore, it is not easily reversed, as you saw in the iron bar. I have now stroked this over several times with one of the poles of this magnet. On bringing it into the neighbourhood of the compass the needle is violently deflected [shown], thus showing that this steel tape has been converted into a magnet. One end attracts the needle into a horizontal position, and the other end reverses it. Now, the whole of this magnetism appears to reside in the two ends of the magnet, and it might be thought that upon breaking this steel you ought to have the whole of the north magnetism at one end, and the whole of the south magnetism at the other. I will try the experiment, and see what happens. [Shown.] I have broken the steel into two portions. I bring each end in turn towards the needle, and it is moved in opposite directions. It is the same with the other fragment. The two ends still have opposite polarities when I have broken the magnet in two, and I might go on breaking it again, and still there would be both north and south polarity in each of the fragments. I might, in fact, go on breaking it a great many times, but I should always have the two poles north and south. I will now demagnetise this piece of steel. This is done by heating it to a red heat in a Bunsen flame. The steel loses its magnetism when sufficiently heated. I will let it cool, and then bring it to the needle and test it, and nearly the whole of the magnetism will probably disappear. In the meantime I may say that from the fact that we cannot find the whole of the north magnetism at one end of the magnet and the whole of the south magnetism at the other, and that when we break it we always find both north and south magnetism in the same piece, it has been supposed by many that it does not matter how far you were to subdivide the iron; if you were to break it down to small pieces you would always have opposite magnetisms at the two ends of the iron—that is to say, carrying it to the extreme limit that the actual molecule of iron is magnetised and has magnetic polarity, one end of the molecule being north and the other end being south. This is a theory which is now pretty generally accepted. The steel tape is now cold; having brought it under the influence of heat, and allowed the molecules to vibrate about a little and arrange themselves in a new manner, they have no longer that linear arrangement which constitutes magnetism, so that we have destroyed the magnetism in this piece of steel, as you see when I bring it near the compass needle. [Shown.] The theory, as generally accepted nowadays, is that molecules are all magnetic intrinsically, and that in *every* piece of iron the molecules are of that nature, but that when we subject the iron to a magnetising force, then we arrange the direction of those molecules so as to be all parallel to one another, and in the same direction. It is perfectly clear that if we had a lot of little magnets all arranged in the same direction and parallel to each other—with all their north poles pointing in the same direction and their south poles pointing in the other direction—then the whole group of these magnets would act as one large magnet does. They would attract the compass needle in exactly the same way as we find a magnet attracting the compass needle. Moreover, we know that if a mass of iron were so constituted—made of molecules having intrinsic polarity—and that if it were subjected to a magnetising force, and if those molecules were free to move, they would arrange themselves in one direction; and thus the whole mass of iron would evince magnetic properties just as you saw the iron bar do when subjected to the inductive action of the earth's magnetism. This is the theory of magnetism which is most generally accepted. I have shown you one way of converting iron into a magnet. But we have another, and a much more potent manner of doing so, and that is by the aid of an electric current, and with the discovery of this power in an electric current to convert iron into a magnet the field was opened for an enormous number of practical appliances of electricity and magnetism. I will now show you electro-magnets of different shapes and the effects which can be drawn from them. The first one which is suspended here [indicated] simply consists of two flat discs of iron, with a groove between them. In the groove is a coil of iron wire. I shall pass an electric current through the wire, and now it has become a powerful magnet able to support a very heavy weight. When we look at the small size of the magnet and the considerable weight supported, it is most striking. This is the most powerful electro-magnet I have seen for its size. There is another electro-magnet of a different form. This is a horseshoe of iron, round which are coils of wire. At the present moment it has no influence whatever. It is not magnetised at all. Only as soon as contact is made completing the electric circuit you see it requires considerable force to lift off the armature. [Shown.] Now I will connect the two poles by means of this keeper, and then the force with which it attracts is something enormous. I can lift the magnet bodily up by this keeper. When I first had this magnet I was showing an experiment, and I told the audience that as soon as the current ceased to circulate in this way the magnetism would disappear. But to my astonishment on trying it I found it did not disappear at all. There is no current passing through the wire at present, but still the iron attracts the keeper. If, however, I force that iron keeper off, the magnetism absolutely disappears. As a matter of fact, this piece of iron is so remarkably soft that the magnetic induction continuously taking place through the iron must retain this arrangement actually after the magnetising force has been removed. I will give an experiment which suffices to show that when the current disappears the magnetism disappears—that is, if you let the keeper only just touch the two poles of the magnet. As soon as the current stops the magnetism stops too. But when I have the iron formed in a complete ring, so that all the molecules are end to end, it retains its strength after the current has ceased. There is another interesting experiment in which instead of the solid keeper I use a mass of horseshoe nails, which form a bridge from one pole of the magnet to the other, and which present a curious appearance of rigidity; but directly the current is broken off they all part. Faraday, when he was engaged in his brilliant researches in magnetism was accustomed to study the nature of induction and the direction of magnetic induction in space by means of iron filings. I have here a small horseshoe magnet, and I shall project its image on the screen. Then I shall dust the magnet over with iron filings, and you will see the direction in which they lie. Each little piece of iron

Digitized by Google

filing is converted temporarily by the force of this magnet into a magnet itself, and it settles itself in the direction which the inducing force of the magnet tends to give to it. [Shown.] You notice these beautiful curves crossing the poles, which come out more clearly when I tap the glass gently, thus, so as to allow the filings to arrange themselves. In the first place, you see there is always a tendency for the curves to go from the north pole to the south pole. At every point the direction of the filings indicates the direction in which induction is taking place at that particular point. I am not going very far into the question of these lines to-day, but Faraday thought a great deal about these lines of force, and the arrangement he used is of very material aid to understand some of the more difficult problems of electricity which we shall be coming to in the succeeding lectures. If we suppose that a magnet does consist of little pieces of iron with north and south polarity going all the way round, then these iron filings continue the chain, and we have a continuous line of force going right through the magnet and from one pole to the other through space. Others only go part of the way through the iron; they emerge at the sides and come back across the intervening space, re-entering the iron at a point symmetrical with that at which they emerged. But by a study of the direction of these lines of force we are able to get a great insight not only into the theory of magnetism, but into the magneto-electric phenomena which we shall be having presently. I will now throw on the screen another illustration of the same kind, in which I have unlike poles passing each other, and you will see the direction which the lines of force will take when we strew the iron filings there. [Shown.] The general tendency is to cause the lines of force to cross from the north pole to the south pole, not only in a direction straight across, but also in every direction in space. They may take all sorts of different directions, but they are always passing from one pole to the other; the lines, however, never cross one another. The lines of force thus go right through the iron, and it is very important in the conception of lines of force to retain that notion that these lines are continued through the iron, and that this arrangement of molecules, of which I have spoken, is really existing in the iron. This is a very beautiful means of studying the phenomena of induction, and the condition of the magnetic field in the neighbourhood of the magnet. I have been speaking about these ultimate small particles of iron as being magnetic in themselves, and I should mention here a further theory, or hypothesis, which has been advanced to account for the existence of magnetism in these ultimate molecules. This is a theory which the great French philosopher, Ampère, proposed. He suggested that a molecule of iron is nothing more nor less than a circular current of electricity. If a current of electricity could be created in a circular piece of metal, and if that metal offered no resistance to the current passing, that current of electricity would go on for ever, and what Ampère suggested really amounted to this, that a molecule of iron is a perfect conductor of electricity in which an electric current had been established when it was created, and, consequently, the electric currents are going on continually circulating in those molecules. I can show you this much that if we had a circular current of electricity the action would be such as Ampère described. Here I have a coil of wire, the two ends of which are attached, one to a piece of copper and the other to a piece of zinc. I shall dip this coil into a vessel which is floating in a glass dish. Now this coil of wire has a current of electricity in it because the metal is dipping into a solution of acid and water, and we find that the coil takes up a position so that its axis is in the direction of the magnetic meridian. So long as there is a current of electricity passing through it I can show you that the action of the magnet upon it is similar to the action of the magnet upon another freely suspended magnet. I can do that by means of this bar magnet I employ, and according to the side of the coil on which I approach that pole. [Experiment.] You see now it turns round and presents the other face towards me. I can attract the whole thing bodily towards the side of the vessel. The other pole will attract the other side of the coil. Thus, whatever magnetic force I have in the end of this suspended coil it will always tend to set itself with its axis parallel to the magnetising force in the same manner as a freely suspended compass needle would do. Finally, I may force the coil to pause over the bar of iron, and to run along the whole length of it, showing the different series of actions which are exercised between the magnetic bar and the circular coil, which has a current of electricity passing through it. This is the typical magnetic molecule, which Ampère suggested as being the true molecule of iron, and if we can conceive of a molecule having a current of electricity revolving round it like that, the whole of the actions of magnetism would take place just as we know them to be. This is what I meant when I said that probably we should find that magnetism is also another development of electricity to that which we were examining in our last lecture.

It was shown first by Joule that when we magnetise an iron bar its length is increased. It has been supposed by some that this is due to the fact that those magnetic molecules of iron are of elongated form, so that when a magnetising force acts on them so as to put their lengths all in the same direction they naturally take up more space lengthwise than if they were all higgledy-piggledy in different directions. Whether that is the true explanation or not I should not like to say. The experiment that Joule showed proved conclusively that iron does expand when it is magnetised. This is a very important experiment, which I believe is destined to give us a great deal of information in the future as to the nature of magnetism. This is an experiment about which we know very little as yet, but a great deal has been done in the course of the last year or two, and the astonishing fact has been discovered by Mr. Bidwell that not only does iron expand when we put it into a magnetic field of a certain strength, but that if we increase the strength of that field and the power of the induction acting on the iron to a considerable extent, we diminish the action on the iron—that is to say, that as we increase the magnetising force, we first get expansion, and afterwards as the force is still further increased we get an absolute contraction, and the contraction is very much greater than the expansion which had been investigated by Joule. I am fortunately able to show you this experiment, which Mr. Bidwell has been kind enough to set up for us, and if he will kindly give me his assistance we will throw upon the screen an image of it by the lime light. I will indicate a part of the arrangement. Here is a piece of iron bar that is fixed at the lower end. At the upper end there is a mirror moving on a pivot, and a lever attachment so connected with the bar that if the piece of iron lengthens it will give motion to the mirror, and a spot of light reflected from it will be seen to change its position. If the iron were to grow shorter the spot of light would be seen to rise up the scale. I will first commence with a comparatively feeble magnetising force. The black line on the scale is a fixed wire reflected by the mirror, and when I pass a current round the iron wire so as to magnetise it with a comparatively feeble current we shall probably see a descent of that line, indicating that the iron has expanded in length. [Experiment.] There is a motion of about an inch and a half or so. I will now ask Mr. Bidwell to put on a stronger current, and you notice the very large contraction indicated by the rising spot of light. This shows the contraction of the iron when we use a sufficiently high magnetising power. This was not noticed by Joule, because he did not use a strong enough current. I will show you that nickel, one of the other magnetic metals, always contracts. I might mention that the total movement is something extremely small, something like a millionth of the total length, and as the piece of wire is only 3in. or 4in. long, the enlargement which we are obliged to have to make it visible is very great; but this mechanical arrangement of Mr. Bidwell is very satisfactory indeed. On introducing the nickel we find a rise of several inches when contact is made. The feebler power that gave expansion with iron gives a small contraction, but on increasing the power we have an enormous rise—that is, an enormous contraction, far greater than the effect we got with iron.

(*To be continued.*)

ELECTRICITY AS A SAFEGUARD AGAINST FIRE.*

The application of electricity to the prevention of fire may conveniently be classed under the following heads:—(1) The application of electricity to summon assistance. (2) The communication from a police or fire station when an alarm is given to the head and branch stations of the fire brigade. (3) Communication from alarm boxes worked automatically to police or fire stations. (4) Automatic apparatus giving an alarm on pyrometrical principles.

Under the first heading we have the system shown here by Captain Davis, the efficiency of which any of you can easily test by taking a pull at his fire bell. This system, now generally adopted all over the world, has been most elaborated in the United States and Canada. There, on an alarm being given, the current causes the doors of the fire station to open; the horses, trained to it, leave the stable and place themselves before the engine; the harness, which is suspended over it, drops on them, and in seven seconds the engine dashes out. Thus in less than a minute after the alarm has been given the first engine might be on the spot. In San Francisco, the brigade, to save a few critical moments, have a boiler in the basement which is connected, by means of an inlet and outlet pipe, with the boiler of the fire engine, the water being always kept at boiling point; the connection between the boilers being broken off electrically by the current giving the alarm.

The second system has been adopted in most large towns in this country, on the Continent and in America. One great advantage of a telegraphic system over a verbal alarm being the possibility of recording particulars of the first indication and subsequent orders given over the wires, which in many large towns are connected with all the telegraph offices, police offices, and the water offices. Fire messages ought undoubtedly to have precedence over all ordinary messages; but except in the case of messages handed in by police officers, I doubt the wisdom of carrying messages free of charge, as has been suggested. Under the third heading we have a system which has secured an earlier and more rapid adoption on the Continent and in America than in this country, and one of the most complete applications of it is the Automatic Fire Telegraph System, the primary object of which is to reduce to a minimum the time intervening between the discovery of a fire and the presence of a brigade on the spot, it being generally conceded that the chances of a fire becoming serious increase at least as the square of the time between the outbreak and the arrival of the brigade, delay meaning rapid increase of heat, the elimination of moisture from surrounding materials, thus rendering them more inflammable and causing the fire rapidly to assume serious proportions. The principle on which the fire telegraph system at present in use is based is the establishing in sufficient numbers, and in easy accessible places, of suitable apparatus by which information of the outbreak of a fire may be communicated by any person to the nearest fire engine or police station, or to a central station from whence immediate orders are issued, and by it a sign may be telegraphed to the central station indicating the street and district where the alarm of fire is given. The apparatus is a simple mechanical contrivance introduced into the telegraph line, through which circulates a permanent current of electricity from the battery in the central station. When brought into action the annunciator breaks the circuit and signals the central station. The breaking of the circuit is caused by the rotation of a contact wheel, the periphery of

* Paper read at the Balloon Society by Mr. Alfred Thompson.

Digitized by Google

which is so shaped that the contact breaking corresponds to a given Morse signal, and each signal to a given district and street of a town. As many of you have seen, the annunciator is protected by a glass front, and placed at street corners, in railway stations and other suitable sites, and printed directions are affixed to it that in case of fire the glass is to be broken and the handle pulled. When this is done the contact wheel rotates and the letter corresponding to the annunciator is transmitted several times in succession to the central fire station, whence orders are telegraphed to the various engine and police stations. In some cases dial instruments have been adopted in connection with these telegraphs ; but a Morse self-starting recorder has, I believe, been found more reliable. The automatic annunciators have, besides the contact wheel, a Morse key, a galvanoscope, and a lightning protector. By means of the key messages can be sent to the stations of the division if required.

It would appear that there is now a general consensus of opinion—1. That towns without fire telegraphs are liable to very high percentage of serious fires, the cause being unquestionably the time lost in calling out the fire brigade. 2. That the employment of fire telegraphs in all cases leads to a decrease of the percentage of serious fires ; and that the more perfect the fire telegraph is, the greater the reduction in the percentage of serious fires.

Another system, termed the "Auto-Kinetic Automatic," claims that it enables uninterrupted messages to be sent at will, as the instrument waits until the first message is delivered before delivering a second, which is analogous to the block system on railways, and obviates the employment of an open circuit, thus saving battery power and the deterioration of underground wires. For some time after the adoption of the Bright telegraph fire system in England certain disadvantages were found in working it ; but these were easily attributable to the fact that the lines were worked by three services, viz., the fire brigade, the police, and the post office, and that the lines were chiefly overhead, and were in some cases intermingled with post office underground wires. To obviate the great difficulty experienced in finding faults in underground wires, an invention of Sir Charles and Mr. E. B. Bright was patented, in 1852, for ascertaining the locality of faults in telegraph conductors by means of a set of varying resistance coils brought successively into a local balancing circuit in connection with a differential galvanometer, the other side of which was joined to a faulty wire, this being continued until the balance of the needle was arrived at, and the distance to the point of fault thus known. Messrs. Brights' system of fire telegraphs has been adopted to some extent in this country.

Mr. Spagnoletti, Ex-President of the Society of Telegraph-Engineers, directed his attention to electric fire alarms. His system is as follows :—At selected points a post is erected, in the top of which is the apparatus. To give an alarm of fire you have to pull a handle ; to get at the handle a pane of glass has to be broken ; when the handle is pulled a bell rings at the post to satisfy the sender of the signal that he has sent it. At the engine house is an instrument with a dial, round which is painted in clear letters the name of each place at which a post is erected ; a pointer travels round the dial (like the minute hand of a clock, only quickly) and stops pointing at the name of the street from which the signal has been sent, on receipt of a signal, which is instantly seen, and attention is also called to it by the ringing of the bell, the engine is despatched, and then the man acknowledges the signal to the "post," sending it by simply pressing in a "plunger" ; this stops his bell ringing and puts the pointer of the instrument to zero ; at the same time it resets the apparatus at the post, and the apparatus at the post acknowledges itself reset by the deflection of a "needle" at the engine house, and is a guarantee to the engine-house man that the whole system is again restored to its proper condition for another signal. By keeping this needle in deflection to the wire, all the posts and apparatus is kept under a constant test showing all is in good and working order ; if anything fails the needle falls perpendicular, and a bell starts ringing to give notice of the faults. I have another system by which the name of the street from which the alarm is sent is dropped in a hole and shown, and a bell is rung at the same time to call attention to the signal. For large buildings, asylums, &c., the system is different. A wire is run round the building, and a loud bell is placed wherever required on the wire ; any number of bells may be put on the one wire ; at certain points as many as desired contact makers are placed from which alarms are sent, and anyone sending a signal from any of these points starts all the bells off, which continue ringing until stopped. A place of meeting, generally the engine house, is arranged, and as soon as the fire bells are heard the brigade all run to the engine house, as does also the person sending the alarm, and he then gives the locality of the fire.

To illustrate the advantage of self acting fire alarms, a case is on record which occurred in New York, where a building was protected by them and had its wires in direct connection with the nearest fire station. A fire started and the thermostats gave the signal. Before it was known to anyone in the building the engine was at the door. The watchman in the building, declaring roundly there was no fire, refused admission. An entrance was forced and a fire quickly extinguished on the fourth floor, where it had started.

I would now like to quote a few statistics, showing results obtained through one application of electricity under heading 4, viz , thermostats or fire detectors. The benefit of a thermostat, or fire detector system, has been most fully recognised in the United States, where in several of the larger cities very large and complete installations have been made of them ; and from returns made a few years ago by the New York Fire Patrol Committee, it was shown that, apart from the number of lives saved, the result of nearly three years' working of these self-acting alarms had been the reduction of three-fourths of the loss to property in the case of fires which started on premises protected by them. The insurance losses paid on fires in buildings so protected, and which were detected and automatically noted by the apparatus, amounted to $396,909. The amount insured on these buildings and their contents amounted to $7,031,000, the proportion of loss to insurance in these cases being only about 5½ per cent. On the other hand, the insurance losses on risks in the same class of buildings not so fitted was no less than $4,530,928, as against an insurance of $18,990,901, or a loss to insurance of nearly 24 per cent. And it is well to remember in this relation that the means for extinguishing were the same in both cases, the difference of about 75 per cent. in favour of the electrically protected premises being solely due to the rapidity to which the alarm was given by the automatically acting thermostats. In English money the saving in the case of the buildings first referred to was £258,000, and had the unprotected buildings, in which fires occurred, been protected, the saving to the insurance offices would have amounted to £692,000. The insurance companies ultimately woke up to the force of the above facts, and, after the American companies had offered large abatements in premiums on buildings fitted with thermostats, the English companies insuring property in America speedily followed suit.

I now turn for a moment to the introduction of automatic mechanical fire extinguishers, of which we have those of Grinnell and Parmillee, in America ; Victor Van Keer Bergen, in Belgium ; Alfred James Eastwood and Messrs. Dowson and Taylor in this country. The purpose aimed at by these gentlemen was similar to that which is obtained by the system patented by myself and Mr. Ritchie in the early part of this year. And, regarded as mechanical contrivances, their inventions are deserving of every praise. Statistics collated by Mr. Woodbury from the books of the Factory Mutual Insurance Companies of New England show that during a period of eight years from January, 1877, to January, 1885, the number of fires occurring in buildings not protected by sprinklers was 553 ; that the number of fires protected by sprinklers was 195, giving a total of 748 ; that the average loss in the 553 fires (unprotected) was £1,624, as against an average in the case of the 195 protected buildings of only £70—a difference in favour of the latter of £1,554. The advantage of using fire sprinklers will thus be perfectly obvious. Under the heading No. 4, I class the automatic "electric" fire extinguisher, a model of which you may observe on the table before you ; and I ought to mention that in patenting this invention the consideration that has had most weight with us is the very remarkable results which have, as I have endeavoured to show you, followed when merely mechanical contrivances have been superseded by those electrical. We have seen how electric fire alarms have gradually relegated to the back ground pre existing methods of working ; and if the results, as ascertained from careful statistics, show the vast superiority of all electric fire alarms, it is with stronger reason to be anticipated that the apparatus which you see before you, and which not only gives a fire alarm at any desired point, but shows on an annunciator the the exact site of the fire, and at once sets to work to grapple with the fire independently of all outside means and pending their arrival, has an important future before it.

The advantages of the automatic electric fire extinguisher are :—1. Its instantaneous action on the occurrence of a fire, either during day or night. 2. Its perfect automatic action and independence of human aid, more especially where fumes of smoke might endanger human life. 3. The confinement of a fire to the point where it originated. 4. The discharge of water is confined to the site of the fire, or, if desired, can be extended to an area immediately surrounding it by bringing into action extinguishers in its immediate vicinity. 5. It admits of frequent testing to prove it is in working order, without expense or inconvenience of any kind. 6. It admits of automatically turning the water into the pipes after it has, through the action of the thermostat, been run out automatically on a fall in temperature to near freezing point.

Before concluding I would like to say a word or two on two other branches of electricity which bear upon this question, viz., telephones and electric light. I am not aware that telephones have ever been practically used in connection with fire telegraph systems ; but no one can doubt the great use that may be made of them in summoning assistance to a fire. I also claim for electric light that it is essentially a preventer of fire. It imparts very little heat as compared with other illuminants, and cannot in the case of incandescent lighting be brought into contact with inflammable material. To illustrate this an incandescent lamp fully incandesced may be carried about amongst inflammable gases without igniting them, or be suddenly broken when enveloped in muslin without setting fire to it.

PHYSICAL SOCIETY.—May 8th.

Prof. H. McLEOD, F.R.S., Vice-President, in the chair.

Mr. W. A. Price was elected a member of the Society. The following communications were read. "On a Modified Form of Wheatstone's Rheostat," by Mr. SHELFORD BIDWELL. A wire is coiled upon a non-conducting cylinder as in the ordinary forms of rheostat, one end of the wire being in contact with the brass axle of the cylinder. A screw is cut upon the axle, the pitch being equal to the distance between the consecutive turns of the wire, and this, working in a fixed nut, causes the whole cylinder to travel in the direction of its axis. A fixed spring bears upon the wire at a convenient point, and by the travelling motion of the cylinder this point of contact remains fixed in space, and the effect of turning the cylinder is to introduce more or less resistance between the spring and the brass axle. Binding screws on the base of the instrument are in contact with the nut and the bearing spring. Though this arrangement has several obvious advantages over the usual forms, Mr. Bidwell does not recommend it in cases where it is required to introduce a known resistance ; but where it is important to adjust a resistance to a nicety, or to cause a continuous variation, it is of great use. Prof. PERRY, remarking upon the importance of being able to vary a resistance gradually, described an instrument he had used with advantage. A number of plates of gas

Digitized by Google

carbon are placed between two parallel copper plates, one of which is fixed, and the other adjustable by a screw; by applying pressure by means of the screw the resistance between the plates can be varied uniformly and regularly from 2 to 10 ohms, beyond which point the increase is very rapid.

On a "Theorem Relating to Curved Diffraction Gratings," by Mr. WALTER BAILY. In a paper read before the Society in Jan. 1883, the author showed that if a plane be taken perpendicular to the lines of a curved diffraction grating, and a normal to the grating be taken as the initial line, then the equation

$$\frac{\cos^2\theta}{r} = \frac{\cos\theta}{c} + \frac{1}{d}$$

in which c is the radius of curvature of the grating, and d is an arbitrary constant, gives a curve having the property that if a point of light be placed anywhere upon it, the curve is the locus of the foci of all diffracted rays, whether reflected or transmitted. In the present investigation d is supposed to be greater than c, which allows of the source at light being at infinity. The points where the curve given by the above equation cuts the normal are called the normal foci. There are two of these, one relating to the reflected and the other to the transmitted light, the grating being supposed to consist of a number of opague lines in space. It is then shown that if the grating be supposed to turn about the line in it intersecting the initial line, the normal foci will trace out two parabolas whose common focus is the origin, and common latus rectum is equal to the diameter of curvature of the grating, the parabola for reflected light being convex to the source of light, and that for transmitted light, concave.

"On Some Thermodynamical Relations," Part IV., by Prof. W. RAMSAY and Dr. SYDNEY YOUNG. The first part of this communication deals with Profs. Ayrton and Perry's criticisms upon the previous papers by the authors upon this subject. In the second part a brief review is given of the various attempts that have been made to represent the pressure of a saturated vapour as a function of the temperature.

MAY 22, 1886.—Prof. BALFOUR STEWART, President, in the Chair.

Messrs. C. A. Bell, W. C. Johnson, and James Swinburne were elected members of the Society.

The following communications were read:—"On the Sympathetic Vibrations of Jets," by Mr. CHICHESTER A. BELL. It has been assumed hitherto that a gaseous or liquid jet vibrates under the influence of a limited range of tones only, effective tones being those which do not differ greatly in pitch from the normal or proper tone of the jet, discovered by Savart and Sondhauss. The author has found, however, that when the pressure under which a jet escapes is not too great, the latter is affected by all tones lower than the normal, as well as by some above it. Changes may be excited in a jet of either kind, by vibratory motions of the jet orifice, or of the fluid behind, or external to the orifice. These changes take the form of slight swellings and contractions, which become more pronounced as the fluid travels away from the orifice, and finally cause the jet to break or become discontinuous at a distance which depends upon the intensity of the initial disturbances. At any point within the continuous portion of the jet the successive swellings and expansions represent both the form and the relative intensities of vibrations impressed upon the orifice; and the jet is, therefore, capable of reproducing very complex sounds, such as those of speech and music. A vibrating jet of air does not, however, emit sound when it plays with free air, or into the wide end of a tube communicating with the ear; but when it plays against a very *small* orifice in the end of a hearing tube loud sounds may result. This reproduction is most intense when the hearing orifice is placed in the axis of the jet, just within the breaking point; but becomes gradually feebler as the hearing orifice is moved towards the jet orifice, or out of the line of its axis. Beyond the breaking point the sounds from the jet at first become confused, and finally are lost. A jet of gas, like a liquid jet, only vibrates so as to produce its normal tone when it strikes upon some obstacle which serves to diffuse the disturbances due to impact or throw them back upon the orifice. The vibrations of an air jet are also loudly reproduced as sound when it is directed against a small flame below the apex of the blue zone. Liquid jets are but slightly sensitive to aerial sound-impulses, but become highly sensitive when the jet tube is rigidly attached to a sound board. The vibrations of a jet so mounted are best perceived as sound when the stream strikes upon a rubber membrane tied over the end of a narrow tube which communicates with the ear. For accurate reproduction of speech and sounds in general the jet should be at such a pressure as to respond visibly to a note of about 4,000 vibrations per second, and the membrane should be at such a distance from the orifice that the jet never breaks or becomes discontinuous above its surface. The vibrations of very fine jets of any conducting liquid become loudly audible when a portion of the jet or the "nappe" formed when it strikes upon a flat surface is included in circuit with a battery and a telephone. This may be accomplished by letting the jet impinge on the end of an ebonite rod, through the centre of which passes a platinum wire; the upper end of the rod is surrounded by a short tube or ring of platinum, the upper margin of which forms a continuous slightly convex surface with the exposed end of the central wire and the ebonite. The wire and ring form the terminals of the circuit which is completed through the nappe. Distilled water containing $\frac{1}{300}$th of its volume of pure sulphuric acid is recommended as the jet liquid. The author advances a new theory to account for the growth of the vibratory changes in liquid and gaseous jets.

"On Some Thermodynamical Relations," Part V., by Prof. W. RAMSAY and Dr. S. YOUNG. In Parts I. and II. of this series of papers it was shown that the ratio of the absolute temperatures of any two bodies corresponding to a given vapour pressure bears a simple relation to the ratio at any other pressure, which may be expressed by the equation $R' = R + c(t' - t)$, where R' and R are the two ratios, c is a constant, and t' and t are the temperatures of one of the two bodies. The determination by Schumann (*Pogg. Ann.* N.F. 12, 46) of the vapours of methyl formate and 27 homologous ethers made it possible to compare the vapour pressures of a large number of bodies belonging to the same class. It was found that when the ethers were compared with ethyl acetate, which was taken as the standard, in every case $c = 0$, and therefore $R' = R$. The temperatures corresponding to the three pressures 200, 760, and 1,300mm. are given by Schumann. Taking the mean value of R for those pressures as correct, and recalculating the temperatures, the greatest difference between the found and recalculated temperatures is 0·7°C. The vapour pressures of water or any one of the ethers being accurately known, it is sufficient to determine the boiling point of any ether belonging to this class, in order to construct its vapour pressure curve. The absolute temperatures corresponding to the pressures 200 and 1,300mm. for any ether are $\cdot 89795t$ and $1\cdot 0488t$, where t is the boiling point at normal pressure in absolute temperature.

A gridiron slide rule, by Mr. Stanley, designed by Mr. Thacker, was explained by Mr. C. H Boys. It was equivalent to a slide 60ft. long, and performed multiplication and division with an error not exceeding the 1-40,000th part.

Specimens of safety explosives, and their results in shattering blocks of lead, were exhibited by H. SPRENGEL.

COMPANIES' MEETINGS & REPORTS.

London Platino-Brazilian Telegraph Company (Limited).

The eighth ordinary general meeting of shareholders of this Company was held at the offices of the Company, Winchester House, 50, Old Broad-street, on Monday, 31st May, under the presidency of Mr. John Pender.

The SECRETARY (Mr. Wm. Payton) read the notice convening the meeting and the minutes of the previous meeting, which were confirmed and signed as correct. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen—Before asking you to approve of the first resolution for the adoption of the report and accounts I have to make a few remarks. In the first place, I think it is right to mention that there are several difficulties surrounding us at the present time. Firstly, the telegraphs are suffering from depression of trade, which may be said to exist all over the world, and at the present time it is felt to a very severe extent in the Republic of Uruguay. Another difficulty is to obtain payment from the Government of that country. We are on perfectly good terms with the Government, and they are doing everything they possibly can to meet our requirements. Previous to this meeting we sent a telegram to our agent at Monte Video, in which we drew attention to the fact that our meeting was about to be held, and it would be necessary that I should have some facts and figures to put before the shareholders as to the debt owing to to us by the Government, and we received the following reply:—Extract from Señor Lanza, our manager's letter dated 29th April, 1886: "On the 21st I replied, saying that the Finance Minister was absent, and would not return until the following Monday, adding that I would communicate the result of my interview. The very same day that I communicated the foregoing to London I spoke to the President, to whom I translated Mr. Pender's telegram, and, after reminding him of the important services rendered lately by these lines, nevertheless without obtaining due attention to our claims, he answered more or less as follows: 'Already the Captain-General of the forces by land and sea has manifested to me that the line under your management has rendered the most important services towards the pacification of the country, working day and night with the most exceptional regularity and decided good will, and precisely for these reasons it is doubly painful for me to find myself unable to recompense such services by paying their full import. Soon, I expect, the Chambers will provide the means necessary for the payment of all back accounts, and then your Company will be immediately attended to. With respect to accounts appertaining to my administration, you should see the Finance Minister, to whom I will recommend immediate attention to you.' It was not until yesterday that I succeeded to speak with the Finance Minister, to whom also I translated Mr. Pender's telegrams, &c. He was more explicit in his reply, telling me 'that he could not guarantee the regular payment of accounts, posterior to the month of March, for the reason that the claims to attend to are very numerous, and the resources very few; but, nevertheless, in attention to the important services rendered by our line, he would do everything possible to favour me," and to-day they paid me $1,500 on account, which I communicated to the Chairman in the following telegram:—'Interviewed Finance Minister. Chambers discussing project to pay back accounts with bonds bearing high interest and amortization. Collected to-day $1,500. Money scarce; difficult job collecting.'" Then there is a telegram received from the same quarter, dated 14th May, which says:—"Law sanctioned creating new bonds bearing 8 per cent. interest and 4 per cent. amortization. Government service for February, March, and April reached $28,000. With $12,000 previously owing, makes a total of $40,000. This amount almost entirely will be paid with new stock at par. By first mail remitting £500." That shows you, gentlemen, pretty clearly the position of the Government. They are very desirous to pay what they owe us, and I believe they will continue to do their best towards this end. The second element of difficulty was referred to in our report for 1884 as follows:—"A difference has arisen between the Directors of this Company and the Western and Brazilian Company with respect to this Company's

Digitized by Google

proportion of the receipts for telegrams sent since the reduction of tariff. Pending adjustment there has been brought into the accounts only the amount credited to this Company by the Western and Brazilian Company." The amount in dispute has been kept in suspense in the accounts; and it may yet have to be settled in a court of law. The third difficulty has been the loss of traffic on account of the competition of the Brazilian Government land-lines with the cables, which point is referred to in the report now before the shareholders:—"The competition for South American traffic with the cables of the North Atlantic and of the West Coast of America Companies has continued during the past year, and has seriously diminished the revenue of the Western and Brazilian Company, in which this Company is so largely interested." Our receipts from the Western and Brazilian Company in the past year amount to £8,614; in the previous year they were £10,655, and in 1883 they were £12,638, so we have not far to seek for the cause of the diminution in our dividend. As regards the future, there are negotiations pending. It is understood that the Chambers of Brazil have adopted a principle on which they will be prepared to make an offer to the companies interested in Brazilian telegraphs. The Western and Brazilian Company is the first company to be treated with, because they have the larger interest, but no arrangement can be come to without the concurrence of this Company. Now, gentlemen, I have shown you exactly the position that we are in now. We are suffering from depression of trade, we are suffering from extreme competition, and we have been suffering to some extent from the non-payment of our accounts. As to the first, I have given you full information; as to the competition, I suppose that will, as all competitions do, wear itself out, probably in a shorter time than we imagine, more particularly if the negotiations pending between the Western Brazilian Company and the Brazilian Government come to a successful issue. But whatever the result may be, we shall be able more or less to control those negotiations. I believe we have a right to do so, and in controlling them we should, of course, look after the interests of the Platino-Brazilian Company. With these remarks I beg to move the following resolution:—"That the report and accounts for the year ended March 31st, 1886, submitted to this meeting be, and they are hereby received and adopted; and that a dividend of 1s. per share be declared payable this day, free of income-tax; making with the interim dividend already paid, a distribution at the rate of 1 per cent. per annum." I might mention that since we assumed the direction of this Company we have paid altogether £52,600 in dividends, or an average of 2 per cent. per annum. We were urged to take up the work, and although we have not been able to pay you a large dividend, we have been able to give you at least something out of what appeared at the time we took office to be a total wreck.

Mr. JOHN HOLLOCOMBE seconded the resolution, which was carried unanimously.

On the motion of Mr. HOLLOCOMBE, seconded by Mr. PAVY, Mr. John Pender was unanimously re-elected a Director of the Company.

The CHAIRMAN: I am very much obliged to you for this renewed mark of your confidence. I wish I could say that there is a very brilliant future before us. All that I can say is that in any arrangements that have to be made we shall take very good care that the interests of the shareholders of the Platino-Brazilian Company are fairly protected. At all events we shall not take any definite steps towards a settlement without first calling the shareholders together.

Mr. WM. FORD then proposed, and Mr. J. W. FULLER seconded, "That Messrs. Deloitte, Dever, Griffiths and Co. be, and they are hereby re-elected auditors of the Company at a remuneration of £25 for the year."

The motion having been agreed to, a vote of thanks was accorded to Mr. Pender for presiding, and the proceedings terminated.

The West Coast of America Telegraph Company (Limited).

The ninth ordinary general meeting of this Company was held on the 2nd inst., at 50, Old Broad-street, under the presidency of Mr. Alfred Marshall.

The SECRETARY (Mr. F. L. Robinson) read the notice convening the meeting and the minutes of the last meeting. The report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, I have very few remarks to add to the report which you have received, and which shows the accounts of the previous year. You will remark that there is very slight difference in the working expenses, and the difference there is in the West Coast expenses is a saving in the course of the year. We hope that we may be able to maintain our expenditure at a similar low rate for the future. The "Retriever's" expenses are about £300 higher than in the previous year. This is a slightly varying item; sometimes the vessel may be docked at the end of the year, and sometimes at the beginning of the following year. This will account for such a difference as that which I have mentioned. I now come to the item of maintenance of cables. We have been very fortunate in not being called upon to make any extensive repairs, and on that item alone we have made a saving of £1,600. This we have thought prudent to take into consideration in recommending the addition of a comparatively large sum to the reserve, and we have no doubt that this will meet with the approval of all our shareholders. The gross earnings of the Company show, unfortunately, a falling off compared with the previous year. That is entirely, or almost entirely, attributable to bad trade. A great part of that was produced by the war that has been going on between Chili and Peru, and which has, of course, impoverished the people of that country very much. We can only look to an improvement in this direction gradually. There is one item which calls for explanation. It is in the interest account. You will see there is an amount of £381 placed to the credit, whereas it would naturally appear that the investment of £10,000 in our reserve at 8 per cent. would produce a larger sum. At the instruction of our auditors we have debited this account with loss on interest incurred by cable transfers. We have up to now adopted the plan of remitting money by cable transfer instead of by bills. This costs us a difference in the exchange, as bankers charge a higher rate of exchange, and at the same time we lose the difference of time between the purchase of the bill and the time when it arrives in England, and the three months which the bill has to run. We are taking measures to avoid this loss in future by resuming remittances by bills from the present moment. In fact, we are instructing our manager to-day to make this alteration immediately. I may inform you that the reports of our manager are very satisfactory in regard to the electrical condition and thorough working order of our lines, and we are doing everything in our power to keep them in satisfactory order. Our staff are, I believe, quite exceptionally efficient. We get information about all the errors that are committed in regard to messages sent to Valparaiso and coming therefrom, and every complaint that is made is investigated. It will be very satisfactory to you to hear that the last report we have received shows that of the few errors that were made not one for the last month for which we have received the report was committed by our staff. We keep a very close watch on the working of our men, and we hope we may continue to secure such good working in the future. With these remarks I propose the reception and adoption of the report. If any gentlemen present wishes to make any inquiries about any matter connected with the Company we shall be very happy to give any information in our power.

Mr. TAYLOR said that there was a saving, apparently, in the accounts of some £1,500, being a reduction in the West Coast expenses; but if they had not debited the expense of the remittances to interest account the West Coast expenses would have been some £400 or £500 more. The shareholders must therefore not consider that the West Coast expenses had been reduced by £1,500, but by about £1,000.

The CHAIRMAN stated that that was so. It was merely a matter of figures.

Mr. TAYLOR: Yes, but you take credit for £1,500 saved, and there is really only a saving of about £1,000.

The CHAIRMAN replied that the same principle was adopted last year, so that the saving really was as large as was shown.

Mr. TAYLOR admitted that in that case the saving was £1,500.

The CHAIRMAN added that he had referred to the matter because one or two questions had been asked him, and he had thought it would be better to answer them at the meeting.

Mr. LAMONT inquired whether the receipts this year were showing any improvement?

The CHAIRMAN said he was sorry to state that they were not showing an improvement. The total traffic up to May 31 had been £16,700 against £20,800 last year.

Mr. LAMONT: That is going the wrong way altogether.

The CHAIRMAN: In the last month there seems to have been a little sign of reaction, but very slight, and we hope that that will continue.

Mr. LAMONT: Peru has got a settled Government now.

The CHAIRMAN: Yes, settled in the same sense as before. Chili has got a settled Government, and has not had a revolution since 1859, which is saying a great deal for countries of that kind.

Mr. LAMONT thought that the prospects of the Company were not very brilliant at the present moment.

The CHAIRMAN: No; but we must hope for the best. We keep our lines in the best order ready to expand at any moment.

Mr. TAYLOR urged the Directors to do all they could to keep the expenses of the steamer down. The insurance was £1,164. That bore on the value of the steamer in the capital account, and also on the remarks of Mr. Weise in the auditor's report:—"No allowance has been made for the depreciation of the steamship, it being considered the vessel is of the full value at which it stands in the accounts." He did not know who considered her of full value. He knew he might be told that she was a special vessel, but no business man would think otherwise than that she could be renewed at from £3,000 to £5,000 less. He therefore did not see the necessity of insuring her at more than her value, and, moreover, by doing so they were breaking the law.

The CHAIRMAN said he had already explained the increase in the expenses of the vessel. She was insured for £21,000, but she cost a great deal more.

Mr. MASON said that Mr. Taylor's remarks might be applied to every shipping company in the country. There was no shipping company whose capital was represented by the value of the ships.

Mr. TAYLOR was understood to say that shipping companies provided for depreciation.

The CHAIRMAN: We believe that this vessel cost a great deal more than she is insured for.

Mr. TAYLOR said he had always understood that nothing had been written off her value.

The CHAIRMAN: We might this year have written off a certain amount from the value of the "Retriever," and put less to reserve.

Mr. TAYLOR: But why insure her at £21,000 when, if that was her cost, I say she could be got for £4,000 less to-day? I do not find fault; I am giving advice.

The CHAIRMAN stated that in case of an interruption it would be to the benefit of the Company to have insured for so much.

Mr. TAYLOR: But the law says that you may not insure a vessel for more than its value.

The CHAIRMAN: It would be a loss to the Company if the vessel were lost.

Digitized by Google

Mr. TAYLOR: I think not, as she could be replaced for less.

The CHAIRMAN: We will take what you say into consideration.

Mr. TAYLOR thought that 5 per cent. at least ought to be written off for depreciation of the vessel.

Mr. T. F. CAMPBELL then seconded the motion, which was carried unanimously.

Mr. TAYLOR afterwards expressed his great regret at the death of Mr. Robinson Kendal, the late Chairman of the Company, whose place, however, he was glad to see so ably filled. He had every confidence in the well-being of the Company, provided that political and other matters over which the Directors could have no control did not intervene.

Mr. CAMPBELL said that the Company had been very fortunate in securing the services of Mr. Marshall to fill the vacancy which had been caused by the lamented death of Mr. Kendal. He proposed the re-election of Mr. Marshall and of Mr. Henry Roberts.

Mr. W. E MAC ANDREW seconded the motion, which was carried unanimously.

Mr. MASON then proposed the re-election of the auditor, M. J. Weise (of the firm of Messrs. Turquand, Youngs, and Co.) He was, he said, very glad to have heard the explanation which the Chairman had given as to the item of interest account, which had attracted a good deal of attention on the part of some of the shareholders.

Mr. TAYLOR seconded the resolution, and it was carried unanimously.

On the motion of Mr. MASON, seconded by Mr. TOWLE, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN, in reply, said that the Directors would do everything in their power to make the Company prosperous. Having been himself resident on the coast—in fact, having spent the best years of his life on the coast—he was personally acquainted with the localities and with the large majority of the Company's customers. He also knew what kind of business they had, having worked for about 16 years on the coast.

The proceedings then terminated.

The Consolidated Telephone Construction and Maintenance Company (Limited).

Report of the Directors to be presented at the fifth general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, E C., on Thursday, the 10th June, at 12 o'clock noon :—

The Directors beg to lay before the shareholders a statement of accounts and balance-sheet for the year ending 31st March, 1886. Out of the balance of £5,208. 18s. 4d. remaining to the credit of the revenue account to March 31st, 1885, a dividend of 2½ per cent. was paid to the share holders in June ; and £310 has been paid towards a settlement of the late Directors' fees, which were in abeyance. The gross profits of the year amounted to £13,473. 16s. 2d. After deducting the working expenses, £3.695. 11s. 1d., together with £500 written off goodwill and patents, and £359. 3s. at 10 per cent. depreciation of plant, machinery, and office furniture, there remains a balance of £8,919. 2s. 1d. To this must be added £682. 19s. 7d. balance from the year 1884-5, which makes a total of £9,602. 1s. 8d. Out of this a dividend of 2½ per cent. was paid in November last, amounting to £4,215. 18s. 9d. ; and your Directors now recommend that a further dividend of 2½ per cent. be paid, leaving a balance of £1,170 4s. 2d. to be carried forward to the next year's account. Your Board is happy to state that the relations between the United Telephone Company and your Company continue to be of a most satisfactory nature. Your Directors are pleased to be able to state that the the manufacturing business shows a steady increase, the Company having secured many new customers abroad, in addition to the usual orders from the United Telephone Company. They are also gratified to report that more orders have been given by the United Telephone Company and its subsidiary companies for non-patented articles. This result has been mainly achieved through the improvement in the various articles manufactured by your Company. Agencies have been started in Madrid, Cadiz, and Naples, and it is in contemplation to send a representative to the Continent with a view of opening up fresh ground for the sale of instruments. An amount of £103. 9s. 7d. has been obtained in reduction of income-tax, which was under appeal when the previous accounts were issued, in addition to which the further sum of £187. 18s. 6d., which was reserved in last year's account, pending the appeal, has now been brought to the credit of the year's account, making the £291. 8s. 1d. shown in the present accounts. A compromise has been arrived at with certain of the late Directors in connection with their fees. Sir Alexander Armstrong and Mr. Bigelow have voluntarily relinquished their claims, and the claims of Messrs. Carnegy and Spensley have been settled for the total sum of £310. Colonel Gouraud, notwithstanding the circular sent round by him to the shareholders in July, 1884, stating that he voluntarily relinquished his fees, has commenced an action against your Company for the sum of £1,426 15s., and your Board have instructed the Company's solicitors to defend the action. This leaves Sir Julius Vogel alone unaccounted for, but against this gentleman the Company have a large claim in respect of the allotment of shares at the outset of the Company's history. Your Directors will ask permission to join the Edison-Gower Bell Telephone Company in an action against the Bell Telephone Company of Antwerp and the Compagnie Belge du Telephone Bell. These companies are largely infringing the Edison patent in Belgium, and your legal advisers state that there is a good case against them. The debts due by the subsidiary companies on March 31st, 1885, having been either settled or converted into shares or debentures, estimated by the Directors to be of the full value stated in the balance-sheet, the reserve of £6,000. which has stood in the account of the Company against these assets, is no longer required for this purpose. They have, therefore, with the approval of the auditors, passed this amount to the credit of a reserve fund for the general purposes of the Company. For the present this amount is invested in the general assets. The most important event which has occurred in connection with the subsidiary companies is the signing of a preliminary agreement between the River Plate Telephone Company and the opposing company, the United Telephone Company of the River Plate. The result of an amalgamation after four years' hard fighting cannot be otherwise than beneficial to your Company. The business of the several subsidiary companies in which this Company is largely interested continues to make very satisfactory progress. The Telephone Company of Austria at the end of March, 1885, had 918 subscribers, paying a gross annual rental of £6,433. At the end of March, 1886, there were 1,373 subscribers, representing a gross annual rental of £9,258. This shows an increase of 455 subscribers, and of £2,825 on the annual rental. There also were 172 persons wishing to join the exchanges, with a gross annual rental of about £1,240. These are being connected up as fast as possible. With regard to the Edison-Gower Bell Telephone Company, at the end of March, 1885, the two exchanges of Lisbon and Oporto had 870 subscribers, paying a gross annual rental of £5,380 ; and at the end of March, 1886, there were 1,105 subscribers, paying a gross annual rental of £6,80). This shows an increase of 235 subscribers, and of £1,420 rental during the year. As to the River Plate Telephone Company, on the 28th February, 1885, the number of subscribers to the exchanges of Buenos Ayres and Monte Video was 1,858, with a gross annual rental of £29,400, and on the 28th February, 1886, there were 2,181 subscribers, paying a gross annual rental of £35,107. This shows an increase of 323 subscribers and £5,707 gross income. The total increase in the exchanges, as compared with 1885 and 1835, may therefore thus be stated :—

	Subscribers.	Rental.
Telephone Company of Austria	455	£2,825
Edison Gower-Bell Telephone Company ...	235	£1,420
River Plate Telephone Company	323	£5,707
Total increase for the year.....	1,013	£9,952

In accordance with the Articles of Association the following Directors retire by rotation, and being eligible, offer themselves for re-election, viz., Sir Alexander Armstrong, A. H. Baker, Esq., and H. Grëwing, Esq. The auditors, J. G. Griffiths, Esq., F.C.A. (Messrs. Deloitte, Dever, Griffiths, and Co.), and A. E. Green, Esq., also retire, and offer themselves for re-election.

NOTES.

MR. CYRUS W. FIELD.—This gentleman is a passenger by the "Umbria," which left New York for Liverpool on Tuesday.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 4th inst amounted to £2,660.

PHYSICAL SOCIETY.—A paper by Mr. W. Emmott and Mr. W. Ackroyd, on electric fire damp indicators, is announced for reading on Saturday, June 12.

THE OLD TELEGRAPH COMPANIES.—The annual social gathering of officers of the old Telegraph Companies took place at the Mitre, Hampton Court, on Wednesday last.

FINSBURY TECHNICAL COLLEGE.—We are informed that the students of the Finsbury Technical College intend holding their second annual *conversazione* on the evening of July 2.

PERSONAL.—Mr. W. H. Fleming, late of Baliol-chambers, has been appointed manager of the electrical department of Messrs. Marshall and Co., Custom House-arcade, Liverpool.

SOCIETY OF ARTS.—The *conversazione* of this society will be held, by permission of the Royal Commission, at the Colonial and Indian Exhibition, South Kensington, on Friday, the 16th of July.

PARIS.—According to the *Bulletin International de l'Electricité*, MM. Siemens have decided to close their works in Paris. The business will be carried on direct from one of the other houses of this firm.

AN ELECTRICAL MONOPOLY.—The Mexican *Diario Official* publishes a decree granting an exclusive privilege for ten years to Messrs. E. H. and A. H. Cowles for their process of reducing metals by electricity.

GREAT NORTHERN TELEGRAPH COMPANY.—The receipts of this company in May were £22,480, and the receipts for the period of January to the 30th May, £100,960; for the corresponding months in 1885 £118,000, and 1884 £106,560.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 4th June were £2,093, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

ROYAL SOCIETY.—At the second *soirée* of this society, held on Wednesday last, the telephone room was put into communication with the Savoy Theatre, and a large supply of instruments were provided for hearing the performance of "The Mikado."

BOOKS RECEIVED.—"Electric Transmission of Energy." By Gisbert Kapp. London: Whittaker and Co. and George Bell and Sons.—The second edition of "Traité Practique d'Electricité Industrielle," par MM. Cadiat et Dubost. Paris: Baudry et Cie.

EARTHQUAKES.—Several shocks of earthquake have been felt lately in the island of Chios and in the Erythrian Peninsula, but no damage has been done.—A smart shock of earthquake was felt in Guernsey on Monday last. Buildings in different parts of the island were shaken.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of May was 3,744, estimated to produce £3,050, against 4,474 messages, producing £3,736 in the corresponding month of last year. The traffic receipts for the month of February, estimated at £2,750, realised £2,771.

MONTPELIER.—A company has recently been formed in Montpelier, under the name of the Standard Light and Power Manufacturing Company, having for its object the furnishing of electric light for places of business in the town and such private houses as can be reached. We understand that an exhibition of electric light will shortly be made at Montpelier.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company on Wednesday last declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended March 31st, 1886, payable on the 24th inst. The books of the company will be closed from the 17th to the 23rd inst., both days inclusive.

CONVENIENCE AND INCONVENIENCE.—Even in India, where one would have thought the requirements of the military were almost supreme, it does not always happen that their desires are consulted, for we find that a telegraph office has been opened in the native city of Aurungabad, about two miles from the military cantonment, much, it is said, to the inconvenience of the military element.

COPPER WIRE FOR TELEPHONES.—The Central District and Printing Telegraph Company, which controls the Bell telephone patents in Western Pennsylvania, is making some important changes in its lines of wire. At present it is replacing some 200 miles of wire throughout Pittsburg with a hard copper No. 14 wire that costs $25 a mile. The iron wire that is being removed cost $9 a mile.

ELECTRICITY IN MEDICINE.—It is interesting to note how largely electrical appliances are being used in the medical profession. Constant readers of the *Lancet* will not fail to see week by week discussions as to the best methods of using electricity in surgical and in medical cases. We believe there exists a widespread belief among the profession that a grand future exists for electricity in the alleviation of suffering.

ELECTRIC LIGHTING ACT AMENDMENT.—After an exhaustive inquiry, the Select Committee of the House of Lords appointed to consider the three Bills introduced for the purpose of amending the Electric Lighting Act of 1882 have resolved to recommend the adoption, subject to certain modifications, of the measure brought in, on behalf of the Board of Trade, by Lord Houghton. The Bills of Viscount Bury and Lord Rayleigh are thrown out. The full text of Lord Houghton's Bill will be found in another column.

ELECTRIC LIGHT ON STEAMERS.—The General Trans-Atlantic Company of France have constructed specially for its service between Havre and New York four new express packets, all of which are lighted by electricity. Each vessel is provided with 620 incandescent lamps fed by two large dynamos with compound motor, and passengers may in their cabins turn off and on the light at pleasure. To guard against any accident during the voyage a spare dynamo and motor are kept in readiness.

THE ELECTRIC LIGHT AT LE CONSERVATOIRE DES ARTS-ET-METIERS.—This institution has been illuminated recently by the electric light. The installation, which has been carried out under the direction of M. Gustave Tresca, consists of 10 arc lamps of the well-known Cance system, which are distributed as follows:—6 in the library, 3 in the amphitheatre, and 1 in the machine room. This important change in the lighting of the building has been much appreciated, especially by the frequenters of the library.

THE UNITED TELEPHONE COMPANY.—The directors of this company, subject to audit and after making provision for

Digitized by Google

depreciation, &c., recommend a dividend for the half year ended the 30th of April at the rate of 9s. per fully paid share, part-paid shares receiving in proportion, making with the interim dividend paid on the 13th of November a total for the twelve months of 13 per cent. per annum, carrying forward a substantial sum to reserve.

TELEGRAPHING EXTRAORDINARY.—The total number of private telegraph messages sent out from the House of Commons during Monday's sitting was 1,387. There were, besides, some 308 Press messages. The total number of messages received during the day for members of Parliament was 395. Between half-past one and half-past two on Tuesday morning, when the division on the Home Rule Bill took place, more than 770 messages were despatched from the telegraph office at the House of Commons.

ELECTRIC LIGHTING IN A POWDER MAGAZINE.—For the last twelve months the powder magazine at Toulouse has been provided with the electric light, which has given the greatest satisfaction. The installation consists of a hundred incandescent lamps (Edison) conveniently distributed over the works, one Mondos arc lamp being erected in the yard. A hydraulic motor is used to work the Siemens dynamos, which send the electric current through underground wires enclosed in earthenware pipes, thus obviating the possibility of any accident.

THE "VICTORIA."—Messrs. Henry Bennett and Co., of Bothwell-street, Glasgow, have secured the lighting of the new passenger saloon steamer "Victoria," launched recently from the yard of Messrs. Blackwood and Gordon, Port Glasgow. This steamer has been built to the order of Capt. Campbell, of Wemyss Bay, and when finished will rank as one of the finest saloon steamers on the Clyde. Capt. Campbell deserves the credit of being the first to light his steamer throughout with the electric light. We have no doubt the other steamboat owners will follow Capt. Campbell's lead in this matter.

THE ELECTRIC LIGHT IN HOSPITALS.—A fresh proof of the growing popularity of the electric light in Paris is to be found in the fact that some interesting experiments are just now being made to light the hospitals there by electricity. A few of these institutions have already been furnished with an installation of incandescent lamps, not only in the operating theatres but in the sick wards, with such satisfactory results from a hygienic point of view that there is little doubt that before long the system will be generally adopted by the *Administration de l'Assistance publique.*

ELECTRICAL TRANSMISSION OF POWER.—The Cannon Foundry at Bourges has two 20-ton cranes for the handling of very large ordnance. Each of these is worked by a special electrical motor, with current furnished by a single generator. The power is transmitted a distance of 120 metres, and is about 13 horse-power out of 25 horse-power. The working has always been effected without accident. In the same establishment there has also been employed, since the year 1879, two Gramme dynamos, one as a generator, the other as receiver for the testing of metals by means of a traction machine.

SHIP LIGHTING BY INCANDESCENCE.—The "Prince Albert" (1,062 tons B.M.), launched by the Cockerill Company at Antwerp on Wednesday week, is the first of a series of steel packets, built for the Belgian Government, for the mail service between Dover and Ostend, to have a stipulated speed of at least 17½ knots at sea. The vessel is to be lighted throughout by 90 incandescent lamps of varying intensity (16, 20, 30, and 50 candles); and also to be provided with two mast lights for lighting up the deck while passengers are going on board or on shore, to be extinguished the moment the steamer leaves her moorings. Each of these lights will consist of eight 50-candle incandescent lamps.

THE ELECTRIC LIGHT IN SHIPBUILDING.—A very happy and novel application of the electric light has been successfully effected in the shipbuilding yards of Lorient. Hitherto the interior of vessels during their construction has been in a state of almost complete darkness, the *employés* having to ply their various crafts by means of candlelight, a condition of things which left much to be desired in point of illumination. At the request of the engineers of naval constructions, MM. Sautter, Lemonnier, and Co. have just executed an installation of electric incandescent lamps, which can be moved about from place to place at will, just as candles, but of course being of infinitely greater illuminating power. The experiment has given the greatest satisfaction to the workmen.

THE CONVENTION OF ROYAL BURGHS AND THE TELEPHONIC SYSTEM.—At the recent annual meeting of the Convention of Royal and Parliamentary Burghs it was resolved to urge Government to acquire by purchase the telephonic system, and to work the same as a branch of the postal service. Mr. Officer, S.S.C., agent of the Convention, received on Monday a letter from the Postmaster-General acknowledging receipt of the communication, and saying:—"Lord Wolverton cannot but attach great weight to a recommendation coming from such a body as the Convention, and I am to say that the matter, which involves questions of importance and difficulty, shall receive his very attentive consideration.—I am, sir, your obedient servant, S. A. Blackwood."

THE SUEZ CANAL.—In the report which M. de Lesseps read before the shareholders of the Suez Canal Company in Paris on Tuesday it was stated that during the last two years the company has been making experiments with the electric light, with a view to enable vessels to continue their course through the canal by night. Those experiments having led to most favourable results, the company issued a notice on 3rd November authorising ships of war and postal steamers to continue their course during the night by the aid of the electric light in that portion of the canal comprised between Port Said and Kilomètre 54. Several of the Peninsular and Oriental Company's steamers have already availed themselves of that authorisation, and their navigation in the canal by night has proved a complete success.

WESTERN UNION.—The following remarks are made by the correspondent of the *Standard* upon the report just issued:—The omission of a declaration of a quarterly dividend has caused no surprise. The official report accompanying the announcement attributes the decrease in the revenue compared with the estimate to the payment of disputed taxes to the amount of one hundred and ninety-three thousand nine hundred and thirty-three dollars, which the company says the New York authorities must refund. The general business is declared to be unusually good, but it is off-set by the decreased revenues from the cables from the news service. The entire surplus, together with the last scrip dividend, has gone into plant, which can be distributed as stock or bonds, whichever is thought most expedient.

GOVERNMENT MONOPOLY OF THE TELEPHONE IN SPAIN.—The advisability of continuing the telephone system in Spain under Government control is reported to be under the consideration of the Minister of the Interior. About two years ago Señor Robledo, who was then Minister of the Interior, on

Digitized by Google

the pretext that it would be dangerous to allow the telephone service to be in the hands of a private company, monopolised it for the State. Two years of an expensive service for the public has resulted in a proposal to abandon the system; but, according to *El Dia*, the proposal is to grant a concession to a private individual, which, it is argued, would not result in any increased advantage to the public. It is urged that the telephonic service should be thrown open to the public free of privileges of any description. The contention with the gas company of Madrid (to which we refer in another column) is alluded to as an example of the evil effects of monopolies.

EXHIBITION IN PARIS.—We are informed that an international exhibition has been organised by the *Société National des Sciences and Arts Industriels* to be held in the Palais de l'Industrie. The exhibition will open on the 24th of July, remaining open till November. In the circular relating to the same it is said that since the exhibition of 1881—of which the results were very important regarding the industries connected with the general appliances of electricity, and particularly of the electric light—considerable progress has been made. The proposed exhibition, although it may not be so important as that of 1881, is expected to contain a very large number of interesting exhibits. The electric lighting department is under the direction of M. H. Fontaine. The promoters of this exhibition have thought that this year forms a medium period between the exhibition of 1881 and the proposed universal exhibition in 1889, and they hope the exhibits will show the progress that has been made during the last few years.

THE LIGHTING OF MADRID.—*El Dia* states that a second meeting was held in the Madrid Mercantile Club on Friday night last of the committee and representatives of the trading community appointed to arrange for the lighting of the city. It was stated that Messrs. Edison would not be able to complete the installation of the electric light before the month of October next. It was nevertheless decided to adhere to the original decision to completely abstain from the use of gas for lighting purposes as from the 1st July next, and to make arrangements in the meanwhile to substitute some other mode of lighting pending the installation of the electric light. The light recommended by the committee to be thus used temporarily is a gasoline light on the Wilhelm system. In reply to a question it was stated that the decision referred to does not preclude the use of gas as a motive power. The unanimity exhibited on this question appears to be due to the belief that in fighting the Gas Company a blow is being struck at the system of monopolies which are said to weigh heavily on the trade of the city.

ELECTRIC LIGHT IN PARIS.—The lighting of the Parisian theatres by means of electricity, which has been under consideration for a considerable time, is now about to be practically carried out. La Société Electro-Mecanique has undertaken to establish in the quarter of the Porte-Saint-Martin a central station, to provide the light to the numerous places of amusement in that busy part of the French capital, notably the theatres de la Renaissance, de la Porte-Saint-Martin, de l'Ambigu, des Folies-Dramatiques, du Château-d'Eau, de la Gaîté, des Menus-Plaisirs, du Gymnase, not to mention the concert rooms de l'Alcazar, de la Scala, Parisien, &c. The installation will doubtless be extended to the theatres des Variétés, and to some of the numerous restaurants and cafés which abound in the neighbourhood. Experiments will also shortly be made at the Théâtre Français, where the temperature has been hitherto rendered well nigh insupportable in consequence of the heat generated by the numerous gas lights, with the object of substituting the electric light for the rival illuminant.

EDINBURGH EXHIBITION. — Messrs. Andrews and Co. are lighting the machinery in motion section and the Old Edinburgh-street of the Exhibition with 33 Andrews arc lamps, which are connected in parallel circuits to two pairs of mains, one carrying 16 lamps, and the other 17. Each section of lamps is connected to a separate Andrews dynamo, but the main wires are arranged so that the whole of the lamps can be run from one of the machines. Throughout the department the neighbouring lamps are on alternate circuits, and are arranged to produce the best illumination of the exhibits; each light having a current of 25 amperes there is an abundance of light. The Old Edinburgh-street is lighted with one powerful lamp suspended from a pole above the buildings, which casts a moonlight effect into the street. The machines working these lamps are Andrews' well-known slow-speed dynamos, one a large machine, weighing 3½ tons, and capable of maintaining nearly double the whole number of lamps, running at a speed of 290 revolutions per minute, and the other a 35 unit machine, running at 400 revolutions per minute.

BURMAH.—In addition to our note of May 21, the following further information about the telegraph department in Burmah has recently been published:—"There has been some delay in the progress of telegraphic communication in consequence of the unsettled state of the country at present. The lines and offices have been made a special division in charge of a superintendent, who has under him four assistants and four sub-assistants, besides a large staff of trained signallers. All the labour in the way of coolies, some 200 or 300, is taken from Rangoon, and the work proceeds as rapidly as possible, seeing that escorts cannot always be obtained, and that the work is not allowed in many parts to be carried on without a military escort. Arrangements have been made for a line to Bhamo as soon as this protection can be afforded; another, between Mingyan and Yemethen, has been stopped because this is not forthcoming. It is proposed to connect Rangoon and Mandala by two lines, one running up by the river, and the other *via* Ningyan and Tounghoo. A line between Hymgyan and Yemethen will shortly be undertaken, as there is already a second line between Mandalay and Myingyan, and this will form part of the alternative line from Mandalay to Rangoon."

THE BELL TELEPHONE PATENTS.—It is now more than ten years, says the *Electrical World*, since a patent was granted to Alexander Graham Bell that has given rise to more controversies in the courts and the press than any other patent ever issued. The documents, arguments, and evidence in the various suits, and the books and pamphlets on the subject, would constitute a good-sized library. It is needless to enter into all the details of the points raised by the suit. They may be summarised as follows:—1. That Bell is not the original inventor of the speaking telephone, being anticipated by Reis, Dolbear, Gray, Meucci, Hughes, Varley, Edison, Boursel, and others. 2. That the patent No. 174,465 was obtained from the Patent Office by fraud. 3. That the same patent does not describe an operative instrument for transmitting speech, and hence is void. Fig. 7 is alleged to show an instrument that will not talk. 4. That undulatory current such as is described in the fifth claim of the same patent is not necessary to the transmission of articulate speech; and that if it be essential thereto, it constitutes a *principle*, which cannot be patented. 5. That the magneto-telephone now used as a receiver by the American Bell Company is Dolbear's, and that patent No. 186,787 is therefore invalid, said invention being communicated to Bell by a friend of Dolbear, and the latter being then

Digitized by Google

misled as to the fact of his own priority. These and other points will be brought out prominently at the trial of the suit. The Bell Company is understood to be of opinion that it has met one and all of them successfully in the many suits through which it has already passed without a single defeat.

THERMO-ELECTRICITY.—MM. Pilleur and E. Jannetaz, according to the *Journal de Physique*, have endeavoured to ascertain if, when a given point of a conductor is heated having a schistous texture, thermo-electric currents are produced in it. Then experiments extended to zinc, tin, iron, and copper. The schistous or long-grain texture was imparted to them by carefully drawing out. A point, A, at the centre of the plate is heated and one contact is made on the other side of the plate, at the end of the line which connects this point with A *across the long grain*, the other taken at a point, C, on the end of the line joining the point A *along the long grain*. In all cases a current was obtained from B to C. The strength of the current for the same metal appeared connected with the development of the *long grain*. Thus, that zinc which had passed four times through the draw-plate gave a feebler current than zinc which had been drawn out six times. But copper with a good deal of long grain, that is much more fragile in one direction than another, gave a feebler current than tin, which seemed to have no appreciable grain. It must, moreover, be observed that this tin had passed six times through the plate; hence the thermo-electric action shows the action of the draw-plate, even when the fracture does not show it. The strongest currents were shown by zinc, and the feeblest by copper. The currents are, however, difficult to observe, doubtless owing to the facility with which they unite across the plates themselves. More powerful effects may be obtained by cutting a knee-piece in the metal-plate, in one branch of which the long grain is across and in the other in the direction of the length, and then joining the two ends of the knee-piece to the external circuit.

THE ELECTRIC LIGHT IN MINES.—The coal pit St. Theodore of what is known as the coalfield Sacré-Madame (Belgium) has for the past two years been lighted by electricity. The installation comprises two arc lamps of 2,000 candle-power in the sorting shed and yard, and thirty Swan incandescent lamps of 20 candle-power in the various buildings. The motive power is supplied to the Gramme dynamos by a small engine of the Robey type, furnished with a regulator with centrifugal action. Since the 25th of January, 1884, the date when the installation was put in operation, up to the 15th of January, 1885, the expenses of every kind in connection with it (salaries, coal, oil, lamps, pencils, repairs of machines, &c.) have amounted to 1,859f., whilst for thirty gas burners, taking their average cost at other pits, the outlay has been 6,544f. The economy effected by substituting electricity for gas is therefore very appreciable. Moreover, thanks to the greater illuminating power of the electric light, coal can be, under these altered conditions, sorted and purified at night as well as during the daytime. Another advantage is that the workmen are enabled to pursue their avocations as many hours throughout the winter as they are throughout the summer months. The average duration of the incandescent lamps is 587 hours per lamp. Out of the thirty lamps first installed there remain nine in use, of which three lasted to the 25th of January, 1885, thus reaching the remarkable figure of 3,451 hours. The mean duration of these 30 lamps up to that date was therefore 760 hours. These results are exceedingly satisfactory, and augur well for the future application of electric lighting to this important industry. The *Mouvement Industrial Belge*, from which we extract the preceding details, says that as the result of this emphatic proof of the advantages of the electric light, the directorate of this large coalfield have decided to illuminate the whole of the pits with the electric light.

PROGRESS OF INDUSTRIAL ELECTRICITY.—"How was that made?" This question was asked of a prominent metal merchant as a vessel was handed him, made in the shape of a head-light reflector. It was composed of copper about one sixty-fourth inch thick, tough, pliable, and very smooth on the inner surface. Examining the edges of the flange, the merchant noticed that the thickness of the metal did not vary in the least around the entire rim. "It was spun?"—"No." "Stamped?"—"No." "Pressed?"—"No." "Cast? Impossible!"—"No, it was not cast." "Then it must have grown." It had grown, but it was with the rapidity that only electricity can give to growth. The process by which the above casting or vessel was made is as follows:—A rigid male form is made of the approximate shape and less in size than the article wished to be reproduced. This form is then immersed in a kettle of refined wax, paraffin, or similar substance. The shape of form will decide in what position the form is to be held; in the case of a reflector the form is held with small end up. The way must be pure and free from dirt or water to get best results. The wax is heated so that it will run nicely. By immersing form in kettle and withdrawing vertically, the wax will run smoothly, and as it cools in a few seconds leaves a smooth, true surface. This surface is now rendered conductive with the well-known electrotyper's process, by the application of black lead, iron filings, and blue vitriol. The whole thing is then immersed in a copper solution, and connected electrically with a dynamo. Copper anodes are also put in solution, and connected electrically with opposite pole of dynamo. The dynamo is set in motion, and the "growth" of a vessel begins. The thickness of vessel is dependent upon the length of time deposit is allowed to continue; pieces of copper an inch thick have been made. The time required to make a vessel of a certain weight and size depends altogether upon the size of the dynamo. The perfection and strength attained by these "electric engines" through the perseverance of recent inventors and manufacturers is something marvellous.—*Electrical World.*

SHIP LIGHTING.—The electric light has for some time asserted its supremacy over all competitors in the immense passenger steamers turned out from the Clyde, and it is now beginning to obtain a strong foothold on much smaller vessels. The "Alejandro," a small yacht-built steamer of about a thousand tons, just finished by the Sunderland Shipbuilding Company, and intended for the Mexican passenger coasting trade, has been fitted throughout with the electric light, to the total exclusion of oil. The number of 18 candle-power incandescent lamps is seventy-five, two deck clusters of twelve lamps each being supplied for use when discharging cargo. The whole of the work was carried out by Messrs. Dorman and Smith, of Manchester. The same firm has also been entrusted with the contract for lighting the "Euterpe," a fine passenger steamer now building for the Austro-Hungarian Lloyd's by Messrs. J. L. Thompson and Sons, of Sunderland.—Messrs. Andrews and Co. have just completed an installation of about 100 lights on board the ss. "Dynamic," which has been under alteration by Messrs. Workman Clark and Co., of Belfast. The current is supplied by one of Andrews' patent dynamos, running at a speed of 500 revolutions per minute. The light has been distributed throughout every portion of the ship with the exception of the signal lamps. Two clusters (portable) of three 50 candle-

Digitized by Google

power lamps each are used to light the hatches when loading or discharging cargo. The fittings throughout have been manufactured by Messrs. Andrews and Co., and are of a thoroughly substantial character and admirably suited to their various positions. The light in the saloon is especially brilliant, and the handsome nickled fittings give it a very effective appearance. One particular which is worthy of note is the despatch with which the electrical outfit has been completed, the vessel having only been laid up for a fortnight, and the trial of the electric light having been made, with the most satisfactory results, the night before she left the dock. Besides this work Messrs. Andrews and Co. have just completed the electric lighting of the second of three Atlantic steamers for the North German Lloyd's.

THE "COLOSSUS."—Last Saturday, in response to an invitation from Lord Charles Beresford, about 150 members of Parliament and a number of other distinguished visitors left London for Portsmouth in order to witness a modern naval sham fight. One of the most interesting of the vessels engaged in this fight was the "Colossus," of which the following interesting note is given by the *Daily Telegraph* correspondent :— "The 'Colossus' is really more a mighty floating steel battery than a ship. She is a steel-armoured vessel of over 9,000 tons burthen, with double turrets and twin screws. She is short and broad, being about 350ft. long and 68ft. beam. She is furnished with electrical apparatus for incandescent lamps to light the ship, and for arc lights to guard against attacks by torpedo boats. Her armament consists of four 43-ton guns, similar to the pattern now considered unsafe, five six-inch breechloading cannon, and a number of quick-firing Hotchkiss, Nordenfelt, Gardner, and other guns, and torpedoes. The hydraulic machinery working the turret and the 43 ton guns was shown in motion. The 43 ton guns are ranged side by side like big reversed binocular glasses. Shotted and fired together, as they can be, each hurling its 714lbs. of shot with a punching power than can pierce over 20in. of solid iron at 1,000 yards, they would deliver an awful double-handed blow at an enemy. Below deck the 'Colossus' has passage ways as tortuous, narrow, and bewildering as Egyptian catacombs. Were the electric light to fail and none other available, it would be well-nigh impossible to find one's way back to daylight. The engine room had a tropical heat, and it was said that the stokehole, when in full blast, must be a veritable oven. In the electrical machinery room the thermometer on Saturday stood at 116 deg. Fahr., and the workmen were as lightly clad and as warm apparently as sugar-house *employés*. That electrical room has been a boon to Portsmouth watchmakers, for every watch taken therein is lost. Not actually filched out of the pocket, but quite as bad. Electricity lays hold of the steel parts of the watch in less time than it takes to write about it, makes magnets of them, and for ever thereafter the hours come and go upon the dial in the most eccentric and unreliable way. The officers and crew of the 'Colossus' have ruined scores of watches by wearing them in that room. Subsequently tea was served in the officers' quarters to the visitors. After a most agreeable hour the party returned to the tugs and steamed back to Portsmouth, when the 'special' train conveyed them to London, which was reached about 7:30 p.m. There was but one opinion expressed, and that was that the day had been extremely pleasantly and profitably spent. The trip brought out in a large degree what the might and responsibility of Empire in some measure mean, and the general wish was expressed that others, and especially our colonial brethren and visitors, should participate occasionally in such visits to one or other of the great Government establishments."

TELEPHONY.—M. Rothen continues in the last number of the *Journal Télégraphique* the statistics relating to telephony. M. Rothen's previous communication will be found p. 509 of our issue of May 7 last :—

In the United States the number of exchanges is 752, of stations 151,056, of *employés* 5,700, and the length of the wires is 138,207 kilometres. A capital of 500 million francs is employed. In 1884 the gross receipts amounted to 47,500,000fr., and the expenses to 30,250,000fr. Our statistics are somewhat incomplete, and relate to some of the most important exchanges. At Buffalo each "conversation" costs from 20 to 30 centimes (according to the number of "conversations" held) annually—a principle appreciated by the public. The exchange of Philadelphia is in communication with 42 other central offices.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XXVII.

BY OLIVER HEAVISIDE.

(Continued from page 9.)

The Variable Period in a Round Wire with a Concentric Tube at any Distance for the Return Current.

The case considered in the last section was an extreme one of departure from the linear theory. This arose, not from mere size, but from the closeness of the return to the main conductor, and to its completely enclosing it. Practically we must separate the two conductors by a thickness of dielectric. The departure from the linear theory is then less pronounced; and when we widely separate the conductors it tends to be confined to a small portion only of the variable period. The size of the wire is also then of importance.

Let there be a straight round wire of radius a_1, conductivity k_1, and inductivity μ_1, surrounded by a non-conducting dielectric of specific capacity c and inductivity μ_2 to radius a_2, beyond which is a tube of conductivity k_3, and inductivity μ_3, inner radius a_2 and outer a_3. The object of taking c into account, temporarily, will appear later.

Let the current be longitudinal and the magnetic force circular. Then, by (1*b*), if γ is the current density at distance r from the axis, we shall have

$$\frac{1}{r}\frac{d}{dr}\,r\,\frac{d\gamma}{dr}=4\pi\mu k\dot{\gamma},\qquad \text{or}=c\mu\ddot{\gamma},\quad .\ .\ .\quad (18b)$$

in the conductors, and in the dielectric respectively; the latter form being got by taking $\gamma=c\dot{\mathrm{E}}/4\pi$, the rate of increase of the elastic displacement.

A normal system of longitudinal current density may therefore be represented by

$$\left.\begin{aligned}\gamma_1&=\mathrm{A}_1\mathrm{J}_0(n_1r), && \text{from } r=0 \text{ to } a_1\\ \gamma_2&=\mathrm{A}_2\mathrm{J}_0(n_2r)+\mathrm{B}_2\mathrm{K}_0(n_2r), && \text{,, ,, } a_1\text{,, } a_2\\ \gamma_3&=\mathrm{A}_3\mathrm{J}_0(n_3r)+\mathrm{B}_3\mathrm{K}_0(n_3r), && \text{,, ,, } a_2\text{,, } a_3\end{aligned}\right\}.\quad (19b)$$

in the wire, in the insulator, and in the sheath, respectively, at a given moment. In subsiding, free from impressed force, each of these expressions, when multiplied by the time factor ϵ^{pt}, gives the state at the time t later.

$\mathrm{J}_0(nr)$ is the Fourier cylinder function, and $\mathrm{K}_0(nr)$ the complementary function. (For their expansions see *The Electrician*, Aug. 23, 1884, p. 328, equations (70) and (71)). The A's and B's are constants, fixing the size of the normal functions; the n's are constants showing the nature of the distributions, and p determines the rapidity of the subsidence.

By applying (18*b*) to (19*b*) we find

$$n_1^2=-4\pi\mu_1k_1p,\quad n_2^2=-\mu_2cp^2,\quad n_3^2=-4\pi\mu_3k_3p\,;\ .\quad (20b)$$

expressing all the n's in terms of the p.

Corresponding to the expressions (19*b*) for the current, we have the following for the magnetic force:—

$$\left.\begin{aligned}\mathrm{H}_1&=-(n_1/\mu_1k_1p)\mathrm{A}_1\mathrm{J}_1(n_1r),\\ \mathrm{H}_2&=-(4\pi n_2/\mu_2cp^2)\{\mathrm{A}_2\mathrm{J}_1(n_2r)+\mathrm{B}_2\mathrm{K}_1(n_2r)\},\\ \mathrm{H}_3&=-(n_3/\mu_3k_3p)\ \{\mathrm{A}_3\mathrm{J}_1(n_3r)+\mathrm{B}_3\mathrm{K}_1(n_3r)\},\end{aligned}\right\}.\quad (21b)$$

where, as is usual, the negative of the differential coefficient of $\mathrm{J}_0(z)$ with respect to z is denoted by $\mathrm{J}_1(z)$; and, in addition, the negative of the differential coefficient of $\mathrm{K}_0(z)$ with respect to z is denoted by $\mathrm{K}_1(z)$. These equations (21*b*) are got by the second and third equations (1*b*), in the case of H_1 and H_3; and in case of H_2, by using, instead of Ohm's law, the dielectric equation, giving

$$\mathrm{E}=4\pi\gamma/cp,$$

in the dielectric, E being the electric force. Of course $d/dt=p$, in a normal system.

We have next to find the relations between the five A's and B's, to make the three solutions fit one another, or harmonise. This we must do by means of the boundary conditions. These are nothing more than the surface interpretations of the ordinary equations referring to space distributions. In the present case the appropriate conditions are continuity of the magnetic and of the electric force at the boundaries, because the two forces are tangential; the conditions of continuity of the normal components of the electric current and of magnetic induction are not applicable, because there are no normal components in question. If the magnetic or the electric force were discontinuous, we should have electric or magnetic current sheets.

Thus H_1 and H_2 are equal at $r=a_1$, and H_2 and H_3 are equal at $r=a_2$. These give, by (21*b*),

$$(\mathrm{A}_1n_1/\mu_1k_1p)\mathrm{J}_1(n_1a_1)=(4\pi n_2/\mu_2cp^2)\{\mathrm{A}_2\mathrm{J}_1(n_2a_1)+\mathrm{B}_2\mathrm{K}_1(n_2a_1)\},\quad (22b)$$

and

$$\begin{aligned}&(4\pi n_2/\mu_2cp^2)\{\mathrm{A}_2\mathrm{J}_1(n_2a_2)+\mathrm{B}_2\mathrm{K}_1(n_2a_2)\}\\ &\quad=(n_3/\mu_3k_3p)\{\mathrm{A}_3\mathrm{J}_1(n_3a_2)+\mathrm{B}_3\mathrm{K}_1(n_3a_2)\}.\quad .\quad (23b)\end{aligned}$$

Similarly, E_1 and E_2 are equal at $r=a_1$, and E_2 and E_3 are equal at $r=a_2$. These give, by (19*b*),

$$(\mathrm{A}_1/k_1)\mathrm{J}_0(n_1a_1)=(4\pi/cp)\{\mathrm{A}_2\mathrm{J}_0(n_2a_1)+\mathrm{B}_2\mathrm{K}_0(n_2a_1)\}\ .\quad (24b)$$

and

$$\begin{aligned}&(4\pi/cp)\{\mathrm{A}_2\mathrm{J}_0(n_2a_2)+\mathrm{B}_2\mathrm{K}_0(n_2a_2)\}\\ &\quad=k_3^{-1}\{\mathrm{A}_3\mathrm{J}_0(n_3a_2)+\mathrm{B}_3\mathrm{K}_0(n_3a_2)\}\quad .\quad .\quad (25b)\end{aligned}$$

Thus, starting with A_1 given, (22*b*) and (24*b*) give A_2 and B_2 in terms of A_1, and then (23*b*) and (25*b*) give A_3 and B_3 in terms of A_1. Similarly we might carry the system further, by putting more concentric tubes of conductors and dielectrics, or both, outside the first tube, using similar expressions for the magnetic and electric forces; every fresh boundary giving us two boundary conditions of continuity to connect the solution in one tube with that in the next. But at present we may stop at the first tube. Ignore the dielectric displacement beyond it, *i.e.*, put $c=0$ beyond $r=a_3$, because our tube is to be the return conductor to the wire inside it. We may merely remark in passing that although when such is the case, there is, in the steady state, absolutely no magnetic force without the tube, yet this is not exactly true in a transient state. To make it true, take $c=0$ beyond $r=a_3$; requiring $\mathrm{H}_3=0$ at $r=a_3$. This gives, by (21*b*),

$$\mathrm{A}_3\mathrm{J}_1(n_3a_3)+\mathrm{B}_3\mathrm{K}_1(n_3a_3)=0\quad .\quad .\quad .\quad (26b).$$

Now A_3 and B_3 are, by the previous, known in terms of A_1. Make the substitution, and we find, first, that A_1 is arbitrary, so that it, when given, fixes the size of the whole normal system of electric and magnetic force, and next, that the n's are subject to the following equation,

$$\begin{aligned}&\frac{\dfrac{n_3}{\mu_3}\mathrm{J}_0(n_2a_2)\dfrac{\mathrm{J}_1(n_3a_2)\mathrm{K}_1(n_3a_3)-\mathrm{J}_1(n_3a_3)\mathrm{K}_1(n_3a_2)}{\mathrm{J}_0(n_3a_2)\mathrm{K}_1(n_3a_3)-\mathrm{J}_1(n_3a_3)\mathrm{K}_0(n_3a_2)}-\dfrac{n_2}{\mu_2}\mathrm{J}_1(n_2a_2)}{\dfrac{n_3}{\mu_3}\mathrm{K}_0(n_2a_2)\times\ .\ .\ .\ .\ .\ .\ .\ .\ .\ .-\dfrac{n_2}{\mu_2}\mathrm{K}_1(n_2a_2)}\\ &\quad=\frac{(n_1/\mu_1)\mathrm{J}_1(n_1a_1)\mathrm{J}_0(n_2a_1)-(n_2/\mu_2)\mathrm{J}_1(n_2a_1)\mathrm{J}_0(n_1a_1)}{(n_1/\mu_1)\mathrm{J}_1(n_1a_1)\mathrm{K}_0(n_2a_1)-(n_2/\mu_2)\mathrm{K}_1(n_2a_1)\mathrm{J}_0(n_1a_1)}\quad .\ .\quad (27b)\end{aligned}$$

where, on the left side, to save trouble, the dots represent the same fraction that appears in the numerator immediately over them.

Now, the n's are known in terms of p, hence (27*b*) is the determinantal equation of the p's, determining the rates of subsidence of all the possible normal systems. We have, therefore, all the information required in order to solve the problem of finding how any initially given state of circular magnetic force and longitudinal electric force in the wire, insulator, and sheath subsides when left to itself. We merely require to decompose the initial states into normal systems of the above types, and then multiply each term by its proper time factor ϵ^{pt} to let it subside at its proper rate. To effect the decomposition, make use of the universal conjugate property of the equality of the mutual potential and the mutual kinetic energy of two complete normal systems, $\mathrm{U}_{12}=\mathrm{T}_{12}$ (*Electrician*, Nov. 27, 1885, p. 46), which results from the equation of activity. We start with a given amount of electric energy in the dielectric, and of magnetic energy in the wire, dielectric and sheath, which are finally used up in heating the wire and sheath, according to Joule's law.

It would be useless to write out the expressions, for I have no intention of discussing them in the above general form, especially as regards the influence of c. Knowing from experience in other similar cases that I have examined, that the effect of the dielectric displacement on the wire and sheath phenomena is very minute, we may put $c=0$ at once between the wire and

Digitized by Google

the sheath. We might have done this at the beginning ; but it happens that although the results are more complex, yet the reasoning is simpler, by taking c into account.

The question may be asked, how set up a state of purely longitudinal electric force in the tube, sheath, and intermediate dielectric? As regards the wire and sheath, it is simple enough ; a steady impressed force in any part of the circuit will do it (acting equally over a complete section). But it is not so easy as regards the dielectric. It requires the impressed force to be so distributed in the conductors as to support the current on the spot without causing difference of potential. There will then be no dielectric displacement either (unless there be impressed force in the dielectric to cause it). Now, if we remove the impressed force in the conductors, the subsequent electric force will be purely longitudinal in the dielectric as well as in the conductors.

But practically we do not set up currents in this way, but by means of localised impressed forces. Then, although the steady state is one of longitudinal electric force in the wire and sheath, in the dielectric there is normal or outward electric force as well as tangential or longitudinal, and the normal component is, in general, far greater than the tangential. In fact, the electrostatic retardation depends upon the normal displacement. But electrostatic retardation, which is of such immense importance on long lines, is quite insignificant in comparison with electro-magnetic on short lines, and in ordinary laboratory experiments with closed circuits (no condensers allowed) is usually quite insensible. We see, therefore, that when we put $c=0$, and have purely longitudinal electric force, we get the proper solutions suitable for such cases where the influence of electrostatic charge is negligible, irrespective of the distribution of the original impressed force. Our use of the longitudinal displacement in the dielectric, then, was merely to establish a connection in time between the wire and the sheath, and to simplify the conditions. In passing, I may give a little bit of another investigation. Take both electrostatic and electro-magnetic induction into consideration in this wire and sheath problem, treating them as solids in which the current distribution varies with the time. The magnetic force is circular, so is fully specified by its intensity, say H, at distance r from the axis. Its equation is, if z be measured along the axis,

$$\frac{d}{dr}\frac{1}{r}\frac{d}{dr}rH+\frac{d^2H}{dz^2}=4\pi\mu k\dot{H}+\mu c\dot{H},$$

in which discard the last term when the wire or sheath is in question; or retain it and discard the previous when the dielectric is considered. The form of the normal H solution is

$$H=J_1(sr)(A\sin+B\cos)mz.\epsilon^{pt},$$

for the wire, where $s^2=-(4\pi\mu kp+m^2)$. The current has a longitudinal and a radial component, say Γ and γ, given by

$$\Gamma=sJ_0(sr)(A\sin+B\cos)mz.\epsilon^{pt},$$
$$\gamma=-mJ_1(sr)(A\cos-B\sin)mz.\epsilon^{pt}.$$

In the dielectric and sheath the K_0 and K_1 functions have, of course, to be counted with the J_0 and J_1.]

Now put $c=0$ in (27b). We shall have

$J_0(n_2r)=1$; $-n_2J_1(n_2r)=0$; $K_0(n_2r)=\log(n_2r)$; $-n_2rK_1(n_2r)=1$;

which will bring (27b) down to

$$\frac{n_3}{\mu_3}\cdot\frac{J_1(n_3a_2)K_1(n_3a_3)-J_1(n_3a_3)K_1(n_3a_2)}{J_0(n_3a_2)K_1(n_3a_3)-J_1(n_3a_3)K_0(n_3a_2)}$$
$$\times\{(\mu_1a_2/n_1a_1)J_0(n_1a_1)-\mu_2a_2J_1(n_1a_1)\log(a_2/a_1)\}=J_1(n_1a_1),\quad(28b)$$

the determinental equation in the case of ignored dielectric displacement.

To obtain this directly, establish a rigid connection between the magnetic and electric forces at $r=a_1$ and at $r=a_2$, thus. Since there is no current in the insulating space, the magnetic force varies inversely as the distance from the axis of the wire. Therefore, instead of the second of (21b) we shall have

$$H_2=-(n_1/\mu_1k_1p)A_1J_1(n_1a_1)(a_1/r),$$

by the first of (21b). Thus H_2 at $r=a_2$ is known, and, equated to H_3 at $r=a_2$, gives us one equation between A_1, A_3, and B_3.

Next we have

$$\int_{a_1}^{r}(a_1/r)H_1dr=H_1a_1\log(r/a_1)=-(n_1a_1/\mu_1k_1p)J_1(n_1a_1)\log(r/a_1)$$

H_1 meaning, temporarily, the value of H_1 at $r=a_1$. This, when multiplied by μ_2, is the amount of induction through a rectangular portion of a plane through the axis, bounded by straight lines of unit length parallel to the axis at distances a_1 and r from it; or the line integral of the vector potential round the rectangle ; or the excess of the v.p. at distance r over that at distance a_1; so, when multiplied by p, it is the excess of the electric force at a_1 over that at r. Thus the electric force is known in the insulating space in terms of that at the boundary of the wire. Its value at $r=a_2$ equated to E_3 at $r=a_2$ gives us a second equation between A_1, A_3, and B_3. The third is equation (26b) over again, and the union of the three gives us (28b) again.

We now have, if γ_1 and γ_3 are the *actual* current densities at time t in the wire and the sheath respectively,

$$\left.\begin{aligned}\gamma_1&=\Sigma AJ_0(n_1r).\epsilon^{pt}\\ \gamma_2&=\Sigma B\{J_0(n_3r)-J_1(n_3a_3)K_0(n_3r)/K_1(n_3a_3)\}.\epsilon^{pt}\end{aligned}\right\}.\quad(29b),$$

where $$B=A\frac{k_3}{k_1}\frac{J_0(n_1a_1)-n_1a_1(\mu_2/\mu_1)J_1(n_1a_1)\log(a_2/a_1)}{J_0(n_3a_2)-J_1(n_3a_3)K_0(n_3a_2)/K_1(n_3a_3)}$$

in which only the A requires to be found, so that when $t=0$, the initial state may be expressed. The decomposition of the initial state into normal systems may be effected by the conjugate property of the vanishing of the mutual kinetic energy, or of the mutual dissipativity of a pair of normal systems. Thus, in the latter case, writing (29b) thus, $\gamma_1=\Sigma Au$, $\gamma_3=\Sigma Av$, we shall have

$$\int_0^{a_1}u_1u_2rdr/k_1+\int_{a_2}^{a_3}v_1v_2rdr/k_3=0,$$

u_1, v_1, and u_2, v_2 being a pair of normal solutions

We can only get rid of those disagreeable customers, the K_0 and K_1 functions, by taking the sheath so thin that it can be regarded as a linear conductor—*i.e.*, neglect variations of current density in it, and consider instead the integral current. (Except when the sheath and wire are in contact and of the same material, as in the last section.) Let a_4 be the very small thickness of the sheath, and evaluate (28b) on the supposition that a_4 is infinitely small, so that a_2 and a_3 are equal ultimately. The result is

$$J_0(n_1a_1)=a_1J_1(n_1a_1)\{(n_1\mu_2/\mu_1)\log(a_2/a_1)-k_1/n_1k_3a_2a_4\},\quad(30b)$$

the determinantal equation in the case of a round wire of radius a_1 with a return conductor in the form of a very thin concentric sheath, radius a_2. Notice that μ_3, the inductivity of the sheath itself, has gone out altogether ; that is, an iron sheath for the return, if it be thin enough, does not alter the retardation as compared with a copper sheath, provided the difference of conductivity be allowed for.

We may get (30b) directly, easily enough, by considering that the total sheath current must be the negative of the total wire current, which last is, by integrating the first of (29b) throughout the wire,

$$=(A/n_12\pi a_1\Sigma)J_1(n_1a_1).\epsilon^{pt}.$$

This, divided by the volume of the sheath per unit length, that is, by $2\pi a_2a_4$, gives us the sheath current density, and this, again, divided by k_3 gives us the electric force at $r=a_2$. Another expression for the electric force at the sheath is given by the previous method (the rectangle business). Equate them, and (30b) results.

We have now got the heavy work over, and some results of special cases will follow, in which we shall be materially assisted by the analogy of the eddy currents in long cores inserted in long solenoidal coils.

(To be continued.)

FORTHCOMING SALE OF SURPLUS PLANT.—On reference to our advertisement columns it will be seen that the sale by Messrs. Wheatley Kirk, Price, and Goulty of the Edison and Swan United Company's stock of surplus electrical plant has been postponed from June 23rd and 24th to Wednesday and Thursday, July 7th and 8th.

PRACTICAL ELECTRICITY FOR AMATEURS.—III.*

Electric Bells and Indicators.

At the latter part of our last article, Fig. 16 was without the reference letters referred to in the description; *a* is the upper contact against which the button spring is pressing, the *b* after the word bell is not required, *c* is the bottom contact against which the button spring comes when the button is pressed.

Indicators.—Where electric bells are fitted to several rooms it is necessary to use indicators, several being placed in one case. Fig. 17 shows a design much used on the Continent. It consists of a fixed electro-magnet, M, and permanent magnet, N S, to which is attached a pivoted arm, carrying a light, parti-coloured vane at the top. The connections are so made that when a push is acted upon, M attracts N and repels S, causing the vane to take the position shown, to reset the vane, a button placed in or near the indicator case is pressed, which sends a current in the reverse direction, causing M to repel N and attract S, thus throwing the vane over into its normal position.

In this country indicators which drop a shutter or disc are mostly used, but the pendulum indicators which swing for a considerable time and do not require resetting are much to be preferred. One form of this kind is shown by Fig. 18. The vane is preferably made of corrugated silvered glass, which can be seen in dark situations, where a coloured vane would be quite undistinguishable.

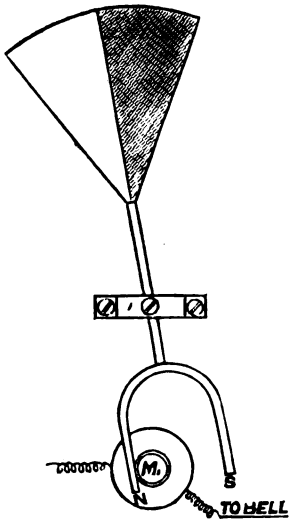

Fig. 17.

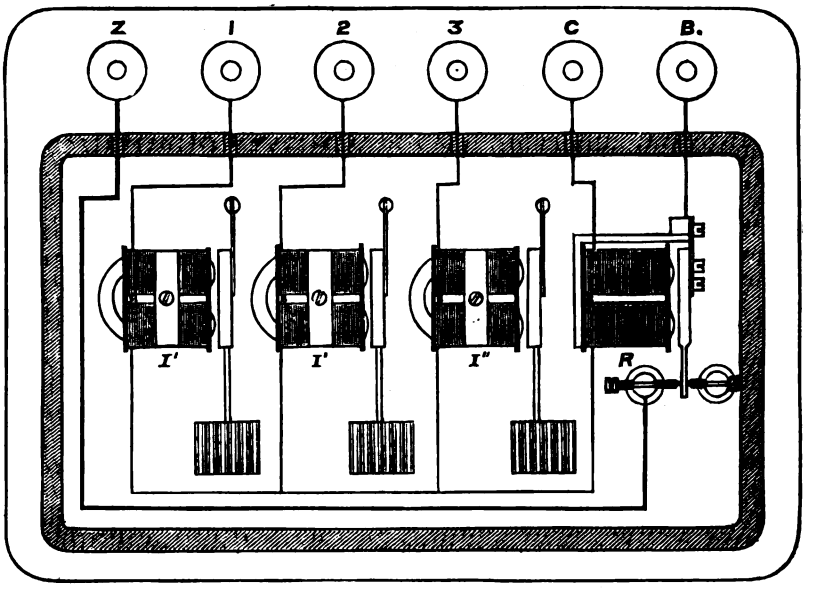

Fig. 19.

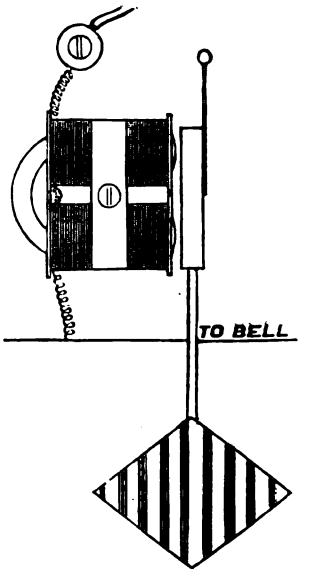

Fig. 18.

The grouping of the indicators in one case is shown by Fig. 19; the current enters by terminals 1, 2, or 3, as the case may be, traverses the coils of the particular electro-magnet connected therewith, reaching the coils of relay R by the wire common to all (causing the local bell circuits to be closed, thus ringing the bell), then to C, which is connected to carbon of battery.

The Battery.—The best battery for general electric bell work is undoubtedly the Leclanché, and preferably the *old form* of that kind; in very large hotels, however, the Fuller bichromate battery may be preferable.

Fire Alarms and Thief Detectors.

Fig. 20 shows a good form of door or window contact. The bolt is held back against the pressure of the spring, so that the circuit is broken, but when the door or window is opened the bolt comes forward into contact with the block, thus completing the circuit, and causing the bell to ring. These should be placed in door posts on the hinge side, and in window frames at top and bottom.

Fig. 21 shows a fire or frost alarm. It consists of a metal tongue of brass and steel, riveted together and fixed at one end, the other end being free to move between the stops A and B,

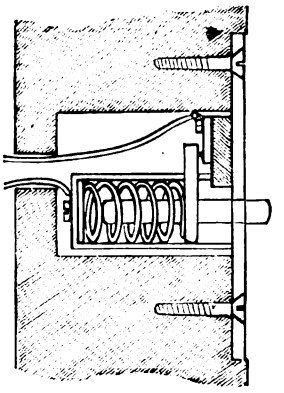

Fig. 20.

the action of heat moving the tongue towards the stop A, and the action of cold towards the stop B. This arrangement is very useful in greenhouses, &c., giving immediate notice of too great heat or cold by ringing a bell, or it can be made to act upon the ventilating and heating arrangements direct.

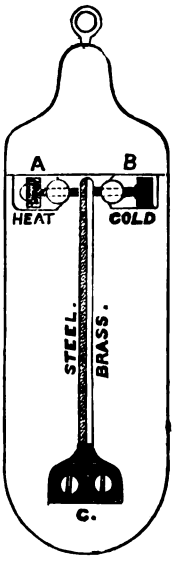

Fig. 21.

* For Article II. see *The Electrician* for May 21, 1886.

Digitized by Google

For purely fire alarm purposes, a modification of a differential thermometer is perhaps the best, as the alarm is only given when a sudden rise of temperature takes place, and not when a predetermined temperature is attained.

CONNECTING-UP BELLS, INDICATORS, AND BATTERIES.

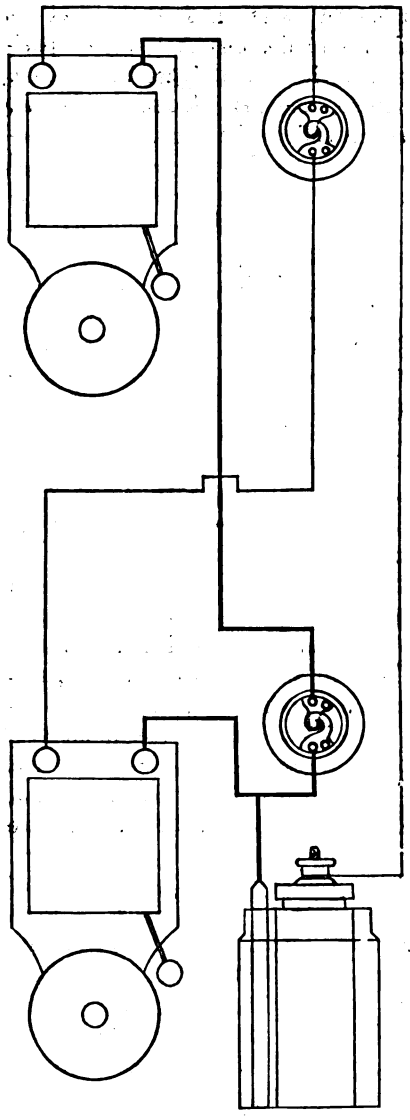

FIG. 23.

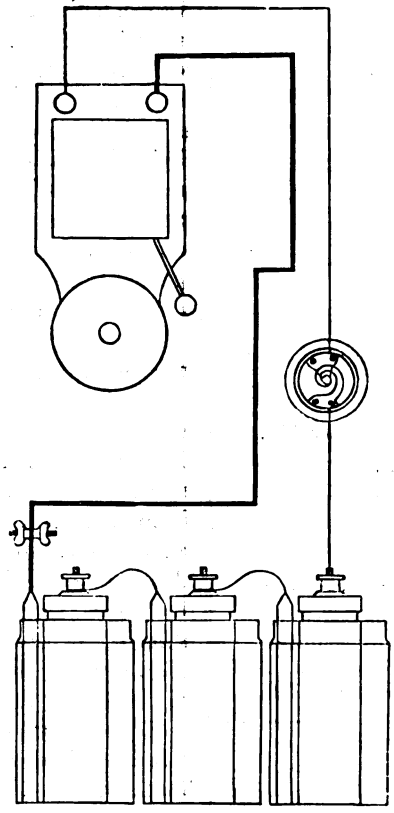

FIG. 22.

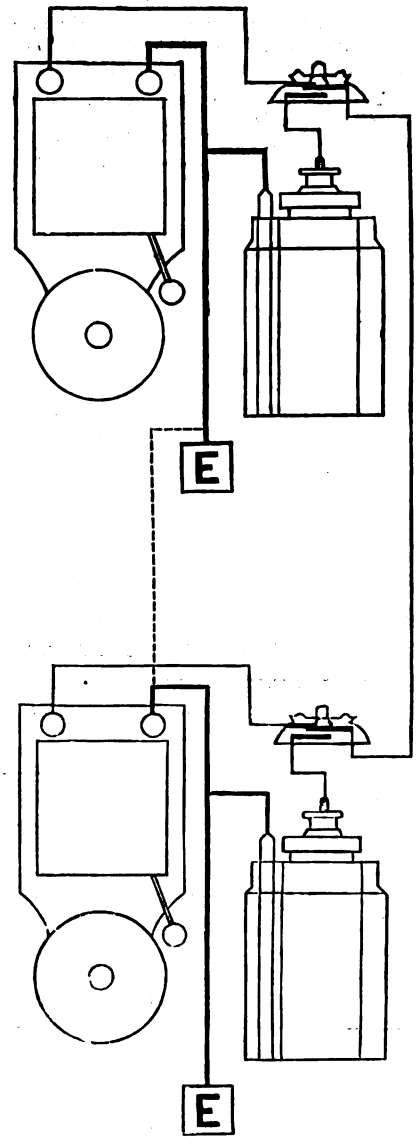

FIG. 24.

It is hoped the following diagrams are sufficiently distinct, so that very little description will be required. The Z or return wire is shown thicker than the C wire. Fig. 22 shows a simple bell circuit.

Fig. 23 shows an arrangement of electric bells to ring in both directions, using only one battery and ordinary pushes, but requires *three* wires, and is therefore only suitable for short distances.

Fig. 24 shows another arrangement to ring both ways, requiring "key pushes," previously described (Fig. 16, page 27), a battery at each end, one line wire, and earth connections (a water-pipe is sufficient), or a second line wire (as shown by the dotted line) may be used.

Fig. 25 shows method of connecting up continuous ringing bell, shown by Fig. 6, page 26.

Fig. 26 shows connections for continuous bell, shown by Fig. 7, page 26.

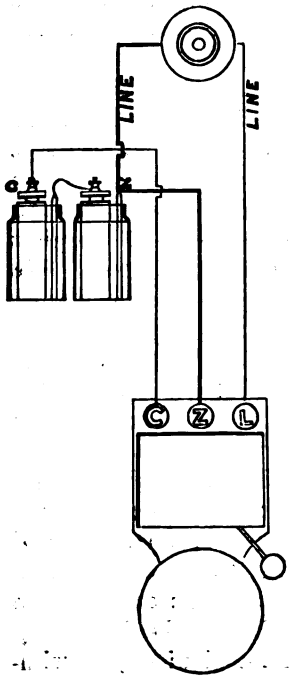

FIG. 25.

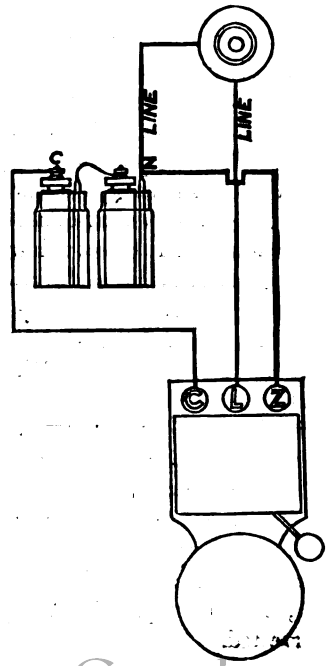

FIG. 26.

FIRING SHOTS IN MINES.—MM. Scola and Ruggieri have suggested a modification of the usual method of firing shots in mines. The ends of two cotton-covered copper wires are wound upon a small wooden cylinder. Around the wires is a cartridge filled with a mixture of chloride of potash, saltpetre, sulphide of antimony, and finely divided carbon; the latter is used to give feeble conductivity to the mass. The wires are connected with an induction coil, and a spark obtained at will to explode the mixture and powder or dynamite of the charge.

THE ELECTRIC LIGHTING ACT AMENDMENT BILL.

It will be seen by an announcement we make in another column that of the three measures for amending the ELECTRIC LIGHTING ACT of 1882, referred to a Select Committee of the House of Lords a few weeks ago, the one submitted by Lord HOUGHTON on the part of the Government has been adopted. It does not follow that this Bill as finally agreed upon by the Committee will become law, or that it is still incapable of being amended in a direction more favourable to Electric Lighting undertakers. Parliamentary committees of inquiry usually contain a preponderance of Government supporters; and as the present Ministry are pledged to resist the creation of any fresh vested interests, except under conditions which secure a reversionary interest to the local authorities, it is not surprising that the scheme of amendment put forward by Lord HOUGHTON has secured a majority of votes. The Bill, which we print in another column, shows, however, that its competitors have exerted some salutary influence on its provisions; and that, in fact, it is a compromise designed to reconcile all the parties interested.

There is undoubtedly much reason to be gratified with the general drift of these proceedings, even though we may not be entirely satisfied with the present result. In the first place it was a great triumph for the opponents of the Act of 1882 to have extorted an admission from a Government which enacted the abortive measure, that not only had it failed to do what it professed to do, but that it had positively undone all the work that it was designed to promote. A fresh start had to be made, and Lord HOUGHTON'S Bill, introduced on the 1st April, extended the term of the provisional order to 30 years, and, with the consent of the local authority, to a further term of 12 years. The principle of compulsory purchase, or confiscation as it may be more correctly designated, was maintained, but its period of grace was enlarged by at least one-third. A principle so elastic as this is obviously capable of expansion; a further concession of 20 or 30 years would be quite consistent with its essence; and except for the fact that the dominant political party just now is hostile to the leasehold system, a 99 years' lease might be granted to the undertakers without in the least violating the principle of compulsory reversion.

It will be remembered that the two Amendment Bills introduced respectively by Lord RAYLEIGH and Lord BURY were framed on different lines. Lord RAYLEIGH proposed to abolish Clause 27 absolutely, and to place Electric Lighting enterprise on identical, or almost identical, footing with Gas Lighting and other similar commercial undertakings. Viscount BURY, yielding more to the spirit of the age, was content to extend the operation of the provisional order from 21 to at least 42 years; but with this important difference, that instead of authorising a purchase on the basis of "old material," he insisted that the business should be valued and paid for as a "going concern." Lord HOUGHTON'S alternative on the part of the Government extended the minimum term to 30 years, but did not modify in any way the conditions of purchase laid down in the Act of 1882. He objected to Lord RAYLEIGH'S Bill because it would establish a new set of vested interests; which was quite true, though we do not see the force of the objection. And he objected still more to Lord BURY'S proposal because "it would create a more dangerous because more insidious form of monopoly;" which is by no means obvious, and even if it were, the Government proposal is open to a similar objection, unless, indeed, the difference between a dangerous monopoly and an innocent monopoly is that the one may not be deprived of its rights without compensation, whilst the other may.

It is absurd to use language like that ascribed to Lord HOUGHTON in reference to a purely business matter, one essential element of which is common honesty. Without that as a preliminary security there can be no business, as the Act of 1882 has sufficiently demonstrated. The real danger lies in creating uncertainty of tenure and certainty of risk, against which no healthy or legitimate business can contend. We should suspect the good faith of any undertaking which accepted the terms of Lord HOUGHTON'S original amendment Bill; and apparently he has been brought to see this himself. In the Bill as amended after the ordeal of a Select Committee, we find that he has consented to a further extension of the term of the provisional order to 42 years, the period demanded by Lord BURY, and has so far yielded in respect to the conditions of sale that they are subject to variation at the hands of the Board of Trade. If we understand rightly Section 2 of the amended Bill, the parties seeking a provisional order may make their own arrangements with the Board of Trade as to the terms upon which the local authority may require the undertakers to sell their business, notwith-

Digitized by Google

standing anything to the contrary in Section 27 of the original Act.

If we are right in this interpretation the most objectionable feature in the Act of 1882 will have disappeared; and it will rest with the applicants to make the best bargain they can with the Board of Trade in each separate case. It is an ungracious way of conceding an equitable principle, but it is better than leaving the opposite principle rigidly fixed by Act of Parliament. On the whole, therefore, there is much reason for congratulation at the progress made in this prolonged struggle. The Bill, under existing circumstances, is hardly likely to pass in the present Session; but this is, perhaps, not wholly to be regretted. Delay will afford time for carefully weighing the advantages and disadvantages of working under the provisions of the Act. Every year of untrammelled enterprise has proved of service to electric lighting undertakers, and has rendered them less and less eager to enter prematurely into speculations of great magnitude except on terms that are attractive and safe. Nothing less than an extension of the provisional order to twice its original duration will now be accepted, and a test application to the Board of Trade will, whenever the Bill passes, quickly reveal the conditions of purchase which that body is disposed to entertain.

CORRESPONDENCE.

CURRENT INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

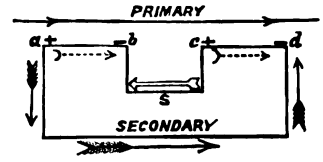
SIR: I ask your leave to reopen a correspondence under the above heading, which the force of circumstances compelled me to leave on one side last December. I am concerned in this matter partly with Mr. Sprague and others about the behaviour of induction coils, and partly with your American reader, Prof. T. A. Smith, on a far wider issue about the nature of current induction in general. It is the latter thread which I now propose to take up.

As regards the process of induction, it was my contention that there was in the portion of the secondary wire under influence a temporary slope of potential, caused by the outsetting primary current, this slope being downwards in the direction of the primary current; and I described this transient slope to a modification of the capacity along the secondary wire similar to that which takes place in the insulated cylinder familiar to us all in connection with electrostatic induction. I was led to surmise that possibly the phenomena of current and electro-magnetic induction could be traced to the first principles of electrostatic induction. If, however, Prof. Smith's experiments were made (as I presume to be the case) without an iron core, and were such as to show the unadulterated influence of current on neighbouring wire, then I am compelled to acknowledge at once (as I was all but compelled to do beforehand) that the inductive action of the primary is the working of what I may call its *magnetic faculties*, and is in no way due immediately to the *decline of potential* throughout its course.

Meanwhile, my thanks to Prof. Smith for guiding me; and, indeed, guide me is just what he has done, for his useful experiments by no means subvert those elements in my theory to which I cling so tenaciously, and for which I have claimed the support of "cogent arguments." As a step towards explaining this selection among my heretical tenets, may I say that this new theory is not a mere fancy of the imagination, without relation to known facts? The facts upon which I have built it are the great and leading facts of current induction investigated by Faraday. I have been reproached with having no facts in support of my theory. True, I have not any newly discovered phenomena to present to the world; but I offer new reasonings on old, prolific facts, never yet exhaustively dwelt upon. In the present mathematical age of science, purely physical questions such as that of the condition of a secondary wire in the "electrotonic" state are a little apt to be neglected. Faraday did not get so far as to define in what this state consisted; but at least he recognised it and christened it with a name. Meanwhile the efforts he made in this direction have been suffered to lapse into oblivion.

Now the essence of the view I have been proposing about current induction lies in this, that a secondary wire whilst under influence is in a condition similar to that of the insulated cylinder of electrostatic induction with a charged ball held near to one extremity. In the case of the cylinder the presence of the + charged ball near one end causes the electric capacity to diminish at that end and to increase at the other end, viz, that towards the wall or other object representing the earth which holds the fellow charge of −E. Now, a diminished capacity involves a rise of potential, which is adjusted only by a proportionate diminution of charge at the near end of the cylinder; hence a transfer of the "electric fluid" to the further end—all which is orthodox enough. I conceive a similar process to take place when a neighbouring wire is influenced by the outsetting primary current; but I must now avoid the error into which I was previously decoyed of supposing that the similar action is due to a similar agent (such an agent being actually present); for I now attribute the action, not to any difference of potential at each end of the inducing wire, but to the magnetic faculties of the primary current.

It was a salient feature in my heterodox view, that I assigned a reverse direction to the secondary current through the part in which the E.M.F. is generated, or, as I originally expressed it, through the portion "under influence." Such a theory is indicated by the dotted arrows in the diagram, whilst the plain



arrows show the currents familiar to all, and the broad arrow a particular result obtained by Prof. Smith, who tested the direction of the current in an internal loop *b s c*. Now, it will be seen at a glance that there is nothing irreconcilable in the relation between the broad arrow and the dotted arrows. Prof. Smith directed his experiments against the view that there was a gradual decline of potential along *ab . . . cd*, and he proved that *b* was not + to *c*, but the reverse. But on the issue, What is the direction of the current in a portion under influence? we are still awaiting evidence, for the loop tested by Prof. Smith was *not* under influence but distinctly removed from the influence of the primary current. For my part I scarcely see how to determine this question by any direct experiment, unless perhaps an electro-chemical test could be contrived. But in the meantime let us remember that the question is an open one; and on my own side of the matter arguments of an indirect kind will not be wanting.—Yours, &c.,

E. ALDRED WILLIAMS.

ELECTRIC BELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the first letter in your issue of last week signed by "The Writer of the Articles," your correspondent seems to hint that I wish to depreciate the value of his writings. I regret that he should think so, and can only say that I fully appreciate the value of his articles, and my communication was simply intended to make them (if possible) more complete by describing the latest improvements and designs that are upon the market and not noticed by him.—Yours, &c,

C. B. CALLOW.

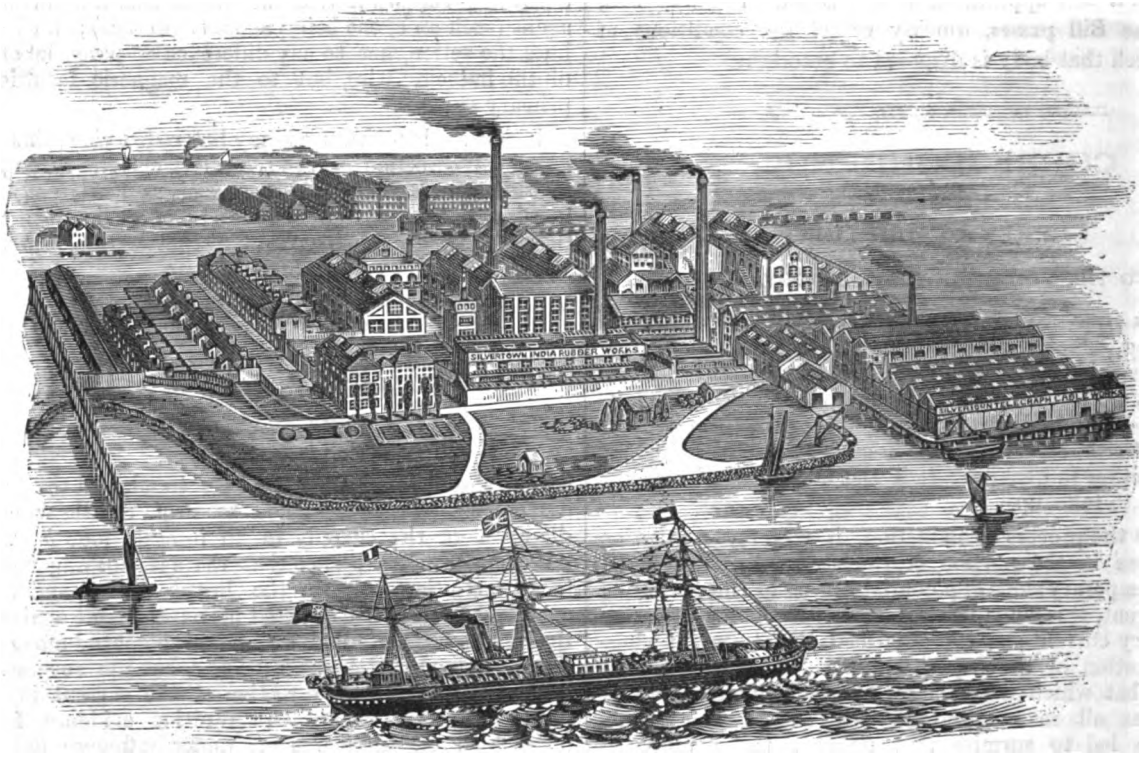
VISIT TO SILVERTOWN.

On Thursday, the 10th inst., the directors of the India Rubber, Gutta Percha, and Telegraph Works Company invited the representatives of the Colonial and Indian Exhibition to visit their extensive works at Silvertown, of the magnitude of which our illustration will give some idea. The greater portion of the guests assembled at the Temple Pier and made the journey by a boat specially provided by the company. On the arrival at the works some eight or ten smaller parties were formed from the assembled guests, and, conducted by gentlemen well acquainted with the works, were thus able to have explained to them in detail the various processes they were examining. The visitors were first led into the gutta percha department, where specimens of the crude material were seen, and the different processes of purifying and treating gutta percha were shown.

Gutta percha is principally obtained from the Malay Peninsula and the islands of the East Indian Archipelago, and is the gum of the tree *Isonandra gutta*. It was first brought to England in the year 1843. It is collected as it oozes from incisions in the tree, and is afterwards dried. When it arrives in this country it frequently contains as much as 25 or 30 per cent. of impurities, and is brought in lumps of a brown colour, having somewhat the appearance of leather, and with a peculiar odour.



The Silvertown Works of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

In the cleaning and masticating workshop the raw material as it arrives in England was seen. The boilers, the cleaners, and the masticators were shown in operation, where the natural juice of the gutta percha is removed and the material made homogeneous. Hydraulic presses are used to force the gum in a plastic state through exceedingly fine wire gauze, in order to remove the sand and bark. When the gutta percha is strained it is rolled and stored until required for the various manufactures in which it is used.

The visitors then went to the upper floor of the wire-covering department, where the copper wire conductor was being formed. On the lower floor this conductor was seen receiving its covering of gutta percha. The core of a submarine cable is formed by drawing it through a specially-constructed die containing plastic gutta percha under pressure, whence it issues coated to the required thickness; it is then hardened in cold water, and coiled on bobbins, to be afterwards inspected in order to discover any imperfections. This core—or insulated conductor—is coiled on large bobbins in two-mile lengths, and placed in a cistern containing water at a heat of 75 degrees Fahrenheit. The ends of the core are taken into the testing room for the purpose of ascertaining if the work of covering the copper with gutta percha has been successfully done and the insulation perfect.

On leaving the testing rooms the visitors were conducted to the submarine cable workshops to inspect the sheathing of the cable being manufactured to connect the West Coast of Africa with Europe. In the lower cable shop the machines were at work sheathing the shore ends and intermediate types of cable, weighing respectively sixteen tons and five tons per nautical mile. In the upper shop the deep-sea cable was seen in the process of covering the core with yarn, iron sheathing wire, and a bituminous compound to protect the iron wire from oxidation and from the *teredo navalis* and other marine insects.

On leaving the cable workshops many of the visitors went on board the telegraph ship "Silvertown" to see the cable shipped and put into the tanks, and to inspect the machinery employed in laying telegraph cables. This ship is in a few days going to the West Coast of Africa with about 2,000 miles of cable. The total cargo, including coals and stores, will weigh more than 7,000 tons. A visit was then made to the India Rubber Department, to see the treatment of india rubber in its application to various purposes. India rubber is chiefly received from the Brazils (Para, Ceara, &c.), and from Guayaquil, British India, and Madagascar. It is collected from the *Jatropha elastica*, in a similar manner to gutta percha, but with the exception of Para rubber, the impurities are greater. The first process of manufacture is to get rid of these impurities by cutting the gum into pieces and thoroughly washing and amalgamating it; after which it is dried and mixed with the materials necessary for its different purposes. It is usually mixed with sulphur, then moulded into the required forms, and exposed to a heat of about 300 deg. Fahrenheit, which causes a chemical action, completely changing the nature of the material, and fixing it in the shape designed. When the quantity of sulphur and the period of exposure to heat are increased, and the rubber is exposed to heat, ebonite or vulcanite is produced.

After inspection of this department the visitors were entertained at luncheon, Mr. Silver, the chairman of the Company, presiding. Various toasts were enthusiastically drunk, especially that of "Our Visitors," which was responded to by the representative of Tasmania.

Digitized by Google

Just before luncheon a torpedo was exploded, some of the visitors stating that Colonel Bolton must look to his laurels, for the fountains of South Kensington were nowhere beside the display occasioned. After luncheon the torpedo and electric light departments were visited, and thus concluded the inspection of the works, the guests returning by a special train from Silvertown Station to Liverpool-street.

We have only been able to describe thus briefly a most interesting visit to one of the largest works engaged in the construction of telegraphic apparatus of all kinds in the kingdom; but we are quite sure that the guests will carry away with them a vivid recollection of the immense progress that has been made in the manufacture of apparatus connected with all branches of electricity during recent years.

RESEARCHES UPON THE SELF-INDUCTION OF AN ELECTRIC CURRENT.*

BY PROF. D. E. HUGHES, F.R.S.

(Continued from page 73.)

Reactions of an Electric Current between Separate Portions of the same Conductor.

In order to distinguish two distinct effects I have defined self-induction as the effect produced by an electric current on its own portion of the wire, and mutual induction as the effect of the reactions between separate portions of the wire on each other.

The mutual induction in iron and copper wires is very different in degree, as shown by the following table:—

TABLE I.

Wires, silk-covered 1 m. in length, 1 mm. in diameter.	Comparative force of the extra currents.	Strips or ribbons, silk covered, 1 m. in length, 10 cm. wide, 0·1 mm. thick.	Comparative force of the extra currents.
Copper wire, in a single close loop, where each side is in close proximity ...	18	Copper strip, in a single close loop, where each side is in close proximity.	14
Copper wire, in a single wide circular loop	100	Copper strip, in a single wide circular loop.....	60
Copper wire, in a coil of 3 cm. diam., having ten layers in close proximity	607	Copper strip, in a coil of 3 cm. diam., having ten layers in close proximity ...	580
Iron wire (soft), in a single close loop, as above	440	Iron strip (soft), in a single close loop, as above	16
Iron wire, in a single circular wide loop	502	Iron strip, in a single circular wide loop..	60
Iron wire, in a coil as in the case of copper	570	Iron strip, in a coil as stated for copper...	578

There is a remarkable fall in the induction of a straight wire or single wide loop of a copper wire when this wire is doubled upon itself as a return wire in close proximity. The effect of mutual induction is also shown by the equally remarkable rise when the mutual induction of ten layers of a coil react on each other. This is well known, but what I believe has not yet been experimentally observed is the remarkably feeble mutual induction of iron wires, either when in parallel return in close proximity or when in coils of numerous layers, the percentage of increase of induction in a copper wire from a wide single loop to that of the ten layers being 507 per cent., whilst in iron under precisely the same conditions there was an increase of but 13·6 per cent.

That this remarkable difference as shown between the mutual induction of iron and copper wires is due entirely to the circular magnetism in the iron wire, and that the mutual reactions of the streamlets of the current in a thin flat iron conductor prevent this formation, I have proved in various ways; for if the circular magnetism is the cause, flat iron sheets which have as low self-induction as copper should be equally sensitive to mutual induction as the non-magnetic metals, for they no longer in any appreciable degree possess the protecting magnetic sheath which enfeebles the mutual reactions of iron wires upon each other; this proves to be the case, a thin ribbon of iron having the same coefficient of mutual induction as copper, and it no longer behaves as a magnetic body.

* Read at the Royal Society, May 27, 1886.

Table I. shows the difference in the mutual induction of iron wires and strips; it will be seen that when the iron is in the form of a wire the circular magnetism produces a marked difference between iron and copper, whilst in the form of flat strips the iron resembles copper (as regards mutual induction) in every respect.

Influence of Circular Magnetism.

I have shown in my late paper that an iron conductor composed of numerous fine stranded wires (as in a rope) behaves like copper, and this I regard as entirely due to the breaking up or prevention of circular magnetism; I also showed a phenomenon which I could not then explain, viz., that when an iron wire was heated to a yellow-red heat it lost its previous high specific inductive capacity and behaved like copper. The effect of heat upon magnetism is well known, consequently we can readily explain the fall in its inductive capacity by the disappearance of its circular magnetism. I found also that in thin flat strips of iron there was no change whatever in its inductive capacity at the yellow-red heat. This can now be readily explained; it behaved like copper when cold, and, having but little circular magnetism to destroy, there was no appreciable change produced, except that due to the extra resistance caused by the increased temperature of the strip, and to which copper and iron are almost equally sensitive; consequently we may consider iron (when in the form of thin flat sheets) to behave like non-magnetic metals throughout all temperatures.

Influence of Self-Induction on the Resistance of the Conductor.

A phenomenon of great importance is the effect which I have observed of the resistance of a wire being greater during the rise of the current, as in the variable period, than that measured or known during the constant flow, as in the stable period. By resistance I mean a pure ohmic resistance, a resistance which can only be measured, expressed, or balanced in ohms, and, whatever the cause, the effect is one of pure ohmic resistance.

We can imagine that at the first moment of contact there is no current flowing through the wire; its resistance is then infinite, but the current gradually increases in force until it arrives at its maximum, as in the stable period. We have thus between the moment of contact and period of steady flow a variable period wherein the resistance falls in the form of a curve from infinity to its well-known stable resistance; the telephone is unable to give the exact form of this curve directly, but it gives by the nul method comparative results as to the different duration in time of the curve in different metals.

If we take a straight copper wire 1 metre in length and balance its resistance in the stable period, we shall find only traces of a difference in its resistance in the variable period, and we can balance its self-induction by the induction balance; but if we replace the copper by an iron wire of the same length, or even a much shorter wire, viz., 20 cm., we find that in the variable period we can no longer balance the wire by the induction balance alone, but we must compensate for its increased resistance by the sliding scale, the amount of subtracted German silver wire expressing in fractions of ohms (the value of the wire being already known) the additional resistance of the iron wire in the variable period; we can thus reduce or balance the iron wire to a perfect zero, provided the current from the battery does not exceed 0·10 ampere; but with greater current there will still remain a slight muffled sound, which cannot be reduced to zero either by the induction balance or the resistance slide. It therefore became important to determine if this muffled sound was due to a difference in resistance which could not be balanced, or to the lengthened duration of the extra currents being slower than the balancing current from the induction balance; the latter proved to be the case, for on prolonging the duration of the balancing currents from the induction bridge by introducing a core of iron in its coil, the balance or zero became absolutely perfect. In this case we must choose between cores of different diameter to find one whose reaction on the time effect of the induction coil equals the retardation of the extra currents in the wire tested.

If we observe the method employed in the bridge, we shall see that the induction balance can balance the extra current of the wire X, irrespective of the position of the resistance slide M, or any relation between the sides A B and A D. But we cannot equalise the resistance of these sides except by the necessary adjustment of the resistance slide; consequently when we are forced to adjust the induction balance we are compensating the extra current, and when we are forced to move the resistance slide we are balancing resistance.

The disturbance in the bridge caused by the change of resistance of the wire tested in the variable period, causes a momentary primary current to pass through the telephone in the same direction as the extra current, and if these are not separated by balancing the extra current by an induction balance, the mixed effect would be read as a single effect of the extra current. To show the importance of separating these two effects, it is only necessary to

Digitized by Google

say that in most of the cases cited in this paper the momentary primary current due to the extra resistance greatly exceeds that of the extra current; consequently all measurements taken wherein this separation is not complete give the result of a mixed effect.

In the method which I have described, the separation of the extra current from the momentary primary current is so complete that the measures given by the induction balance and resistance slide are invariably the same for a given wire; there is no personal equation, for all observers find precisely the same values both for the resistance and for the extra current.

The method is, however, defective in measuring any small difference of resistance in the variable period in copper wires, as the induction balance itself introduces an additional but opposing resistance by the approaching of its coils, consequently any resistance which we observe is a fraction less than the real amount. To prove this we have only to use a balancing induction current produced from the battery circuit, as shown in my first paper, when we observe this small difference, and, better, observe any small difference of resistance in a straight copper wire, and greater when the wire is formed into a coil.

Soft iron wire gives a far higher resistance in the variable period than hard iron, but each wire, according to its molecular structure, has its own value; the effect increases with the diameter, ranging from 25 per cent. increase of resistance for wires of 2 mm. in diameter, to 500 per cent. for those of 6 cm.

TABLE II.—Resistance of Iron and Copper in the Stable and Variable Periods.

Wires, 1 m. in length, 5 mm. in diameter.	Comparative force of the extra current.	Resistance in ohms, stable period.	Resistance in ohms, variable period.	Percentage of increased resistance in variable period.
Copper	78	0 001284	0 001372	7
Soft Swedish iron...	234	0·008346	0·022200	166
Americ'n compound wire, copper exterior, steel interior	83	0·002247	0·002696	20
Ditto, steel exterior, copper interior...	213	0 007750	0·0248000	220

Table II. shows a few illustrative examples. The resistance is given in the fractions of the ohm, indicated by the resistance slide M, upon the supplementary resistance wire H 1.

The table shows that copper and the American compound wire coated with copper have an extremely rapid action or curve from an infinite to its stable resistance, due to their freedom from circular magnetism, whilst iron shows a comparatively slow curve.

A remarkable result will be seen where a copper wire has been coated with iron, its variable resistance being 220 per cent. above that of its stable period, and 54 per cent. greater than that of a solid iron wire.

I found in my previous researches that the resistance in the variable period could not be changed by a change in speed of a periodic or tuning fork contact maker, and that the telephone was more sensitive when the rubbing contacts were used without any regard to their frequency of interval. I also found that the telephone was far more sensitive and alone suitable for these experiments when its diaphragm was entirely free from varnish or coating, and sufficiently thick to give a clear musical dominant tone of about C or 512 double vibrations per second, the electromagnet being also as close as possible without being in actual contact. I noticed that, no matter what number of vibrations were sent, the tones given by the telephone on each side of the zero of the bridge were invariably those of its dominant note. Suspecting that the frequency of vibration of the diaphragm had a direct relation with the resistance found, I altered its note through a range of one octave by employing different thicknesses of diaphragms, and found that the results were in absolute proportion to the frequency of the vibrations of the diaphragm, the highest tone giving a perfect zero with a high resistance in the variable period, and the low tone giving its zero at a marked less resistance. Thus it was evident that the telephone selected from the mixed vibrations sent by the transmitter those which alone corresponded to its period of vibration, and that we could thus observe the effect of more or less rapid periodic contacts.

The power which vibrating bodies have of selecting from a confused number of vibrations those in accordance with their own is shown in Helmholtz's resonators, and still more as regards electrical waves in the remarkable harmonic telegraph of Elisha Gray, who proved that if the armatures of several electromagnets are made to vibrate, each with a different musical tone or rate of vibration, then we may by the use of a vibrating transmitter of a fixed rate of speed select the electromagnet alone whose period of vibrations is similar, and that we may send several different periods of vibrations at the same time without any confusion in the receiving magnets, as each electromagnet selects from the compound vibrations those in accordance with its own. This is exactly what occurs with a telephone when using a periodic contact maker, but I have found in addition that a telephone arranged as I have described, will select and respond loudly in its own clear musical dominant tone to a confused mass of rapid contacts such as those produced by a scraping contact, and which in an ordinary telephone gives only the effect of noise of not one-third the power or loudness of that produced by the tone of the musical telephone. We may thus have ten or more telephones of different musical notes, each responding separately in their own tone or all at the same time, as each diaphgram selects its own period from the confused periods of contacts sent by the scraping contact maker.

In order to verify the results, I have used in these experiments both periodic and mixed sound transmitters, but find that owing to the difficulty of keeping the periodic transmitter and telephone in perfect tune with each other, that the mixed sound transmitter is preferable, as it gives no trouble whatever, and we have more accurate results, as we then have only to keep our telephones in accord with the number of vibrations desired.

The experiments mentioned in this paper were all made with a fixed note of vibration of the diaphragm of 512 double vibrations per second. I will, however, mention a few made with varying rates of vibration, and as I propose in a future paper to give a more extended series of observations through a wider range, I will confine myself to these examples.

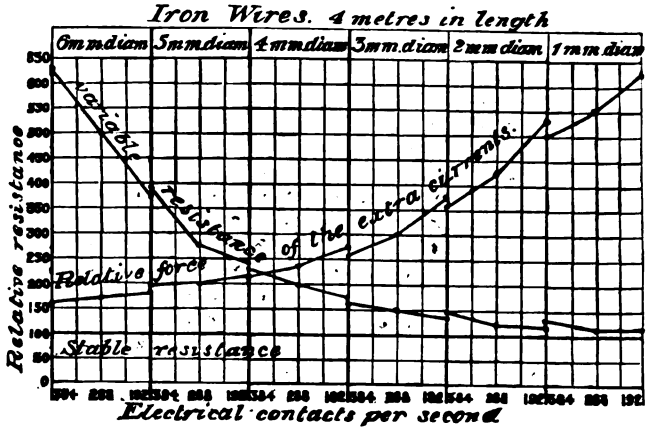


FIG. 2.

The diagram shows the results obtained on iron wires of different diameters; their stable and variable resistance were all reduced to comparative values, the stable resistance being taken as 100. Three telephones were employed, the first having the musical note of G or 768 double vibrations, the second C sharp or 576 double vibrations, and the third one octave below the first or G 384 double vibrations per second.

It will be seen that a great change in the variable resistance takes place in the range of a simple octave, and that the fall from the wires of 6 mm. to that of 1 mm. is so regular as to be almost a continuous curve, and the total curve would be probably that taken by the wire of 6 mm. in its approach to its stable resistance.

If this is the case, as future researches may show, then the resistance of this wire with the comparatively slow contact speed of six per second would still have 14 per cent. higher resistance in the variable than in the stable period, or an ordinary Morse telegraph instrument working at a slow speed of only eleven words per minute would experience this additional resistance; consequently, this effect should be easy to prove by the ordinary methods with galvanometers, and this can be accomplished as soon as we have found a method of completely separating the extra current from that due to the increased resistance, as I have already succeeded in doing by the method which I have described.

The iron wire of 6 mm. diameter shows for a speed of 384 contacts per second a comparative resistance in the variable period of 638, or more than six times its stable resistance, but with 192 contacts per second its resistance is but 371; the fall of resistance is so rapid here that for a single octave difference in the telephones, the fall is far greater than the whole stable resistance. The extra current, as well known, is proportional to the length of contact for fine wires, but in large wires the curve indicates that the extra currents have a local reaction on the cessation of the primary current.

(To be continued.)

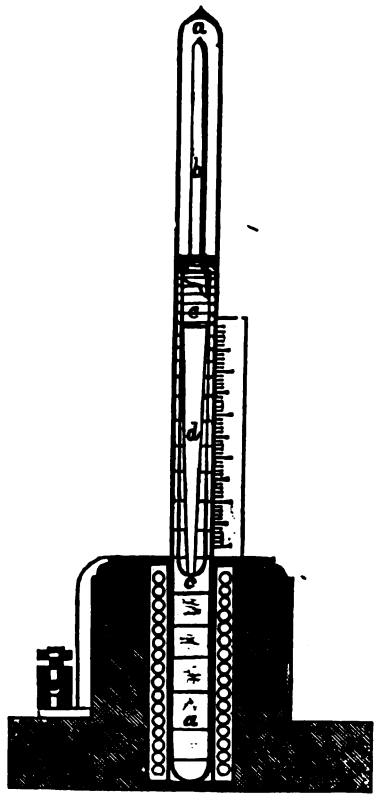
CONTRIVANCES OF THE NATURE OF AEROMETERS FOR MEASUREMENT OF CURRENTS & POTENTIALS.

The idea of balancing the attraction which a solenoid exerts on a piece of soft iron against the resistance which a fluid exerts to the lowering of a floating body has been repeatedly employed to measure currents and potentials. Karl Raab has had different arrangements of this fundamental idea patented. The figure shows one of these arrangements. In the hollow of a solenoid there is fastened a glass tube, closed at both ends, which is filled with alcohol or some other mobile liquid. On the liquid floats the glass aerometer *b c*, which contains in its under part a thin conical iron tube, *d*. When a current passes through the solenoid the attraction of the iron core causes the aerometer to sink more or less according to the strength of the current. The scale is divided empirically. The magnetic force keeps the aerometer always in the centre of the glass tube, so that it does not adhere to the sides. The wording of the patent would include a somewhat similar contrivance designed by Lalande.



It is believed that this kind of instrument may be very useful with a fitting choice of the form and quality of the iron core ; but the heating of the coil by the passage of the current may make corrections necessary on account of the alteration of the density of the fluid and of the volume of the different parts of the instrument, and it will be necessary for great accuracy to place a thermometer in it. To make the heating of the coil have as little effect as possible, it would be advisable to separate it by a layer of air from the glass tube.—*Elektrotechnishe Zeitschrift.*

PROF. FORBES' CANTOR LECTURES.

LECTURE IV.

(Continued from page 78.)

In the previous lecture we saw the means by which we could create electric currents, and we saw something of the way in which those electric currents act. It will be my endeavour to-day to show you some experiments illustrative of the enormous progress which was made during the years 1820 to 1830, resulting in discoveries which have formed the foundation of the whole of the most important developments and practical applications of electricity since that date. Previous to the years 1820 to 1830 there were but few phenomena connected with electricity really known. We knew that an electric current would heat up conductors. We knew that we could get a spark from charcoal points, and Humphrey Davy had made the celebrated experiment which led finally to the construction of the arc light. We also knew that chemical substances could be decomposed by means of an electric current. Beyond that practically nothing was known. A certain number of facts, isolated and non-reproducible apparently, had been collected. It had been found that there was some sort of connection between magnetism and electricity. But as to the nature of this connection nothing was known. It had, however, been observed that frequently on board ship, during a thunderstorm, when a flash of lightning struck a vessel the compass needle was either rendered useless or caused to point in an opposite direction—its north end pointing south, and its south end pointing north. It appeared, then, that this electric current, this passage of lightning, had some connection with magnetism. But till the year 1820 there was no clue as to what the connection between the two was. In our last lecture I showed you what an intimate connection there seemed to be between magnetism and electricity, and every step in our progress to-day will show the connection still closer. During the year 1883 there was a very grand exhibition of electrical appliances at Vienna, and I remember well in wandering round that enormous building in Vienna, where were collected the developments of electrical science in every department—in telegraphy, in telephony, in electric lighting, in electrical clocks, in short, in all kinds of electrical appliances—after having examined all the dynamo machines, arc lamps, &c., I came, in a select corner, upon a minute exhibit which made me pause with a feeling of respect and awe. When I looked at that small apparatus, and thought of the consequences which had followed from it, I say I looked upon it with respect and awe. It was simply a compass needle, placed on a stand, covered with velvet, with a glass shade over it, and above that compass needle there was the bust of the illustrious man who had made use of that simple apparatus. I need hardly say when I thought of the experiments that had been made with that apparatus, when I considered that from that single experiment the whole of the principles involved in the vast collection of electrical apparatus in that building almost immediately followed, I could not help feeling that there was something to have respect for. It is scarcely necessary to say that the exhibit I was looking at—that small compass needle—and the bust behind it, were those of Prof. Oersted, of Copenhagen. That experiment was the genesis of all that has been done in electro-magnetism since then. And I think you will be able to see this afternoon, as we take up one experiment after another, how it might have been possible almost to have foretold from that experiment a vast number of the phenomena which were discovered afterwards, and which form the fundamental principles of electrical science. The experiment of Oersted consisted in bringing a wire, through which an electric current was passing, into the neighbourhood of a suspended compass needle. Here I have a compass needle suspended on a pivot, and in my hand I hold a wire, through which I am able, when Mr. Davenport turns on the switch, to pass an electric current. [Shown] The direction of the current is shown by the arrow on this wire. The result is that, if the wire containing the current be held parallel to the needle, it should be deflected in one direction or the other, and the direction in which the magnet is deflected depends partly on the direction of the current, partly upon the position of the current above or below the needle. First, I place the current travelling from north to south, and I place the wire over the compass needle. You will then see that the north pole, which is the one towards my right, moves towards me. [Shown.] I now reverse the current, and make it travel from south to north, and immediately the motion is checked, and then a motion in the opposite direction is produced. By reversing the direction of the current I am able to reverse the direction of the deflection. [Experiment repeated.] Now let me show you what conclusion you might legitimately draw from this fact. The thing has nothing to do with the vertical position, except that the pivot being vertical the magnet can only travel in a horizontal plane. Therefore, we must not define the action as being dependent on the position of the current above or below. But we always notice this. I will give you a law which has been very largely used as a sort of aid to the memory—that if I be looking down thus, looking at the magnet, and if my body be lying in the direction of the current, so that I am, as it were, swimming with the current, the current coming in at my feet and out of my head, and if I be looking to the North Pole, I should see the north pole going to my left hand side. I will tell you another thing that follows immediately from this observation of Oersted. It follows that each one of these poles is trying to get round the current in opposite directions. When I have got the current above it, the north pole is trying to get round it, and it would go round it continuously, but it is restrained in its action by its connection with the south pole, which is at the same time trying to go round the wire in the opposite way. And, therefore, although both the north and south poles wish to go round that wire, they cannot go round in opposite directions because they are rigidly connected, and, consequently, they move into a position at right angles to the current. Therefore we see clearly enough that if we could arrange matters so that the north pole only was tending to go round the current, and the current did not extend over the south pole, then we should be able to get a continuous rotation of the north pole round the current. I think you will also agree with me that this is a conclusion that we should naturally have arrived at from the exhibit of Oersted's apparatus. I will try the experiment with a small apparatus which I have on the table here. This consists of a magnet which is in a bent form thus. [Shown.] The current comes down a pivot here, and is carried away by a wire placed in a trough of mercury here, and if our conclusion is right, that the north pole ought to travel continuously round the current, as I have already stated, then we should have a continuous rotation of this north pole round the current whenever it is turned on. The presence of the current is shown by the luminosity of that little bit of platinum wire which is bent round so as to dip into this cup of mercury. [Experiment.] I will now describe another experiment which is a still greater simplification of this, and a very remarkable one, too. Here I have a vertical magnet, which is pivoted at the top and bottom, and there is a platinum wire, as before, dipping into a cup of mercury, which carries away the current, so that the current only travels in this direction [indicated], and does not go near the south pole. In this way the north pole ought to travel round itself. [Experiment shown.] You see now that the north pole rotates round itself continuously. It appears, then, that so far as the action of a current is concerned, it is this—that there is a tendency to cause

Digitized by Google

the north pole to move perpendicularly to the direction of the current, and to cause the south pole also to move perpendicularly to the direction of the current, but in the opposite way. In other words, a current has the power of creating a magnetic force in its neighbourhood—that is, of influencing the magnetic pole. If it has the power of creating a magnetic force, we know that it is capable of doing many other things. We know, for example, that it is capable of creating magnetic poles in a piece of iron. We also know, from the experiments we made on the last day—you remember when I threw images of some iron filings upon the screen—that the iron filings in a magnetic field indicated to us the direction of the magnetic force. So you will easily see that we ought, if we sprinkle iron filings round a wire, to be able to see the lines of induction of magnetic force as it circulates round the magnetic pole. Here is a wire coming up vertically through a hole in this piece of glass. I strew iron filings on the glass, and pass a powerful current through the wire. I now project an image of the arrangement upon the screen. You observe that the filings have formed a series of concentric circles around the wire. Now, what takes place when we have a coil of wire like this? What is the condition of the magnetic force when we have a coil of wire? We know that any part of a coil through which a current is passing is tending to move the north pole round it in a certain direction—continuously round it. Every part of this coil of wire is tending to move the north pole round it, and at its centre they all combine to move the north pole through the centre of the coil. You remember that when I had the small floating battery, with its coil of wire attached, that there was a tendency on the part of the magnet to suck this coil over itself. And now we see clearly that the opposite effect is capable of being produced, and that the coil would naturally tend to create a magnetic force through its centre, and the completion of the circuit would be accomplished round itself, outside, and back again through its centre. This action can do several things. The magnetic field thus created can cause a magnetic pole to move, so that, if we have a compass needle suspended inside [indicated], it would tend to twist it at right angles to the plane in which the wires of the coil are wound—that is, parallel to the axis of the coil, the north pole being moved through the coil in one direction, and the south pole in the other direction. This is the principle of the construction of the galvanometer, one of which I have on the table here. Here we have two coils of wire, both wound in the same direction, with a current circulating through these wires. At the centre of the stand there is a compass needle which naturally points parallel to the plane of the coils; but when the current is flowing, both these coils tend to move the north pole to the right, and the south pole to the left. This is one of the actions which a coil conveying a current of electricity can produce, owing to the magnetic condition of the space in its neighbourhood. Another thing which a magnetic force can do is to create poles in a piece of iron. Thus, if I put this piece of iron into the centre of this coil, as soon as the current is switched on it becomes a powerful magnet. In order to show you this I will support a few tacks in my hand under the iron. There is no attraction at present, but if Mr. Davenport will turn on the current these tacks will be attracted, as you see. At the moment the current is broken, the tacks fall down [so], showing that this coil, with a current passing through it creating magnetic force in its neighbourhood, is also able to induce polarity in a piece of iron. A third action is due to the combined effect of the two. This coil has the power when I suspend my iron by a piece of thread in front of and co-axial with the coil, of creating polarity in this piece of iron, and thus causing the pole to move towards the coil in accordance with the rules which we have seen before. [Experiment.] This sucking action is applicable to a great many kinds of apparatus, and I am illustrating this action more as an evidence of what we might expect would come from it than for any useful purpose it served at the time. Now I have said that a study of these phenomena, resulting simply from Oersted's grand discovery, would lead us to many new facts even before we had performed the experiment, and I am going to ask you to think about a further action, in order that you may be led to one of Faraday's beautiful discoveries, and, I believe, in so thinking over Oersted's experiment we shall be following somewhat in the direction in which Faraday proceeded. Faraday never told us that he knew what he was going to get first, but always described an experiment simply as it came. He did not wish to go in for hypotheses, but simply to show effects as they came. Now it is a grand law, which we have known since the days of Newton, that action and reaction are always equal and opposite. Let me say a few words here upon this. If one of you and myself were to sit upon two chairs upon castors, and to be connected with a rope, and I were to pull you towards me, you must not imagine that you alone would be pulled along the floor towards me, I also would be pulled towards you. If you were to pull alone, both of us would move in the same way. In every case whoever seems to be doing the work there is always a reaction equal and opposite to the action. When a planet is going round the sun, the planet is drawn towards the sun by the force of gravitation. But you must not suppose that the sun is not also drawn towards the planet. It most undoubtedly is; and although the mass of the sun is so great that its movement is very small, the total amount of reaction is exactly equal to the action of the earth towards the sun. When a stone falls from the hand to the ground, it falls by the force of gravitation, the earth attracting it; but the stone is at the same time attracting the earth, and the earth moves in the opposite direction to the stone, and the total action which we observe by the fall of the stone is exactly equal to the reaction in the motion of the earth upwards towards the stone, only the mass of the earth is so great that its motion is totally insensible. With these preliminary remarks, let us return to the experiments we have been considering. We find that a magnetic pole tends to rotate round an electric current. We know that action and reaction are always equal and opposite, and therefore we know, before we try the experiment, that a current will tend to rotate round a magnetic pole. Now, this is the sort of argument which I always imagine to myself Faraday must have used in studying Oersted's experiment, and leading up to the beautiful experiment which he produced, showing that an electric current rotates round a magnetic pole. This apparatus [indicated] is exactly the converse of the smaller apparatus which showed us the other experiments. Here I have a vertical magnet, with its south pole uppermost. Pivoted on the top of the magnet is a conductor, a piece of copper wire in fact, which travels parallel to the magnet, and dips down into a trough of mercury. The current enters parallel to the magnet, inside the trough of mercury, goes up to the top of the pole, traverses the pivot, goes down the wire which is parallel to the magnet, and outside it; then the current goes into the trough of mercury, and goes through a wire back to the battery. Now, when we turn on the current, we shall find that the wire is rotating round the pole, showing the accuracy of the principle that the action and reaction are equal and opposite. I will now simply show the effect of reversing the polarity. You notice the direction of rotation in the present case. If you were looking down upon it you would see that the direction is the same as that of the hands of a watch. I have now reversed the magnet and put the north pole uppermost, and we shall find that the current, instead of going in the direction of the hands of a watch, will tend to go in the opposite direction. [Shown.] This experiment led Faraday to a large number of very beautiful experiments, all illustrating the same points. But the general fact remains that, when we have an electric current in a magnetic field—that is to say, in a part of space where there is a magnetic induction—there is a force tending to move that current, and tending to move the magnet. A little more I should like to say about the direction. I told you when I was using the suspended magnet that the law for the direction of Oersted's experiment was that if you placed yourselves on a conductor carrying a current, with your head pointing in the direction of the current, and looked towards the north pole, that then you would see the north pole move to your left. Another way is: Place the face of your right hand towards the north pole, and point your thumb in the direction of the current; that is to say, the current is going down your thumb from the point of your thumb towards your hand, and the palm of your hand is facing the north pole, then your fingers will show the direction in which the north pole of the compass needle tends to move. That is perhaps a little simpler than the way I previously described it. Another way of remembering it has been put very justly and very properly in this way: Suppose that you are using a corkscrew, you turn it round in the direction of the hands of a watch, and at the same time the point is moving downwards. That gives you a relative idea between the direction of rotation and motion perpendicular to the plane of rotation. Then I would say that when a current is going in the direction in which a corkscrew moves—the forward direction—then the magnetic pole will be seen to turn in the direction in which the corkscrew turns. It is very easy to choose one of these rules, and fix upon it, but you are very apt to get confused if you do not fix on one. When you want to know in what direction a current moves, you have always to remember that action and reaction are always equal and opposite. Therefore, if, under these circumstances, the north pole tends to move in one direction, you know that under the same circumstances the current tends to move in the opposite direction. I am now going to another set of phenomena. The action of this coil upon a piece of iron is to magnetise it. Its action upon a piece of magnetised iron is to make the magnet move. The action of this coil is to create a magnetic field. The action of this coil is thus identical with that of a magnet. A magnet could be constructed of definite proportions, which would behave exactly the same way as this coil does. Now, if this coil attracts a magnet, and since another coil will act as a magnet, it is perfectly clear that two coils ought to attract each other. Each of these two coils is acting as a magnet [shown], and therefore they ought to be able to attract or repel each other, according to the position of their axis. They ought to be able to twist each other round a pivot, and this is part of the development of those grand researches which were undertaken by the French philosopher, Ampère. Ampère saw that there ought to be some action between conductors which carry currents of electricity, and on studying these actions he was able to bring out some very general laws. He aimed at putting his conclusions in a certain definite form. He supposed that when we have two circuits—whether they are coils or whatever they may be—with electric currents, he supposed that each little bit of a current in the one circuit was acting according to some force or another upon each small bit of the current in the opposite circuit, and that the action that we observed was the same upon all of those little independent currents. This was a very difficult way of attacking the problem, and he did attack it from a purely mathematical point of view. He showed that two bits of current parallel to each other either attracted or repelled each other according as the direction of the current in the two were the same or opposite. I have the means of showing this to you by a flat coil of wire which I have here suspended. This wire is simply wrapped round a central pivot until we get a spiral such as you see. [Indicated.] This is of considerable size, exposing a considerable surface which might be subject to an attracting or repelling influence. The suspension of this coil is effected by means of the wire itself. The two ends of the coil are conducted up to the beam over my head, and thence the wires go to the battery, so that I am able to send a current circulating through that coil. I have here another coil or spiral exactly similar to the one I have been describing. I have a separate battery also attached to this spiral. [Indicated.] The current is now circulating through the coil which is suspended. But there is no current at the present moment circulating through the coil which I hold in my hand. I now switch on the current in the second spiral, taking care that the connections are so made that the currents in the two spirals are in the same direction in adjacent parts. You observe

Digitized by Google

that the spirals are attracted towards one another. [Experiment.] There, then, was a case in which the currents of electricity were circulating round these two coils in the same direction, and the parallel currents going in the same direction attracted each other. I will now ask Mr. Davenport to reverse the direction of the current of electricity, so that the currents in the two coils will be going in opposite directions. I will now hold my coil close to the suspended one, and you see there is a violent repulsion, and when I bring the two coils together they try to slide over each other and to get away from each other. There we had repulsion. I will now simply turn my coil round so as to bring the opposite face of the spiral towards this side, and ask Mr. Davenport to put on the current in the same direction as before, and you see there is attraction. You see that when I reverse the position of the coil I obtain the same effect as if I had reversed the direction of the current in the commutator. I will now show you by an apparatus on the table the truth of Ampère's conclusions—namely, that two parallel currents attract each other when they are going in the same direction, and repel each other when they are going in opposite directions. The apparatus which I have here consists of a vertical column, supporting at its top a pivoted horizontal wire, which is then bent downwards and dips into a trough of mercury at the base of the vertical column, so that this rectangular wire is perfectly free to rotate about a vertical axis. I shall be able to put on a current immediately, and the direction of the current I have carefully observed before—the current coming from the copper plate and going to the zinc plate through the external circuit comes up through this part. [Indicated.] The current of electricity in the wire which I hold in my hand is also going in the direction of the arrow which is attached to the conductor. The currents are now circulating, and I will keep the arrows pointing in the same direction. Both the currents are going in the same direction, and I bring this one near to the suspended one, and you see the action produced, causing a rotation of the whole apparatus round the central pivot, so as to bring that portion of the moveable circuit in which the current flows upwards as close as possible to this wire in which the current is also flowing in an upward direction, thus showing that two currents going in the same direction attract each other. I will now steady it, and hold my current in the opposite direction, and cause the current which I have in my hand to flow downwards, while that in the other is going upwards, and I think we shall be able to see a decided repulsion. [Shown.] The two main principles of Ampère's experiments are proved to be, very true, namely, that two parallel currents attract or repel each other, according as the direction of the current is the same or opposite. There is another part of Ampère's conclusions to which I will also direct your attention. He also showed us that if we take two wires, both carrying currents, and suspend them so that they are free to rotate about their centres, they will tend to attract each other if the currents are both going from the point of intersection. They will also attract each other where they are going towards the point of intersection. But if I have two wires in which the directions of the currents were like that [indicated on the board], in which one is going towards the point of intersection and the other is going from the point of intersection, Ampère showed that then there would be repulsion between these two. I have an apparatus which will show you this action very well. It is a very beautiful apparatus, which I happened to come across the other day. I have two coils of wire, both on vertical pivots, and capable of rotating about that vertical axis. A current of electricity can be independently sent through these two coils. Both of them in rotating are able to make contact with mercury which is contained in little cups. The ends of the one coil always dip into the same cups of mercury, and therefore the current always acts in the same direction through that coil. But the ends of the other coil dip into a cup which has a partition, and the mercury which is in the cup rises by capillary force above that partition, but not so as to flow over. Thus, we have two mercury sections into which the two wires can dip, and this acts as a commutator tending to reverse the action of the current. Thus the force is converted into repulsion, tending to continue the rotation. By this very ingenious device we can get continuous rotation of these two coils round the vertical axis, the two rotating in opposite directions. That illustrates the action which I have just been describing, showing the attraction or repulsion between these two cross conductors at the top and bottom of the pivot, combined with the attraction of parallel conductors which are at the sides. In conclusion, I will show you an experiment illustrating the same laws as Ampère worked out by means of another apparatus which I have there. But previous to doing so I wish to show you some of the models which have been lent to me, which illustrate the fundamental principles of Ampère's theory of magnetism. I have already shown you that a coil acts as a magnet, and the direction of a current in the coil is shown by these models. [Having explained the models referred to.] I shall now, in conclusion, show an experiment which further illustrates the attraction of currents for each other in a very simple way. I have upon a stand a spiral of copper wire forming a vertical coil freely suspended from its top. The lower end of the copper wire dips into a small vessel of mercury. When I turn on the current we know that there will be attraction between each one of these spirals and its neighbour, and the attraction is simply due to the creation of a magnetic field in the way in which we have evolved these views from Oersted's experiment. By the creation of a magnetic field there is attraction produced between these spirals. But if I were to put a piece of iron into the centre of it the intensity of the magnetic field would be increased. Whenever there is a magnetic field created there is attraction between the coils of this copper wire. If a current is passing through a spiral the current of electricity will be stopped as soon as this action has ceased to take place. Immediately the current ceases the spiral assumes its normal state.

(To be continued.)

ELECTRIC LIGHTING ACT, 1882, AMENDMENT BILL.

The following is the amended Bill, recommended by the Select Committee of the House of Lords, and intituled "An Act to Amend the Electric Lighting Act, 1882:"—

1. Section twenty-seven of the Electric Lighting Act, 1882, shall be read and construed as if the words

> "within six months after the expiration of a period of twenty-one "years, or such shorter period as is specified in that behalf in the "application for the Provisional Order or in the special Act, from "the date of the passing of the Act confirming such Provisional "Order or of such special Act, and within six months after the "expiration of every subsequent period of seven years, or such shorter "period as is specified in that behalf, in the application for the "Provisional Order, or in the special Act,"

had been originally ommitted from the sixth and following lines thereof and in lieu thereof the following words had been therein inserted:

> "within six months after the expiration of a period of forty-two "years, or such shorter period as is specified in that behalf in such "Provisional Order or special Act from the date of the commence-"ment of the Act, confirming such Provisional Order or of such "special Act, and within six months after the expiration of every "subsequent period of ten years, or such shorter period as is specified "in that behalf in such Provisional Order or special Act."

2. Notwithstanding anything in section twenty-seven of the Electric Lighting Act, 1882, the Board of Trade may by any Provisional Order to be made by them under that Act, if they think fit, vary the terms upon which any local authority may require the Undertakers to sell, and upon which the Undertakers shall be required to sell to such local authority their undertaking or so much of the same as is within the jurisdiction of such local authority under the said section, in such manner as may have been agreed upon between such local authority and the Undertakers.

3 (1.) Where in any case any electric line or other work may have been laid down or erected in, over, along, across, or under any street, for the purpose of supplying electricity, or may have been laid down or erected in any other position for such purpose in such a manner as not to be entirely enclosed within any building or buildings, or where any electric line or work so laid down or erected may be used for such purpose otherwise than under and subject to the provisions of a license, order, or special Act, the Board of Trade, if they think fit, may, by notice in writing under the hand of one of the secretaries or assistant secretaries of the Board of Trade, to be served upon the body or person owing or using or entitled to use such electric line or work, require that such electric line or work shall be continued and used only in accordance with such conditions and subject to such regulations for the protection of the public safety and of the electric lines and works of the Postmaster-General as the Board of Trade may by or in pursuance of such notice prescribe, and in case of non-compliance with the said regulations then the Board of Trade may require such body or person to remove such electric line or work: Provided that nothing in this sub-section shall apply to any electric line or work laid down or erected by any body or person for the supply of electricity generated upon any premises occupied by such body or person to any other part of such premises.

(2.) Where in any case any electric line or work is used for the supply of electricity in such a manner as to injuriously affect any telegraphic line of the Postmaster-General, or to affect the telegraphic communication through any such line, the Postmaster General may, by notice to be served upon the body or person owning or using or entitled to use such electric line or work, require that such supply be continued only in accordance with such conditions and regulations for the protection of the telegraphic lines of the Postmaster-General and the telegraphic communication through the same as he may by or in pursuance of such notice prescribe, and in default of compliance with such conditions and regulations the Postmaster-General may require that the supply of electricity through such electric line or work shall be forthwith discontinued. Provided that nothing in this sub section shall apply to the supply of electricity through any electric line or work laid down or erected under and subject to the provisions of any license, order, or special Act, or which may be used in accordance with any conditions or regulations prescribed by the Board of Trade by or in pursuance of any notice given by them under this section.

(3.) If any body or person fails to comply with the requirements of any notice which may be served upon them or him under this section, such body or person shall be liable to a penalty not exceeding twenty pounds for every such offence, to be recovered summarily, and any court of summary jurisdiction, on complaint made, may make an order directing and authorising the removal of any electric line or work specified in such notice by such person and upon such terms as they may think fit.

(4.) Any notice authorised to be served under this section upon any body or person may be served by the same being addressed to such body or person, and being left at or transmitted through the post to any office of such body or the usual or last known place of abode of such person, and any notice so served by post shall be deemed to have been served at the time when the letter containing the notice would be delivered in the usual course of post, and in proving such service it shall be sufficient to prove that the letter containing the notice was properly addressed and put into the post.

(5.) In this section terms and expressions to which by the Electric Lighting Act, 1882, meanings are assigned shall have the same respective meanings, provided that the term "street" shall include any square, court, or alley, highway, lane, road, thoroughfare, or public passage or place whatever, and the expression "telegraphic line" shall have the meaning assigned to it by the Telegraph Act, 1878.

(6.) Nothing in this section shall apply to any electric line or work

Digitized by Google

of the Postmaster-General, or to any other electric line or work used or to be used solely for telegraphic or telephonic purposes.

4. This Act may be cited as the Electric Lighting Act, 1886; and the Electric Lighting Act, 1882, and this Act shall be read and construed together as one Act, and may be cited together for all purposes as the Electric Lighting Acts, 1882 and 1886.

COMPANIES' MEETINGS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The fifth ordinary general meeting of the Consolidated Telephone Construction and Maintenance Company (Limited) was held at the Terminus Hotel, Cannon-street, on the 10th inst. Mr. C. L. W. Fitzgerald presided.

The SECRETARY (Mr. Charles Curtoys) read the notice convening the meeting and the minutes of the last general meeting. The report, which has been dealt with in *The Electrician*, was taken as read.

The CHAIRMAN: Gentlemen, I hope I may be permitted to congratulate the shareholders on the improved aspect of the affairs of the Company. When I look back two years ago, and consider the position the Company was then in—how really hopeless everything seemed, with no money in the bank, and debts everywhere—and when we examine this balance-sheet in comparison with that of 1884, I think we have really the greatest cause for congratulation. Looking back to 1884, I see that the gross profits for that year were £5,600, and of that £5,000 was absolutely a compromise with the United Company; therefore, apparently, the manufacturing profits for that year were £600, while in the past year, as you see in the statement before you, they were £11,438. That item, too, would have been nearly £1,000 larger but for a question raised at the last moment by the auditors of the United Company as to the price of certain instruments. As far as I am aware, the Board of the United Company are sitting at this very moment to decide that matter, and I have reason to hope that the question will be decided in our favour. We propose that that £1,000 should be written off against the goodwill and patent rights. The next point I would attract your attention to in the report is a note as to the interest and dividends accrued on the holdings of the subsidiary companies. We have taken no credit whatever for that, though I think there is already something like £1,400 due, the greater part of which, I think, will be paid. The Austrian Company will certainly pay, and the Edison-Gower-Bell Company will probably pay a part of that interest. That, I think, is a matter of considerable importance to us, for you must remember that in the future we are looking to getting dividends out of our subsidiary companies. Further down in the balance-sheet you will notice plant and machinery, £3,097, and you will see that we have written off a considerable sum on that item. We have now got in the factory some more improved machinery from America, and, consequently, our machinery is in absolutely better condition than last year, and stands only at the same cost. As to our stock of instruments, &c., that stands at £3,303. The very tip-top firm in the electrical world in Germany have written us a letter, in which they say of some samples we submitted that the tests they have made with our instruments "prove that they may be classed among the very best that ever came under their notice." When I tell you that, and also that our stock is all of that kind, you may imagine that I look with some degree of satisfaction on that item. Lower down in the balance-sheet there is an item of £11,590 owing to us by subsidiary companies. That item includes a large sum which is due to us by the River Plate Telephone Company—£9,500. I will say no more on that head than you have seen in the report—that we believe we have at last come to terms of amalgamation with the opposition; and that to me is very gratifying, because throughout these fights the Consolidated Company has had to support the River Plate Company, through thick and thin, in cash, instruments, and stores. I do not think I need allude further to that side of the balance-sheet. Our investments are all going on well. On the debit side of the revenue account we have done everything we possibly can to reduce the expenditure. I think you will find that every item there shows a reduction as compared with last year. There are, however, four items which I should like to attract your attention to, and they are items which I do not think will occur again next year. They are—travelling expenses, £194; expenses in connection with Australian lawsuit, £167; commission on the sale of River Plate debentures, £280; and accountant's special charges for preparing balance-sheets, &c., £40. Those items in round figures come to something like £700. I only hope that in the next balance-sheet we present to you those items will not be there, and consequently, instead of the expenses being £3,695, they will be under £3,000. I do not think I need say anything more on the figures. The gross profits for the year amounted to £13,473, and I may say that that profit has been collected from all parts of the world, from a few of our colonies, and I was extremely gratified, I must say, at getting two orders from America. I did not, I must confess, expect that we should go into the enemy's country in that way, but we did so, and I hope and trust that we may get more orders from that quarter. Our business is slowly and steadily extending, and I attribute that fact to the absolute goodness of our manufactures. I could show you heaps of testimonials on that head, all of which are very gratifying to the Board. In addition, we are really supplying the subsidiary companies in England with certain articles—magneto bells, and other little bells, and so on, which all mean profit to us. We have started agencies in Madrid, Cadiz, and Naples, and I think I may say that in course of time these agencies will become very valuable outlets for our business. At first I always find abroad the same thing—the price is too dear; but within the last six weeks we have been asked whether we would undertake to erect an exchange in a town in Spain, and from that it would appear that they were beginning to recognise the fact that superiority of instruments amounts to something. You will notice that we have obtained a return of income-tax—that some money we had paid we have got back. The next item is the lawsuit which Colonel Gouraud has started against the Company for his fees. We are advised that we have got a very good

THE UNITED TELEPHONE COMPANY (LIMITED), AND ITS SUBSIDIARY COMPANIES.

The following particulars of capital, &c., and price list have been sent us by Messrs. Bell, Begg, and Cowan, of 10, North St. David-street, Edinburgh:—

† Small number of shares received 6%. (Note—25,000 6% preference shares, £1 each, 10s. paid, were originally used, but have since been converted into 5% preference shares of £1 each, fully paid, at the rate of 120 per cent.)

Digitized by Google

defence indeed for a very considerable portion of the claim that Colonel Gouraud brings against us. You will observe that the directors intend to ask you to permit us to assist the Edison-Gower-Bell Telephone Company in protecting the patent rights owned by that company in Belgium. That is a very, very important question. I could not tell you how much the sum of money involved in it is, but when I tell you that our greatest opponent, the manufacturing company over there, are turning out large numbers of instruments, every one of which is an infringement of the patents held by the Edison-Gower-Bell Telephone Company you will realise that it is an important matter to us that, if possible, we should stop these infringements. Of course, you may rest quite assured that we shall not spend a penny more than is necessary, and we shall only go into this matter if we feel our ground very safe. Law, of course, is a very uncertain thing. You never can say what is going to happen in a law suit. This particular Edison patent, however, is the master patent in England and also in America. We are, therefore, going to propose a resolution to the effect that you allow us to assist the Edison-Gower-Bell Telephone Company. I should tell you that if we assist the Edison-Gower-Bell Company it will be on the understanding that we get half the profit made on the transaction—half the loss and half the profit. I am now coming to what, in my mind, is the most satisfactory part of the whole report—that is, the amalgamation of the River Plate Telephone Company. I think I had better say as little as possible on that point, as we have only signed the preliminary agreement, and therefore it is possible that I might say something that would do us no good. The next paragraph refers to the increase in the subscribers and rental of the subsidiary companies, and that is a subject which ought, perhaps, to be regarded by the shareholders as equally beneficial. I do not know whether any of the shareholders have examined this report very carefully as far as regards adding up the amount of the ordinary shares, the preference shares, and the debentures that we hold in the various companies; but if they do so they will find that we, the Consolidated Company, hold £66,000 in these three companies that are mentioned. Now, these are beginning to return us money, and if I mistake not they will this year return us more money, especially if this River Plate amalgamation takes place; and I am even hopeful that in the future the large sum which stands here—which is taken at absolutely nothing—£222,580 in the ordinary share capital of the subsidiary companies, may return us some income. In the case of the Austrian Company, I am quite certain that they will do so in course of time, and I believe the River Plate Company will also if the amalgamation takes place. Consider for a moment what that £66,000 of debentures and preference shares means. Even if we only get 5 per cent. on that amount it would mean that the whole of our fixed charges would be paid by that return, which would also mean that we should be able to divide up every penny profit on the manufacture of instruments. As you know, I have always had my eye fixed on these subsidiary companies. They must be pushed at all hazards, because they mean that we shall eventually receive large dividends. Anyone, I think, who knows anything about the telephone will at once realise that people do come forward for it in the most marvellous manner. If I return to this Austrian report, I may say that two years ago—18 months ago, even—we had only 600 subscribers there, and now we have got 1,373 subscribers. I assure you that they are coming forward almost too rapidly for us in Austria, because you cannot put up wires and instruments and so on without capital, and these people are coming forward so rapidly that there is some difficulty in finding the capital that is requisite to meet their demands. While on that point I would say that the Board of the Austrian Company propose issuing some 6 per cent. preference shares. If the shareholders in the Consolidated Company wish to assist the Austrian Company and also themselves, they will assist the Austrian Directors by taking some of these preference shares. My father and I have a considerable stake in the Austrian Company, but personally I feel disposed to put some more money in it, as I think it is as good a thing as I know of. I hope it you receive a circular from the Austrian Company you will—some of you at any rate—respond by taking some of the shares. He concluded by moving the following resolution:—"That the statement of accounts and balance sheet, and the report of the Directors as now submitted to the meeting be received and adopted, and that a final dividend of 2½ per cent. be paid, making with the interim dividend previously paid, 5 per cent. for the year ended March 31, 1886."

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the motion.

Mr. KLENCK asked what the probable cost of the litigation referred to by the Chairman would be, and what would be the probable result.

The CHAIRMAN: We have already gone a good deal into this question before even dreaming of bringing it to your notice. So far as we know, we think the probable cost would be about £2,000. The probable profit I really could not tell you. It means very many thousands of pounds as you can imagine for yourselves. The United Telephone Company have the patent rights for England, and if the Edison-Gower-Bell Company get the patent rights for Belgium it will be a very "big" thing, because these infringers would have to pay us compensation for what they have done in the past. That is the Belgian law, I know, for I have studied it. You may be certain that we should not recommend you to go into anything unless there were a prospect of our obtaining something very tangible.

Mr. KLENCK: Do I understand that our total contribution to the cost would be about £2,000?

The CHAIRMAN: No, our share would be £1,000. The total cost would be about £2,000. In answer to another shareholder he stated that, as the revenue account showed, they had received in cash by way of dividends and interest on investments £1,588, which did not include interest accrued. They had transferred the £6,000 reserve against the general business of the Company instead of against a particular item.

Mr. TRAVERS asked whether the opposing company in Belgium were rich, or were worth "powder and shot?"

The CHAIRMAN: Well, gentlemen, I only wish we were as rich.

A SHAREHOLDER pointed out that the Belgian Company alluded to had been supplying instruments not merely in Belgium, but all over Europe.

The CHAIRMAN then put the motion in the usual way and declared it carried unanimously. Continuing, he said: The next resolution is: "That the Directors be authorised to take such steps as they may think desirable in connection with the Edison-Gower Bell Telephone Company of Europe for the protection of their patent rights in Belgium."

Mr. KLENCK: May I add, "At an expense not exceeding £1,000?" ["No, no."]

The CHAIRMAN: I think that would be hazardous. You may rely upon it that we shall not spend more than we can possibly help.

Sir A. ARMSTRONG seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed the re-election of the retiring Directors, Sir A. Armstrong and Messrs. A. H. Baker and H. Grewing.

Mr. KLENCK: Do they all attend?

The CHAIRMAN: I will say this for the Board that I have the pleasure of presiding over—that I think it is quite exceptional for any member not to attend.

Mr. JOHN TAYLOR seconded the resolution, which was carried unanimously.

On the motion of Mr. T. LLOYD, seconded by Mr. FELDHEIM, Mr. J. G. Griffiths, F.C.A. (of the firm of Messrs. Deloitte, Dever, Griffiths, and Co.), was re-elected an auditor; as was also Mr. A. E. Green, on the motion of Mr. R. E. WYATT, seconded by Mr. GARDINER.

Mr. LLOYD then proposed a vote of thanks to the Chairman and Directors. He thought that after the very flattering statement which the Chairman had made, they would all agree with him that they owed something more to the Chairman and the Directors than a mere vote of thanks, especially so when they looked back on the former position of the Company. Only two years ago they were in such a position that they were practically losing their manufacturing business, their capital was gone, and their shares were down at 2s 6d. Their position now was very different, and as the result of last year's working the Directors were enabled to pay a dividend of 5 per cent. Their business was also rapidly improving, and they saw that the subsidiary companies were coming forward rapidly to the front; while, if they looked at their prospects, he thought they were even better than the Chairman—in his cautious anxiety not to raise their hopes too high—had said. They all appreciated the Chairman's caution, but they could see by their accounts that the position of the Company was most gratifying; and what made it all the more gratifying was that the change that had taken place, in so short a period as two years, was not due to any fluke or any outside incident. It had simply been brought about by thoroughly good management. They had now a Board who had proved for two years that they fully deserved the warmest thanks of the shareholders. There were one or two points to which he especially desired to draw their attention. The Chairman had stated that practically if things went on smoothly, as there was every prospect of, their dividends and interest from the subsidiary companies would cover the current fixed expenses of the Consolidated Company, so that the whole of their manufacturing profit would be divisible among the shareholders. He believed he was correct in saying that the organisation of their factory was such that they did not require to lock up their capital—that practically as soon as they were called upon to pay for goods they themselves received payment for them. They had therefore no real liability. He believed he was correct in that statement.

The CHAIRMAN: There is a certain sum of money locked up in stock, of course, but that is continually being used up and replaced. That is the ordinary course of business. We are not locking up money in useless, obsolete stock. We keep as little stock as possible, so that we can always be ahead of the trade, so to speak, in all improvements.

Mr. LLOYD said that what he specially meant was that they did not need to invest in any large amount of stock.

The CHAIRMAN: No.

Mr. LLOYD, continuing, said that the organisation of their property was such that they did not need to lock up thousands of pounds in order to execute orders when they came in, and the payments which they had to make were met by what they had to receive. The amount due to them was £18,000, of which £8,000 would be payable very soon, and might be regarded as a perfectly good debt. The £9,500 to which the Chairman had referred was owing by a company of which he (Mr. Lloyd) happened to know something, and he thought he could safely say that it would be paid by-and-bye.

Mr. KLENCK seconded the motion, which was carried unanimously.

The CHAIRMAN, in reply, said it was very gratifying to his colleagues and himself to find that their services were appreciated by the shareholders. He could only say that they meant to go on in the future as they had in the past. He might add that they would post the dividend warrants this week.

The proceedings then terminated.

THE SCHOOL OF SUBMARINE TELEGRAPHY AND ELECTRICAL ENGINEERING.

ESTABLISHED IN 1868.

12, Princes Street, Hanover Square, London, W.

Manager: Wm. LANT CARPENTER, B.A., B.Sc., F.C.S.

THIS Establishment is not only the largest School devoted exclusively to Electrical Engineering in its widest application, and is supplied with numerous dynamo machines, lamps, artificial cables, &c., it is also the only one in which a lengthened experience of the difficulties and requirements of an effective course of tuition and training has led to success, in supplying capable men in every branch of applied Electricity. Since the opening of the School in 1868 upwards of 3,000 Pupils have passed through the course. At the end of the course of instruction, an Examination for the CERTIFICATE OF THE SCHOOL is conducted by an Examiner of very high standing, unconnected with the School. Copies of Testimonials from gentlemen of the highest eminence, both as Scientific and Practical Electricians, can be had on application.

TESTS MADE AND REPORTS FURNISHED.

For full prospectus, terms, &c., apply to the Secretary, 12, Princes Street, Hanover Square, W.

THE

THOMSON-HOUSTON SYSTEM OF ARC LIGHTING.

Extract from the "Times," Saturday, June 5th, 1886:—

"THE EDINBURGH INTERNATIONAL EXHIBITION."

* * * * * * * * * * * * * * * * *

"Electric lighting forms so important a feature of the Exhibition that some notice of the different systems employed may be useful."

* * * * * * * * * * * * * * * * *

"There can be no doubt that, both for brilliancy and steadiness, the palm must be given to the THOMSON-HOUSTON lamps. The grand hall and the picture galleries are as brightly and as pleasantly lighted by night as they are by the noonday sun. Between the other systems of arc lamps I cannot venture to discriminate. They are all good, though none of them can be compared with the THOMSON-HOUSTON SYSTEM."

LAING, WHARTON & DOWN,

8 and 9, Holborn Viaduct, London.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 11th inst. amounted to £2,756.

AMERICAN EXHIBITION.—President Cleveland has accepted the presidency of the American Exhibition, to be opened next year at South Kensington.

STRIKE AT EDISON'S.—We understand that the dispute which resulted in a temporary strike has been arranged, and the strike has come to an end.

MATHEMATICAL SOCIETY.—A paper was read at the last meeting of this society entitled "Electrical Oscillations on Cylindrical Conductors," by Prof. J. J. Thomson, F.R.S.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 11th inst. were £2,194, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

TELEPHONE GUIDE BOOK.—The National Telephone Company have issued their guide book, containing a list of the subscribers to the Glasgow Exchange, for the month of June, which, as usual, is replete with information in regard to the service of the company.

MINING INSTITUTE OF SCOTLAND.—At a recent meeting of the members of this institute an interesting paper describing a new American method of indicating temperature, steam pressure, &c., by means of electricity was read by the secretary, and led to an important discussion.

NEW COMPANY.—A new company is being promoted at Bradford with the object of enabling the shareholders to provide lighting by electricity to certain detached blocks of buildings. The prospectus indicates that the company is intended more as a co-operative venture than an ordinary business company.

THE NEW TARIFFS.—The Eastern Telegraph Company has issued a card giving a complete list of its rates to come into force on the 1st of July. Important reductions of tariff will be made not only to all countries in Europe, but also to India, Siam, Cochin-China, China, Manila, Japan, Australia, Tasmania, and New Zealand.

ELECTRIC LIGHT IN PARIS.—The preparations for the electric lighting of the Exposition de la Société des Sciences et Arts Industriels are being actively carried on by M. H. Fontaine, who is ably assisted in the work by M. G. Fournier. The number of Jablochkoff candles to be installed in the Palais de l'Industrie is fixed at 160.

ELECTION INTELLIGENCE.—Mr. John Pender, chairman of the Eastern Telegraph Company, has decided to oppose Mr. H. Campbell-Bannerman in the election for the Stirling Burghs. Mr. John Denison Pender, son of Mr. John Pender, will come forward for the Wick Burghs as a Unionist Liberal against Mr. J. Macdonald Cameron, the sitting member.

ELECTRICAL SUBWAYS.—The members of the Commission on Electrical Subways in New York state that the mileage of wires in that city overhead reaches 14,556 miles, to which must be added 1,006 miles underground, giving a total of the mileage in use, according to the statements made by the various electrical companies, of 15,562.

TELEPHONE AT GIBRALTAR.—The English Government, it is said, have authorised the installation of a telephonic system at Gibraltar. The concession has been accorded to Messrs. Spagnoletti and Crookes, who will follow the system generally adopted in England. The subscription will be 250fr. per year. An office will be specially fitted up for commercial men upon the quay.

ELECTRIC LIGHTING AT BIRKDALE, LANCASHIRE.—The Local Board for the district of Birkdale invite tenders for an installation of the electric light for lighting the public lamps of the district. Applications for particulars must be made not later than the 26th instant. Tenders are to be sent in, free of cost, on or before the 24th July next. Full particulars will be found in our advertising columns.

CRAIG-Y-NOS CASTLE.—The residence of Madame Nicolini—as we must now call her—better known as Madame Patti, is lighted by the electric light. A gas engine of six horse-power is used for driving the dynamo generating the current. The castle is lighted by about 150 Swan lamps, most of the rooms, except the bed rooms, being so lighted. Besides the electric light, a small gas works is connected with the castle, supplying the gas required for cooking purposes.

WHO IS THE MAN ?—Our American namesake says the battle in Detroit between the Brush and the Thomson-Houston electric light companies was waged with all the earnestness of a Continental strife. Some hot shot was delivered by both sides, but the hottest thing was the undisputed statement of a London scientist, whom the Common Council had brought upon the scene—that the arc lights for which 2,000 candle-power was claimed never produced 500 candle-power.

ROYAL SOCIETY.—The following are the new members who have been elected into the Royal Society:—Shelford Bidwell, M.A.; William Colenso, F.L.S.; Harold B. Dixon, F.C.S.; Major-General Edward Robert Festing, R.E.; Andrew Russell Forsyth, M.A.; Prof. A. H. Green, M.A.; Prof. Victor Horsley, F.R.C.S.; Raphael Meldola, F.R.A.S.; Philip H. Pye-Smith, M.D.; Henry Chamberlaine Russell, B.A.; Adam Sedgwick, M.A.; Prof. W. Cawthorne Unwin, B.Sc.; Robert Warington, F.C.S.; Captain William James Lloyd Wharton, R.N.; Henry Wilde.

THE SLATTERY CUT-OUT.—A remarkable test was recently made at the office of the Brush Electric Light Company of Boston with the Slattery cut-out for incandescent lamps in multiple series. The circuit had an E.M.F. of 3,000 volts. The distributor was attached to two multiples of eight lamps each. On turning on or off the ninth lamp (*i.e.*, the first of the second multiple) an automatic switch throws the second set of lamps in or out of series. The inventor removed a lamp and broke the connection of the bare wires without receiving the slightest shock.

THE IMPOSSIBLE.—After the Keely motor, one of the wonders that attract the attention of the American public is the Gray dynamo electric machine. It is claimed that tests have shown that this machine gives enough current for six 2,000 candle-power lamps for one mechanical horse-power. It is further stated that it is the intention of the inventor to utilise this current in suitably constructed electro-motors, and thereby to obtain four or five horse-power from the motors to one horse-power used in driving the dynamo. A portion of the power generated by the motors is utilised in driving the dynamo, it being only necessary to start the dynamo at first by some outside force.

THE ELECTRIC LIGHT AT COLCHESTER.—At a special meeting, held last week, the Colchester Town Council had under consideration the subject of the electric lighting of the borough. It appears that a new company has been formed for taking over the plant and business of the South Eastern (Brush) Electric Light Company, by whom the original electric lighting experiment was carried out in the town. The new company has been incor-

Digitized by Google

porated, but before commencing business it is, of course, necessary that the license granted to the old company by the Board of Trade should be properly transferred to the new one. The Sanitary Committee of the Corporation have already passed a resolution for the extension of the necessary powers to the new company, but the council show some reluctance in ratifying it. The matter is to be further considered.

COMPETITION AND COOL DRINKS.—With the returning summer and increasing severity of competition an enterprising New Jersey chemist, whose store is also a Baltimore and Ohio telegraph office, has renewed the beguiling inducements offered last year by him to persons about to wire, in the following terms:—"Opposition the life of trade. A delicious glass of soda water given away with each telegram sent *vid* B. and O. Telegraph Co. We call the attention of the public to the fact that the B. and O. Telegraph Co. has been the means of bringing low rates and breaking up monopoly. Telegraph with the B. and O. Telegraph Co., save money, and keep cool with a glass of ice cold soda water, given away with each telegram sent *vid* B. and O. Telegraph Co. from the handsome fountain at Van Brunt's Pharmacy, Front-street, Red Bank, N. J."

THE ASTRONOMICAL DAY.—According to the report of the Science and Art Department a number of letters were addressed to the various authorities, in order to obtain their opinions as to the twenty-four hours per day system. A number of replies were received, among which were those from the Eastern Telegraph Company and the Eastern Extension Company, which stated that they have always adopted the twenty-four hours' system in timing their messages, and thus avoided the necessity of signalling the letters "a.m." and "p.m." The Society of Telegraph-Engineers approve the first resolution of the Washington Conference, but reserve their opinion on the one referring to the application of the decimal system to space and time. The Eastern and South African Telegraph Company follows the same system as the Eastern and Eastern Extension. The Submarine Telegraph Company does not adopt the twenty-four hours' system.

NEW YORK TAXES.—In whatever part of the world we may happen to be, the taxgatherer is by no means a pleasant caller, and we have no doubt that many companies would prefer that there were no such things as taxes to be paid. The municipal taxation in New York is 2·4 per cent., and the amount of taxes levied upon electrical interests in the city amounts to over 38,000 dollars. The largest payment seems to be that of the Metropolitan Telephone and Telegraph Company, a little over 6,398 dollars. The United States Electric Lighting Company pays some 5,889 dollars, the Edison Electric Illuminating Company running them close with 5,223 dollars, while the Edison Lighting Company pays 3,824 dollars. The British Electric Illuminating Company pays 1,824 dollars. The Western Union Telegraph Company pays 2,232 dollars. Several other companies pay over 1,000, and the last and the least is the American Speaking Telephone Company and the Equitable Electric Company running a dead heat, each paying 4 dollars 80 cents.

THE GOOLDEN AND TROTTER DYNAMO.—It is not often that three independent individuals hit upon the same idea almost simultaneously. A new type of dynamo, so far as the arrangement of the magnets is concerned, has been introduced by Messrs. Goolden and Trotter. A very similar pattern has been recently produced by Mr. Kapp, and it appears that an American inventor is working on the same lines. The dynamo may be described as having an Edison field, in which the yoke as well as the bars are wound. A number of these have been mounted with Messrs. Heenan and Froude's tower spherical engine, for use on the sea-going torpedo boats, the combination being probably the smallest for its weight, speed, and output that has ever been produced. The dimensions over all are—Height, 2ft. 3in.; length, 3ft. 6in.; width, 1ft. 6in.; weight, with bedplate, lubricators, &c., 8 cwt. The output is 60 amperes, 60 volts, 650 revolutions at 90lbs. steam. The engine and dynamo are easily capable of producing 4,000 watts at 700 revolutions.

FRENCH PRIZE COMPETITION.—Among the subjects put down for the prize competition for the year 1887 by the Société d'Encouragement we note the following, which are of peculiar interest to those of our readers who are of an inventive turn of mind:—A prize of 2,000fr. for a small motor designed for a family workshop to be worked separately or to be connected with a central factory. A prize of 3,000fr. for a medium of transporting to a considerable distance natural mechanical powers which their actual position does not allow of being immediately utilised. A prize of 3,000fr. for the invention of a simple and substantial appliance capable of indicating automatically in a sure and regular manner at a given distance the speed of a railway train. A prize of 3,000fr. for the construction of an instrument for transmitting to a distance an indication of the temperature of a heated enclosure. A prize of 3,000fr. for the discovery of a perfect process of transmitting to a distance motive power to agricultural machines. Competitors must send in their contributions before the 1st of January next.

THE "COMMERCIAL CABLE."—The following is the letter referred to in our leader:—"We respectfully tender our thanks to those of our friends and customers who have notified us of their intention to support the Commercial Cable Company during the impending tariff contest. The very large number of communications which we have already received renders it impracticable for us to make separate acknowledgment to each. We trust, therefore, that all will accept this public announcement of our appreciation of the large and cordial support thus assured to us in advance. A few of our friends have asked us what assurance of protection we can offer to them in case the patronage extended should not be sufficient to enable us to withstand the attack now made upon the company. Recognising the propriety of such inquiry, we now announce that in the event of our being compelled to advance our rates *beyond those which we have heretofore charged*—40 cents per word—we will refund the amount of excess that may have been paid to us during the continuance of the struggle, viz., the difference between 12 and 25 cents per word between America and Great Britain and France, and the difference between 15 and 25 cents between America and Germany."

METEOROLOGICAL.—The great interest in meteorological observation and weather prediction which has been fostered by the Signal Service Bureau is well illustrated by the proposed action of the New England Meteorological Society. The latter, says the *Electrical World*, aided by numerous volunteers, to the number of 300, has determined to make a close study of thunderstorms during the three months beginning June 1st. A special feature of the work is found in the appointment, in advance of certain days, to be called term days, on which thunderstorms may be expected in some parts of New England, and on which all observers are to make certain systematic records. These term days will be appointed by the Signal Office in Washington, and the announcement of them will be sent by telegraph to all newspapers in New England belonging to

Digitized by Google

the Associated Press or the United Press. An extended publication will thus be secured, and the appointments will be brought to the notice of all observers. Such systematic study by numerous observers, widely scattered, cannot fail to establish results of the greatest value. The science of meteorology, and weather prediction especially, has been greatly developed in this country, and the benefits derived therefrom are becoming more and more manifest.

TELEPHONE EXTENSION.—We understand that within the next fortnight the Western Counties and South Wales Telephone Company will open their Telephone Exchange in Swansea, having secured convenient premises at the bottom of Wind-street in proximity to the docks and merchants' offices. In addition to the network of wires which will be gathered into and ramify from the new Swansea Exchange for the accommodation of the local business which is likely to speedily accrue upon the extension of this great convenience of modern life, there will be direct communication with Llanelly at once, and within a short time the new company's wires will extend to Landore, Neath, Aberdare, and thence through Newport, we believe, to Bristol. Mr. H. F. Lewis, the general manager and secretary of the company, has been in Swansea during the present week perfecting arrangements. The directorate, as we have previously had occasion to notice, is a very influential one, including some of the leading commercial men of Bristol and Cardiff. The Swansea Commercial Exchange is intended to be open both night and day, Sundays excepted. The convenience of having electrical communication with an exchange, and through it with the police and the hospital at night, and with numerous business firms by day, is so apparent, that within measurable time every considerable house will be so connected.

SOCIETY OF ARTS.—The Council of the Society of Arts have awarded the society's silver medal to the following readers of papers during the session 1885-86:—To Prof. Francis Elgar, LL.D., for his paper on the load-lines of ships; to Henry Davey, for his paper on machinery in mines; to Prof. W. C. Unwin, for his paper on the employment of autographic records in testing materials; to C. V. Boys, for his paper on calculating machines; to Prof. Leonard Waldo, D.Sc, for his paper on watch-making by machinery; to John Mackenzie, for his paper on Bechuanaland and Austral Africa; to Edward Combes, C.M.G., for his paper on the industries and commerce of New South Wales; to G. Gordon Hake, for his paper on Cyprus since the British occupation; to Prof. W. N. Hartley, F.R.S., for his paper on photography and the spectroscope in their application to chemical analysis; to Prof. R. Meldola, for his paper on the scientific development of the coal-tar colour industry; to B. H. Baden Powell, C.I.E., for his paper on Indian manufactures from a practical point of view; to Capt. Richard Carnac Temple, for his paper on the every-day life of Indian women. Thanks were voted to the following members of the Council for the papers read by them:—To Capt. Douglas Galton, D.C.L., C.B., F.R.S., for his paper on results of experiments on mechanical motors for tramways made by the Commission at the Antwerp Exhibition; to W. H. Preece, F.R.S., for his paper on domestic electric lighting.

FOREIGN TELEGRAMS.—On and from the 1st prox. the new regulations respecting foreign telegrams agreed upon at the International Telegraph Conference held at Berlin will come into force. The principal alterations are the following:—(*a*) The rules relating to European have been assimilated to those relating to extra-European code telegrams, the limit of length of a word in such messages being fixed at ten letters, and words drawn from more than one of the authorised languages, viz., English, French, German, Italian, Dutch, Portuguese, Spanish, and Latin being allowed; (*b*) the names of both the office and the country of destination will be counted in the address as one word each, whatever their length, provided they are written as single words by the sender, and are spelt in accordance with the official list; (*c*) the sender of a telegram will be able to have it repeated from office to office during transmission by paying an additional quarter-rate instead of a half-rate as at present; (*d*) if the sender of a European telegram prepays a reply, and the reply form is not used by the addressee, the amount prepaid for a reply will not be refunded as hitherto; (*e*) if the addressee of a telegram has it repeated and it then proves that only a portion of the telegram was inaccurately transmitted, only a proportionate part of the charge will be refunded; (*f*) the charge for any word or words omitted during the transmission of an extra-European telegram will be refunded; (*g*) the rates to several countries will be reduced, as may be seen on reference to the "Post Office Guide" for July. The following are a few examples:—Russia, from 9d. to 6½d.; Spain, from 6d. to 4½d.; Italy, from 5d. to 4½d.; India, from 4s. 7d. to 4s.

ATMOSPHERIC ELECTRICITY.—The following is an abstract of a paper by Prof. Franz Exner in the *Philosophical Magazine*. It says:—"After a critical historical discussion of previous theories, the author communicates the results of his experiments on this subject, which have extended over several years. They refer chiefly to an examination of the electrical field of the earth under *normal* atmospheric conditions. It has appeared that the equipotential surfaces are continually as if the earth had a negative charge. Over a plane the fall of potential is always linear, and its absolute value is constant if the condition of the atmosphere does not change. Such changes are due to the greater or less quantity of aqueous vapour in the air, for this leaves the earth charged with negative electricity. The greatest fall of potential amounts to 600 volts per metre in the complete absence of aqueous vapour, and sinks to below 100 volts in the height of summer. These numbers hold, however, only for continuous fine weather. A measurement of the fall of potential in summer at great heights, by means of air-balloons, has proved that this increases considerably with the height; that is, that aqueous vapour in air is really negative. All the phenomena of negative electricity are completely explained on the assumption already made by Peltier that the earth contains a negative charge. Starting from Franklin's theory, this charge appears as a necessary consequence of the gradual formation of the earth, and would correspond to an excess of electricity above the normal amount. Bodies which are in the condition last named would thus appear negatively electrified. From the magnitude of the fall of potential at the surface of the earth, the absolute potential of the earth may be determined. This is found to be $= -4 \cdot 10^9$ volt; that is to say, a point in space which is infinitely distant from all electrical masses has a potential which is $4 \cdot 10^9$ volts higher than that of the earth. The repulsive force which is exerted by the charge of the earth on a square centimetre of surface is equal to $16 \cdot 10^{-9}$ grams, and is thus extremely small.

ELECTRIC LIGHT IN PARIS.—The administration of the Opera Theatre have come to a decision which is the best testimony that they could give to the efficiency of the Edison incandescent lamp. After putting to the test, during a period of about four months, the electric light in the auditorium, the lobbies, and the grand staircase, and having thoroughly satisfied themselves as to the quality of the light, they have made a contract with the Edison Company for lighting the

Digitized by Google

entire building with electricity. The new installation, which in size will be double that already in operation, will increase the number of lamps in the opera to 6,126, of which 5,018 will be of 10 candle-power, and 1,108 of 16 candle-power. These lamps will replace 7,570 jets of gas, and will be distributed as follows :—

Offices	1,160	of 10 c.-p. and	40	of 16 c.-p.
Stage	1,568	„	120	„
Auditorium and pavilion	1,212	„	306	„
Lobbies and staircase	1,010	„	642	„
Cellars	68	„	—	
	5,018	of 10 and	1,108	of 16.

Gas will thus be entirely done away with, and the whole of the opera house will be lighted by incandescent safety lamps, of the kind required by the Prefecture of Police. This step is the more important as it has been taken conjointly by the State and the directorate of the theatre. The contract entered into with the Edison Company is made for a period of ten years. The light will be furnished by the company for a sum equal to the average outlay for gas during the last ten years. Supplementary lighting, such as that for balls, rehearsals, &c., will, of course, be paid for extra. In the face of such a triumph for the electric light, it is beyond question that we are fast approaching the time when all places of amusement in the French capital will be illuminated by electricity. As we pointed out last week, the subject is engrossing the attention of the directors of many of these establishments, for they are beginning to perceive that gas as an illuminant has had its day.

Germanium.—M. Lecoq de Boisbandrin, when he discovered a new metal some years ago, gave it the significant name of gallium. We have recently become indebted, says the *Revue Industrielle*, to the Germans for germanium. This substance has been found in an argentiferous mineral, met with in the mine of Himmelfuerst, near Freiberg. This mineral was called argyrodite by Prof. A. Weisbach on account of its appearance, and was examined at the blow-pipe by M. T. Richter, who showed that it consisted principally of silver and sulphur together with a small quantity of mercury. More complete analyses fixed the proportion of silver at 73 to 75 per cent., that of sulphur at 17 to 18, with 0·21 per cent. of mercury, a little iron, and some traces of arsenic. But about 6 or 7 per cent. always escaped the ordinary methods of qualitative analysis. This was something to excite the curiosity of a chemist, and although the research was rather tedious, M. C. Winkler set to work to determine the exact composition of this rock. He was thus led to establish the existence of a new element, much resembling antimony, but still very distinct. This was germanium, which is distinguished by the following reactions: Argyrodite heated out of contact with air, preferably in a current of hydrogen, gives a black, crystalline, very volatile sublimate, capable of being melted into drops of reddish brown, and principally composed of sulphide of mercury and germanium. The sulphide of germanium is a sulphacid, easily soluble in sulphydrate of ammonia, and giving when precipitated by pure hydrochloric acid a snow-white powder, which is immediately dissolved by ammonia. In the presence of antimony or arsenic the precipitate is always more or less tinted with yellow. Heated in a current of air or in nitric acid the sulphide of germanium is converted into a white oxide, which does not volatilise even at a red heat. It dissolves in caustic potash, and the alkaline solution, when treated with sulphurretted hydrogen, reproduces the white precipitate, more or less quickly according to the degree of concentration of the liquid. The oxide, like the sulphide, is reduced by hydrogen, and yields a grey substance, slightly lustrous like arsenic, volatilisable at a white-red heat, but less easily than antimony. In this operation it sublimes on the glass walls in crystals which have the appearance of sublimated iodine, without any indication of fusing, and cannot be taken for antimony. With a current of gaseous chlorine a white chloride is obtained more readily volatilised than the chloride of antimony. Dissolved in water and treated with sulphuretted hydrogen the white precipitate is reproduced. From the whole of these facts the existence of germanium seems to have been determined. There still remains to fix its atomic weight with a certain amount of exactness, in order to know whether it ought to take the place reserved by the theory of Mendéléeff between antimony and bismuth.

Polarisation of Lead.—A preliminary series of experiments by F. Streintz and E. Aulinger was made by Fuchs's method to determine what share the hydrogen evolved at the negative electrode has in the value of the polarisation. The lead plates were in a vessel containing a 10 per cent. solution of sulphuric acid, and were charged from a battery of three Daniell cells; by means of a capillary syphon tube this vessel communicated with a second one in which was a zinc plate in concentrated solution of sulphate of zinc. The lead plate at which the hydrogen was evolved was in connection with one pair of quadrants of an Edelmann's electrometer, and with earth, the zinc plate being connected to the second pair of quadrants. The standard of comparison was a Latimer Clark cell giving 1·433 volt at 15·5° C. Half an hour after closing the circuit of the charging battery, the difference of potential Zn | Pb + H was − 0·26 volt, which rose to 0·29 volt in an hour, and became 0 45 volt on opening the circuit of the charging battery. This last value was maintained for some time, and it was only after several hours that it reached 0·75 volt, the difference previously found for Zn | Pb. This behaviour of the lead plate may be explained by the assumption that it is only so long as nascent hydrogen is evolved that it causes a polarisation, and when the evolution of gas ceases the polarisation ceases. A different mode of operating was then adopted, by means of which the potential of either lead plate could be compared with that of a zinc plate in sulphate of zinc by means of an electrometer, at the same time that the discharge current was measured on a galvanometer. From the tables of results it is apparent that the E.M.F. almost immediately attains a value which approximates to that between metallically clean lead and zinc. The difference of potential between the zinc and the lead plate at which hydrogen is evolved increases slowly during the first three minutes that they are connected to the electrometer, and rapidly during the fourth minute, soon after which there is a sudden jump to a much higher value, which afterwards only increases very slowly. The value of the current meantime decreases proportionately to the increase of the E.M.F. The behaviour of the plate covered with peroxide is very different; at the very beginning its potential, compared with zinc, is very much higher than that of the other plate, and only diminishes by about $\frac{1}{10}$th volt in the first half minute, after which it remains practically unaltered. From the experiments it may be concluded that just as the lead plate covered with peroxide is the carrier of the chief E.M.F., so the plate covered with hydrogen is the source of its falling off. The discharge of the couple is not due to the de-oxidation of the peroxide plate, but to the oxidation of the metallic plate. Whilst, therefore, the hydrogen evolved on the depolarisation does not suffice to reduce the whole of the peroxide of the one plate, the oxygen evolved is sufficient to cover the metallic plate with a layer of oxide, or even of peroxide.—*Jour. Soc. Tel. Eng.*

THERMO-ELECTRICITY.—Although many combinations of conductors producing a greater or less E.M.F. under the influence of heat have already been described, the search for bodies which possess this property has acquired a great interest on account of their possible application to thermo-electric generators. M. G. Chaperon has, according to the *Revue Industrielle*, methodically studied from this point of view a certain number of chemical compounds, chiefly chosen amongst those which can be easily reproduced in their active state. The method employed in this research is characterised by being applicable to fragments of any form whatever, and, if need be, of very small dimensions. It consists in applying two points of one of these fragments to two metallic walls, which conduct heat well, whose temperatures are evaluated as closely as possible, and which serve as electrodes to show and measure the E.M.F. of the couple thus formed. One of these walls is that of a thin silver tube traversed by a current of water at the temperature of the surrounding air, and forming part of a pair of pincers with which the body under consideration is held. By means of these pincers a second point of the body is applied against a hot wall, that of an iron crucible full of fusible alloy, and into which a thermometer is plunged. Contact ought to be insured by a constant pressure. The procedure is then to measure during slow variations of temperature a series of values of the difference of potential of the two plates. The iron crucible is united to the electrical measuring apparatus by a silver wire sufficiently long for its extremity to remain cold. The E.M.F. measured is then, in virtue of the law of successive contacts, that of the couple formed by the body which is under investigation and silver. For certain compounds capable of attacking iron a thin leaf of silver is also interposed at their point of contact with the crucible. For more elevated temperatures another arrangement has also been employed, in which the hot contact is taken at a point of a silvered copper bar heated at one extremity. The temperature is evaluated at another point of the same section of this bar with a second body already studied, and which thus serves as thermometer. In the various couples thus formed the contacts of active substances with the electrodes ought to take place by small surfaces, which are as distant from one another as possible, in order that the temperatures of these contacts may be as nearly as possible those of the electrodes, which alone can be estimated. One thus obtains with substances in general bad conductors elements of an enormous resistance; therefore the rapid measurement of the E.M.F.'s is only rendered practically possible by the use of Lippmann's electrometer. Besides, this only serves to show the equilibrium of the force measured with that given by a potentiometer with wire of a reduced form giving $\frac{1}{5000}$th of a volt. It is possible with this conjoint apparatus to obtain sufficiently easily curves representing the law of variation of the E.M.F.'s as functions of the fall of temperature. M. G. Chaperon then quotes some examples of measures thus made on substances little studied and enumerated below. Positive bodies: iodide of silver, phosphide of zinc, sulphide of tin, crystallised galena, oxide of copper in a very thin plate, arsenide of zinc. Negative bodies: sulphide of silver, specular iron, crystallised galena. The curves representing the force as a function of the fall of temperature indicate in general a uniform increase starting from a certain point; they have been followed up to 250 or 300 degrees. Nevertheless, for the iodide, and, above all, for the sulphide of silver, the law of variation undergoes a sudden change, and hardly appears susceptible of being represented by a continuous function.

TELEPHONIC STATISTICS.—The following is a continuation from our last issue of M. Rothen's telephonic statistics:—

The Argentine Republic.

Towns.	No. of Subscribers.	Population	Population per Subscriber.	Subscription in Francs.
Buenos Ayres...	1,544	340,000	220	450

This information is brought up to 18th October, 1885. The exchange is worked by the River Plate Telephone and Electric Light Company.

Uruguay.

Montevideo	389	111,500	287	240

This information is brought up to 18th October, 1885. The exchange is worked by the River Plate Telephone and Electric Light Company.

The Sandwich Islands.

Honolulu	425	14,114	33	—
Other towns ...	600	—	—	—

The exchanges are worked by the Havaian Telephone Company.

India and Ceylon.

Calcutta (*a*)	336	794,645	2,365	710
Bombay (*b*)	281	645,000	2,295	710
Rangoon (*c*)	109	97,000	906	710
Maurice (*c*)	76	64,000	842	—

Townsville	51	3,000	59	—
Rockhampton ...	45	7,431	165	—

Mid-Australia.

Adelaide	529	27,300	52	—
Port Adelaide ...	46	2,481	54	—

This information is brought up to the month of May, 1884. The telephone exchanges are worked by the Government. The total length of the wires of the two exchanges is 1,572 kilometres. The subscription is 300fr. for a maximum distance of 800 metres, additional distances being paid for at the rate of 32fr. 50c. per 400 metres. For the right to converse between Adelaide and Port Adelaide subscribers pay an additional annual charge of 250fr. The transmission and receipt of telegrams are charged at the additional rate of 30 centimes per despatch. The service is permanent at Aelaide.

New South Wales.

Sydney	260	224,211	862	—

This information is brought up to the month of May, 1884. The exchange belongs to the Government. The subscriber pays for his line and its appointments, and in addition an annual subscription of 125fr. for a distance of 1,600 metres. Every additional 400 metres pays a supplementary charge of 32fr. 50 centimes.

Victoria.

Melbourne	716	282,947	395	—
Ballarat	81	35,586	439	—
Sandhurst	37	28,167	761	—

This information is brought up to May, 1884. The exchanges are worked by the Melbourne and Colonial Telephone Exchange Company, but the Government also establish some private communications.

EARTH CONDUCTION.

BY A. J. S. ADAMS.

The future prospects of telephony and practical telegraphy would seem to be somewhat in the dark; but it is nevertheless unwise to discount the possibilities of such systems until we are possessed of a more exhaustive knowledge of the physical forces that are brought into play. Each successive step in elimination and elucidation is found to advance the general subject; and remembering how little is really known regarding some phenomena connected with electricity and magnetism, the surprise is that so much has been accomplished, and that there exists to-day such solid ground for congratulation and encouragement.

Our want of knowledge in respect to the telephone may be instanced by the several theories that have been advanced to explain the precise action of the telephone, and the remaining fact that no theory has yet proved to be incontrovertible, or to greatly modify our earlier conceptions. In respect to line conduction, our imperfect knowledge has been rendered conspicuous by the recent labours of Prof. Hughes, and by the experiments of Mr. W. H. Preece, and there is in connection with this point much yet to be learned. It is possible, however, to go farther, and show that our need of information obtains not only in respect to the apparatus and to the line, but also in relation to the earth—where the earth's crust forms part of the circuit—and that the earth then exerts no inconsiderable effect upon the general result. In connection with this point it will be admitted that a telephone circuit, of which the earth forms a part, is never so satisfactory as it is where the circuit is wholly metallic, a feature clearly indicated in the interesting paper lately contributed to the Society of Telegraph-Engineers and Electricians by Mr. Preece, although it must be confessed the difference remains unexplained. Again, as regards the question of earth conduction, it may be remembered that in 1875 Mr. James Graves, of Valentia, contributed to the society already referred to an important communication upon "variations due to earth-plates," and detailed the extraordinary difficulties that were experienced by him in reading from the mirrors attached to the Atlantic cables, by reason of variations and disturbances which produced a constantly irregular motion of the "spot."

A brief consideration of this phenomenon may not be out of place at the present time, and possibly it may be gathered from the results of some experiments that have been made that the disturbance complained of by Mr. Graves possesses a marked and distinctive character, and, first, as to the probable resistance introduced into a circuit by the earth's crust. The earth cannot be considered as a conductor of electricity, apart from the moisture held by it; it is evident, indeed, that the earth's capacity for conduction will be to a large extent proportional to the moisture so held. When, however, the wide expanse of moist earth that almost necessarily divides two earth-plates is considered, it is difficult to apprehend any appreciable resistance to exist between them; and yet that some resistance is offered by the earth will appear from the following experiments:—Two clean copper plates, about 18in. square, were buried 20ft. apart to a depth of 4ft. in a soil of loam, overlying sandy gravel. The earth plate electrolysis current steadily fell from first maximum to a point at which it was very weak, and then remained constant. Across and midway between the two plates shallow trenches were dug, and were kept supplied with water for some hours, the ultimate result being that, by reason apparently of the diffusion of moisture and the reduction of resistance, the current force increased several degrees.

The apparatus used was a sensitive Thomson reflecting galvanometer of 700 ohms resistance, and the scale was twenty-seven feet distant from the galvanometer, so that a very slight variation of force in the galvanometer would be well represented by the movements of the "spot." In the further experiment two flat coils of No. 18 copper wire were buried upright about 18in. below the surface, and 4ft. apart. The electrolysis current at first equalled a deflection of 38in. upon the scale, but after falling steadily came to a stand at 18in. from zero, and remained constant. The ground over and around these upright coils was now thoroughly soaked with water, and two days were allowed for diffusion. A trench was then dug of the same dimensions either way as the coils, between and parallel to them; the trench was a foot wide at top and tapered at the bottom. The effect of this trench was to decrease the deflection by 8in. A small piece of dry board was ledged across the trench at its centre, and a child was instructed to build a bridge or road of damp earth from side to side over the board. The instant contact was made by the damp earth across the board, the deflection went up with a bound, and every succeeding reduction of resistance by the addition of earth to the bridge was clearly visible in the movement of the "spot." By this bridge the deflection was permanently increased by three inches, but again fell off as the earthen bridge dried under the sun. The effect of filling in the trench was also rendered clearly apparent by the swinging of the "spot" and ultimate increase.

It would thus seem that the earth's crust presents a higher resistance to the passage of electricity than would at first sight appear; secondly, and perhaps of greater moment, as to the apparent variability of the earth's conduction. Reference has been made to difficulties experienced at Valentia in reading the mirror signals received from America, by reason of irregular variations of the "spot," and which seemed to emanate from the earth plate. In that instance the disturbances could not be eliminated until *earth* was virtually made by means of the sheathing of the Atlantic cables, instead of by the ordinary earth plate method. It may be stated that precisely similar variations are to be observed upon any circuit of which the earth's crust forms a part, provided that the means of observation are sufficiently sensitive, and that the wire tested is free from the larger effects of leakage, induction, and earth current.

Perhaps the most natural explanation that suggests itself concerning these variations is that of earth-plate variation—*i.e.*, a variation of the actual force generated at the plates, or of their resistance. In order to investigate the phenomenon from that point of view, the sensitive Thomson reflecting galvanometer was brought into use, and tests were made of a great number of combinations—simple and involved, new cells and old, pairs of similar and dissimilar metals—without once obtaining the slightest sign of the variation in question. In every case there was the usual electrolysis current, which steadily fell from a first deflection to a stationary minimum, and which by disconnecting the circuit, or by inserting heavy resistance, would temporarily increase; but nothing beyond that was noticeable. It was thought that in the case of an earth plate the deposited hydrogen might by some means be disturbed, and so vary the resultant force. To test this point the following experiment was made:—The ends of two clean copper wires were immersed in a jar of sand and water; in the centre of this cell was inserted a 1¼in. glass tube, 3ft. high, so that by keeping the tube filled with water there would be a circulation of the liquid up through the sand and around the wires, the idea being to effect a disturbance of hydrogen. No visible effect was produced, however, and it seemed clear the variation in point was not of simple earth-plate causation.

Another possible explanation of these variations suggested itself, namely, that the influence of slight earth currents upon the earth plates might produce an intermittent and changing state of polarisation. In order to investigate this point a No. 18 copper wire was erected and perfectly insulated, and extended from my house to a distance of 300 yards upon one side, and of 170 yards upon the other. The distant ends were terminated by means of large coils of the same wire, buried to a depth of about 6ft. In my own garden similar *earths* were put in for us as might be required. With the Thomson reflecting galvanometer in circuit, whether upon the whole length of line, or upon the right or left sections, it was always necessary to shunt down the electrolysis current in order to bring the "spot" within the ten foot scale, and notwithstanding this reduction of current passing through the galvanometer coils, the variations under consideration were always present. This variation, this *constant* movement of the spot, was usually much greater in amplitude

Digitized by Google

upon the 300 yards length than upon the 170 yards section. Why it was difficult to trace, but it may be added that a baker's oven, which was heated each day, lay directly in the line of the two *earths* of that section. Then, also, the amplitude of the variation altered very considerably one day with another, sometimes the swing of the "spot" being so much as eight feet from side to side, *i.e.*, four feet each side the zero. It was difficult to decide how the question of earth current causation should be attacked; the first experiment, however, afforded no trace of concurrency in the variations of the two sections of wire.

A further experiment was conducted with a view to question the effect of earth-current *directive* force upon the earth plates, and was arranged thus:—A circle 40ft. in diameter was described, and the chief points of the compass carefully staked upon it. Two poles were sheathed with clean copper at their lower extremity, the copper being connected to the experimenting room by means of loose-covered wires. The sheathed ends of the poles were driven into the moist earth to a depth of two feet. Starting with the poles at opposite points —N and S—upon the circle a careful observation was made, and the slight but clearly discernible oscillations of the "spot" were noted. Similar observations were repeatedly made with the poles at each pair of opposite points, but without leading to any trace of directive effect, both variation and amplitude being pretty much the same all round the circle, and the idea of earth-current connection was, for the time being, given up. The fact had, however, been elicited that these variations were in a slight degree obtainable from *earths* that were comparatively near one another, although when very near the effect upon the apparatus ceased. Prior to dismantling the arrangement the following experiment was tried:—Two pairs of earth plates were buried thirty feet apart, the respective plates of each pair being three feet apart. Upon joining either pair through the galvanometer no variation effect was observable, but when either plate of one pair was joined through the galvanometer to either plate of the other pair slight oscillations of the spot became apparent, indicating, it would seem, that at least some extent of the earth crust between a pair of earth plates is necessary in order to obtain these effects.

The remarks submitted here are not intended as a solution of this phenomenon, for it will be apparent that many important experiments await trial; but it is thought that the importance of the subject in its relation to long-distance telephony, and to the more sensitive systems of telegraphy, is such as to deserve a larger share of attention than it has hitherto received, and, further, that these results, which seem to point to a variation in the conducting power of the earth itself—locally, perhaps—warrant a more thorough and continued course of investigation than is within my own reach. It would be of interest also to know if and how far this variation is related to the sound disturbances heard from a buried microphone.

INDUCTION IN CONDUCTORS.*

The law of Ohm is only true when the current has become constant. In the greater number of cases we have to consider variable currents. Dynamo machines, whose usage is so widespread, furnish currents essentially variable. The variations are evident in machines with alternate currents. They are less so in machines, improperly called of constant currents, in which the telephone, nevertheless, reveals rapid changes of intensity. Those who have a telephonic wire near a wire traversed by currents called continuous, may soon disagreeably perceive that these currents do not merit their reputation. It is a curious thing that the currents of alternating machines, in which the variations of intensity are slower than in other machines, have a less hurtful influence on the telephone. They give a deep hum, which does not mask the sound of the voice like the sharp crackling given by machines with continuous currents.

Batteries and accumulators are capable of giving permanent currents, on the condition that their circuit has been closed sufficiently long.

Let us consider, not otherwise, a circuit formed by a battery, a subterranean line, and the earth.

At the moment of closing the circuit the cable charges itself, and during the whole duration of this phenomenon the current varies. It does not attain the stable state till after a shorter or longer time (several seconds in Atlantic cables). It is only after this delay that the law of Ohm is applicable to the calculation of the intensity of the current.

The amount of the charge is extremely small on aerial lines, and it may be neglected on short ones.

Consider, now, another class of phenomena. Suppose that a telegraphic line is parallel to a telephonic line. At the moment of making the telegraphic circuit, an inverse induction current traverses the telephonic circuit, and a direct one when the telegraphic circuit is broken. The induced current depends on the coefficient of mutual induction between the two wires. If l is the length along which the two wires are parallel, h their distance apart, this coefficient is approximately expressed by

$$M = 2l\left\{\log\left(\frac{2l}{h}\right) - 1\right\}$$

The phenomenon of induction arises also in the circuit itself where the current forms, and then it is called self-induction. Let us consider the case where a current arises in a coil of wire. At the moment of closing the circuit the coils react on one another, and an electromotive force of induction is produced, which tends to weaken the inducing current. Similarly, when the circuit is broken we have a direct induced or "extra" current. The self-induction of a current depends on the form of the circuit, and practically the current usually reaches its full strength in a very short time indeed. Nevertheless in telegraphic systems, where they employ very rapid mechanical keys, the currents may not reach the permanent state.

Let us take the case where the E.M.F., instead of being constant like that of a battery, varies in accordance with a given law. This is the case of a machine with alternating currents, where the E.M.F. may be expressed at each instant by

$$E = E_0 \sin\frac{2\pi t}{T}$$

Such an equation is represented graphically by a sinusoide, the abscissæ denoting time and ordinates the corresponding values of E. E_0 is the maximum value of E, T the space of time which elapses between two like indulations of the curve.

The E.M.F. which produces telephonic currents may be defined by an analogous law of variation; but, while the values of T vary between $\frac{1}{80}$th and $\frac{1}{120}$th of a second for ordinary alternating machines, they vary between $\frac{1}{300}$th and $\frac{1}{2000}$th of a second for telephones.

If there was no self-induction in the circuit where the periodic E.M.F. acts, the intensity of the current would be expressed by

$$i = \frac{E}{R} = \frac{E_0}{R}\sin\frac{2\pi t}{T}$$

The phases of the current would coincide with those of the E.M.F.

In the case where the circuit has a co-efficient of self-induction L, the intensity at each instant is

$$i = \frac{E_0}{\sqrt{R^2 + \frac{4\pi^2 L^2}{T^2}}}\sin\left(\frac{2\pi t}{T} - \phi\right)$$

where ϕ is given by the equation $\tan 2\pi\phi = \frac{2\pi L}{T}$.

The effect of the phenomenon of self-induction is to produce a retardation in the undulations of the current and to diminish the intensity as if the resistance had increased in the ratio of $\sqrt{R^2 + \frac{4\pi^2 L^2}{T^2}}$ to R.

The quantity under the root sign represents the apparent resistance of the circuit, and this may become much greater than the actual resistance.

* From a paper by Prof. Eric Gerard, in the *Bulletin de la Societe Belge des Electriciens*.

Digitized by Google

Let us suppose, for example, that a telephonic current, whose period is $\frac{1}{1000}$, traverses a coil, whose resistance is 50 ohms, and whose coefficient of self-induction is 0·6. Then the value of $\sqrt{R^2 \tau \frac{4\pi^2 L^2}{T^2}}$ is about 4,000, or 80 times the resistance of the coil.

It has been long known that the phenomena of self-induction are not well marked, except in conductors rolled up in the form of coils. Nevertheless experiment has shown that a rectilinear wire sufficiently long may become the seat of an extra current capable of producing a spark. Kirchhoff and F. Weber have given expressions for the coefficient of self-induction in rectilinear wires; but this phenomenon was little studied till the recent experiments of Prof. Hughes have drawn the attention of electricians to it.

Let us consider a rectilinear conductor of circular cross-section in which a current originates. This may be resolved into an infinite number of infinitely small currents passing parallel along the wire. All these small elementary currents react one upon another so as to give rise to an inductive E.M.F. contrary to that which produces the current. The coefficient of induction in the case of two rectilinear parallel currents is as we have seen

$$2l\left\{\log\left(\frac{2l}{h}\right)-1\right\}$$

Now, the mean distance of all the elementary currents traversing a circular section of radius r is

$$h = 0{\cdot}7788r,$$

whence we conclude that the coefficient of self-induction of a like conductor is

$$L = 2l\left\{\log\left(\frac{2l}{r}\right)-0{\cdot}75\right\} \quad \ldots \quad (1)$$

The phenomenon of self-induction is much more marked in a magnetic conductor, such as an iron or steel wire. Every time that a current arises in the wire the exterior layers of the conductor are magnetised in a direction perpendicular to that of the current, whence there results a circular magnetisation. This magnetisation absorbs a part of the energy of the current and weakens it. When the current ceases, the magnetisation disappears and the energy reappears under the form of extra-current.

The coefficient of self-induction of a magnetic wire contains a constant depending on the magnetisability

$$L = 2l\left\{\log\left(\frac{2l}{r}\right)-0{\cdot}75+k\right\} \quad \ldots \quad (2)$$

Telegraph engineers had long remarked that copper conductors are more favourable than iron conductors with apparatus for rapid transmission.

The importance of this observation has been placed in a clear light in consequence of the experiments of Prof. Hughes.

These experiments and their results are well known. They have been criticised by Prof. F. Weber and others, who have concluded that the differences observed by Hughes in the case of non-magnetic bodies arose from particular conditions of the experiments.

For our part, we have studied a method which is more easily discussed than that of Prof. Hughes, and of which the following is a description.

The conductors to be compared, M N and M′ N′ (Fig. 1), form a circuit with a battery P, an interrupting wheel R, and a rectangular movable frame covered with wire. The auxiliary wires $f_1 f_2$ and $f_1' f_2'$, situated in a plane normal to that of the principal circuit, may be united either to the two coils G_1 and G_2 of a differential galvanometer, or to some coils T_1 and T_2, belonging to a differential telephonic arrangement. A revolution of the commutators enables the transposition to be made rapidly.

Suppose that communication is established with the differential galvanometer, and that the principal circuit is traversed by a permanent current. The galvanometer needle will deviate as long as the resistance $a\,b$, contained between the auxiliary wires $f_1 f_2$, is not equal to $a'\,b'$, the points of junction of the wires $f_1' f_2'$.

The positions of the riders must be regulated to satisfy the conditions of equilibrium. If we call each of the two equal resistances r, I the intensity of current, the difference of potential between the points $a\,b$, or $a'\,b'$, will be $E = Ir$.

Next let us unite the auxiliary wires to $T_1\,T_2$, and let us set the interrupting wheel in motion, so as to produce intermittent currents in the principal circuit. T_1 and T_2 are as nearly alike as possible in all respects, and the variable currents which branch into the two coils T_1 and T_2 act in opposite senses on a third coil T_3 united to a telephone.

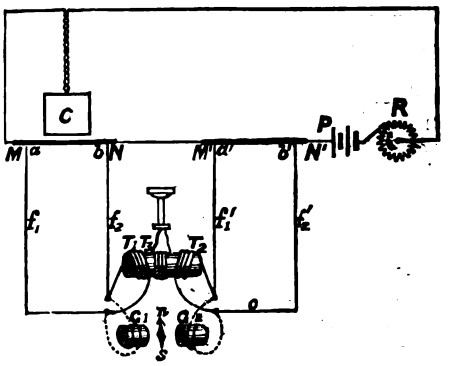

FIG. 1.

One commences by regulating the position of this coil T_3, so that the telephone gives no sound when $f_1 f_1'$ and $f_2 f_2'$ are united to the same two points of the principal circuit—that is to say, when the extremities of the coils $T_1\,T_2$ remain constantly at the same difference of potential.

This being the case, the difference of potential between a' and b' is at any instant

$$e = ri + L\frac{di}{dt}$$

L being the coefficient of self-induction of the section $a'\,b'$.

The difference of potential between the points $a\,b$ is

$$e' = ri + L'\frac{di}{dt} + M\frac{di}{dt}$$

L′ is the coefficient of self-induction of $a\,b$, M is the coefficient of mutual induction between the frame C and the conductor $a\,b$. The position of the frame C is regulated by bringing it closer to, or moving it farther from, the conductor $a\,b$, till the telephone gives no sound, which happens when M equals the difference of L and L′. When this is the case, the E.M.F.'s in $a\,b$ and $a'\,b'$ are always equal; then we have $e = e'$, whence

$$L = L' + M$$

Now M may be easily calculated. If the sides of C are equal and sufficiently small relatively to $a\,b$

$$M = 2\,a\,n\,l\,\frac{a+h}{h}$$

a being the side of the frame, h the distance of the frame from $a\,b$, and n the number of coils in C.

On the other hand, L and L′ may be calculated by the formulæ (1) and (2).

The method furnishes, then, a means of verification of these formulæ.

It is to be observed that the telephone is necessary to observe the variations of the E.M.F. e. If one left the differential galvanometer in communication with the auxiliary wires, the needle on account of its inertia would have obeyed the mean currents traversing the coils. Now, since the integral of the induced currents produced in the successive variable periods is nul, it follows that the mean current would have remained the same in the two branches of the galvanometer. This method has been used for iron, soft steel, copper, phosphorus, bronze, and brass wires. The conductor, for comparison, was a tube of mercury. The results of the experiments on the above non-magnetic metals satisfy sensibly the equation (1). For iron and soft steel the results are in accordance with equation (2), in which k varies from 25 to 30.

We carried the verification further, and took the case of long copper wires, substituting for the inductor C, and for

Digitized by Google

the conductor M N two coils of variable induction. The results again verified the calculation.

We have as yet only studied conductors with circular section (and these are most used in practice).

Hughes has shown that conductors, with rectangular section, have a more feeble coefficient of self-induction than round conductors.

Unhappily conducting bands are little applicable to aerial lines; wind and snow would soon make havoc among such conductors.

Metallic bands have been employed for a long time for the rods of lightning conductors, in consequence of experiments made by Guillemin. This physicist explained the greater conductivity of bands for electric discharges by supposing that the fluid passed off by the surfaces of the conductors. It is seen that the phenomena of self induction give a better account of the observed differences.

Conductors formed by metallic cords act differently according as the metal is magnetic or non-magnetic.

In the first case, the induction is much less than in a conductor of the same circular section. In fact, the circular magnetisation is constrained by the division of the section in the same manner as Foucault's currents are hindered in machines by the employment of bundles of wire. Besides the mean dispersion of the elementary currents is increased. In cords of non-magnetic bodies the differences observed are much less, and they depend solely on the greater dispersion of the elementary currents.

The considerations which we have just presented are of the greatest importance from a practical standpoint. They explain facts which formerly appeared obscure or ill-defined, and they lead to new rules on the establishment of electric lines.

It has been remarked in the United States that the compound wire formed of steel coated with copper is preferable to iron wire of the same conductivity. In such a wire a part of the current passes in the steel core and the other in the copper envelope. These two parallel currents tend to magnetise inversely the exterior layers af the steel core. This differential action diminishes considerably the coefficient of induction of the conductor.

For the construction of lightning conductors, circular iron rods are inferior to cords of the same metal, or to bands of copper.

Conductors of copper or bronze are specially preferable for the transmission of variable currents. The currents on both telephonic and nearly all telegraphic lines are variable, because, thanks to M. Van Rysselburghe's process, telegraphic lines serve also for telephonic communication. Soft copper cannot be employed on aerial lines on account of its feeble mechanical resistance; but it may be replaced by compounds known under the name of bronze.

It will be seen that practice has got the start of theory in the choice of telephonic conductors, and the promoters of the telephone in Belgium ought to be praised for having adopted from the first conductors with a copper base.

A SECONDARY BATTERY OF TWENTY-FIVE YEARS AGO.

During the discussion of Mr. Bauer's paper, read before the American Institute of Electrical Engineers, on "Secondary Batteries for Lighting and Power," reference was made to the work of an early inventor, to whom also Mr. C. J. Kintner referred in his lecture before the Franklin Institute.

Inquiry having been made on the subject, we may say that this inventor, Charles Kirchhof, in a patent granted to him February 26th, 1861, describes a form of storage battery to which many inventors of the present day are referred by the examiners in the Patent Office, and it may therefore prove of interest to our readers to learn of the work of a man who was so far in advance of his time and who came so near the solution of the problem of the practical application of the storage battery.

The patent referred to shows that Kirchhof possessed an intimate knowledge of the previous work in this field, and proves also that he himself must have studied the subject very deeply. After referring to Ritter's charging pile, Grove's gas battery, Poggendorff's polarisation apparatus, to Faraday, Mendler, and others, he enters into the theory of the storage battery, and then shows the new form of battery devised by himself. We quote from his description :—

"A small and powerful regenerator is the following :—A glass (see Fig. 1), A, is closed by a cover of lead, B, to which electrodes of platina-foil, C C, are soldered, diverging from each other as they descend. Said electrodes are perforated, and I roughen them by hammering them between emery paper. They need not be platinised. A glass tube, E, inserted through a hole in the cover B, isolates the positive electrode D of platina, which is suspended in it, and nearly extends to the bottom of the glass, where it spreads and branches around, without touching, however, the other platina-foil. The glass is filled up with a solution consisting of about six parts (by weight) of nitrate of lead, two or three parts of acetate of lead, and one part of nitrate of potash, dissolved in from eight to twelve times the quantity of water. The solution is now filtered and the following added: four parts of

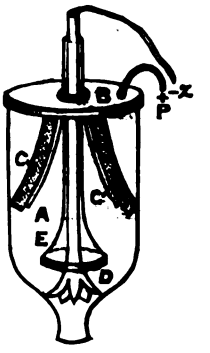

Fig. 1.—Kirchhof's Storage Battery.

acetic acid (liquid commercial at 21 per cent.), one part of nitric acid, and scarcely one-sixteenth part of nitrate or acetate of iron (or nitrate or acetate of zinc). When too much of the iron is taken, the turning of the light colour of the solution into a yellowish one will indicate it. On connecting the cover B with the positive pole P, and the isolated electrode D with the negative end Z of any generator, the foil will turn black peroxide of lead, and the positive electrode will be surrounded by crystallised lead. This is a very positive element, and the former (peroxide) the most negative known to exist, and also a good conductor.

"By changing the proportions of the substances of the solution, more or less peroxide or metal will be deposited, and the conducting power, &c., may be increased or decreased in the same ratio. If pure ingredients are employed in the preparation of the solution, it will last for a long time.

"Metals of a more negative character than the above-named lead (except quicksilver) covering the positive electrodes are often very injurious. This is not the case, however, with the more positive elements. The combination of several cups or glasses is the same as in galvanic batteries.

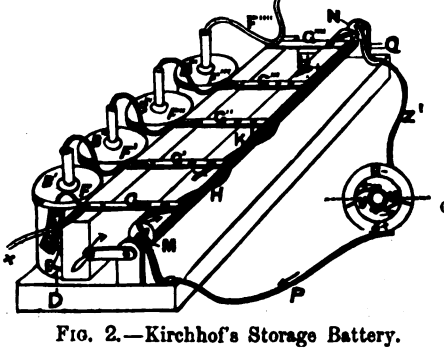

Fig. 3. Commutator.

Fig. 2.—Kirchhof's Storage Battery.

"Platina may be saved by substituting a positive electrode of lead (amalgamated with quicksilver) instead of platina.

"A more perfect apparatus is the double regenerator. Each glass of the same is provided with two pairs of electrodes, each pair acting independently of the other. One pair discharges while the other gets charged. In this manner the quantity of the elements of the solution remains the same. In some cases one positive electrode may answer at the same time for the two negative ones. All regenerators may be used for discharging quantitative currents while being charged"

The patent also describes a "translator" (Fig. 2), the object of which is to charge each battery in succession, while the others of the same circuit are discharging, Fig. 3 representing the commutator of a magneto-electric machine. The points given above are those regarding which curiosity has been aroused, and which constitute the main elements of the patent.—*Electrical World.*

THE CABLE FIGHT CONTINUED.

The battle of rates on the Atlantic cables, begun six weeks ago, is still being carried on with such vigour and obstinacy that, judging by outward appearances, it may last another six weeks—some people say six months—longer. If the several companies concerned in this most deplorable dispute are enjoying the strife, and hoping to reap a permanent advantage by maintaining it till one or other of the combatants is exhausted, nobody has any right to interfere with them. For our part we have already expressed a strong opinion adverse to the COMMERCIAL Company, and favourable to the established Atlantic companies, whose rights it has wantonly invaded. We in no way depart from that opinion now. But there are other interests to be considered besides those of the cable companies, namely, those of the public; and it is on behalf of the public chiefly that we now again return to the subject. Not that the public feels itself in any way aggrieved by what is going on; quite the contrary. Customers of the Atlantic cable wires are having a good time of it, so they think, and probably would thank nobody for putting an end to a state of things in which they seem to be the chief gainers. But they cannot be gainers in the long run, and it is this fact which we would endeavour to impress on the public if we might hope that anything we say will reach its ears and influence its judgment.

When commenting on the conduct of the MACKAY-BENNETT Company just before the commencement of hostilities, we described the circular asking their patrons to rally round them and pay one shilling for what could be got elsewhere for sixpence as a downright absurdity. Our contemporaries endorsed this description, and the circular was met with a general volley of ridicule on our side the water. But we seem to have over-estimated the shrewdness of our American cousins, or perhaps under-estimated the astuteness of the framers of that singular document. It has been openly asserted that the COMMERCIAL Company had not played the game of competition fairly; that by offering rebates to its best customers it had been in reality accepting messages at lower than the nominal rates, and thus taking an unfair advantage of its competitors. This, it is alleged, was one of the grounds on which they decided to compel the offending company either to join them in a common pool or to face the consequences of a ruinous reduction of rates. Rejecting the friendly overtures, it was open to Messrs. MACKAY and BENNETT to have either persisted in maintaining their favourite rate of 40c. per word or gallantly reducing it to 6d., like their opponents. They did neither; they reduced it to 1s., and appealed to the philanthropy of their customers. At least, this is what they seemed to do. But our latest information points to the conclusion that in reality 1s. is only their nominal rate, half of which is to be refunded if the company succeed in wearing out the attacks of its adversaries, and re-establishing the 40c. scale. Under this pledge a fairly good business is said to be doing; at all events among its American friends, who are thus made partners in a game which it is their interest, and theirs alone, to win.

Such is, no doubt, the customer's view of the matter. He wants to prevent a return to the old rates which prevailed before the MACKAY-BENNETT cables were laid, and the only way to insure this is to keep them solvent by patronising them freely, which he can do with a good business conscience, seeing that for every shilling he spends on them he is to get sixpence back again. It is true there is an "if" in the bargain; but so there is in most speculations; and this, on the whole, does not seem a bad spec to the Yankee mind, perhaps chiefly because the cables and their owners are Yankee likewise. But meanwhile these owners are not only taking charge of the "if" above referred to, but getting possession of the shillings. The chances of the sixpences ever going back to the customers' pockets seem to us exceedingly remote. Truly it is the interest of the customers to win this battle of the rates; but the longer it lasts the more will it be to Messrs. MACKAY-BENNETT'S interest to lose. In the first place, they will have to refund nothing if—much to their regret, of course—they are obliged to cave in. And, secondly, they have nothing to lose by yielding to the pressure of their powerful rivals; at least, nothing compared with what they will lose if the contest be prolonged, and if at the end of it they may only return to a rate which, however they like it on sentimental grounds, is proved to be an unremunerative basis for practical cable business. We do not say that the COMMERCIAL people are riding for a fall; but if they are, they have prepared a nice soft place to fall upon.

The mistake the Americans have made all along is in supposing that any set of business men, whether many or few, will invest large sums of money merely for the purpose of doing the public a good turn. Even if there are such persons to be found, the public have no right to their self-sacrificing services; for the community has as little claim to be served telegraphically for nothing, or next to nothing, as it has to get its cock-tail or its bread and butter for nothing. The proprietors of the COMMERCIAL cables are very worthy people no doubt, and they wished to break up what they con-

Digitized by Google

ceived to be an injurious monopoly. But they did not wish it to the tune of a million and a half of their own money without some expectation of being rewarded for their good intentions; for if they did they might have convinced us already by making us a present of their cables, which they do not seem at all inclined to do. When, therefore, they appeal to us for support, on the ground that they are sincerely desirous of establishing a particular cable rate merely because it is lower than the competing cable companies can afford to adopt, we suspect that we are being treated either as knaves or fools. Even if we admit, which we are unable to do, that the COMMERCIAL cables can be worked at less expense than the rest, it is obvious that two cables cannot do all the work; and it is simply monstrous to expect that the pioneer cables shall be worked at a loss because some later cables have been laid at a less cost. The only fair rate of working is that which will yield a fair profit to all alike concerned. That the COMMERCIAL people are not willing to do business on this understanding is evident from their refusal to come to a joint purse arrangement with the older companies.

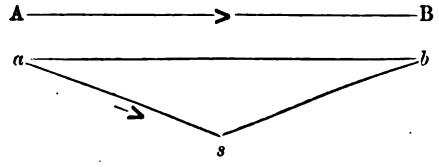
The new company ought to know its own business best, and as a mere matter of business we must let it fight its own battle; but when it comes to the public as a benefactor we take leave to dispute its pretensions. Nobody can honestly believe that it will make great sacrifices—present and contingent—for the benefit of the telegraphing public, much less that it is going to ruin itself rather than charge the public a rate which alone can pay interest on its outlay. The COMMERCIAL Company can no more be credited with disinterested motives than the enterprising storekeeper whose anxiety to give away cool drinks to senders of telegrams we report in another column. Certain members of the public may profit by it in the matter of cool drinks while the summer lasts; but, as regards the cabling public, we would remind them that they will have to pay for this battle of rates, whoever wins or loses. Rates are likely to be higher—not lower—for the temporary squabble which has reduced them to an impossible figure. Cool drinks in the shape of prospective premiums on every telegram sent at a high figure mean either deliberate fraud or reckless delusion. And a similar remark applies to those who enjoy the present advantage of low rates without any meretricious inducements thrown in. They will have to pay the piper by and bye. Meantime the companies whose rates are lowest are enlarging their business and widening their circle of customers. And although the increased traffic probably does not yield a profit at present rates, it creates a basis for improved prospects whenever a rational tariff may be again restored. In the true interests of the public we hope that this consummation may not be long delayed.

CORRESPONDENCE.

CURRENT INDUCTION AND LENZ'S LAW.

TO THE EDITOR OF THE ELECTRICIAN.

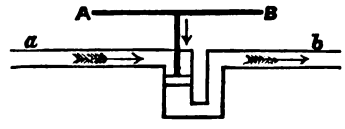
SIR: At an early stage of my heretical views about the process of induction, it was pointed out to me by a friend that my tenets were in direct opposition to Lenz's law. The antagonism which here exists will be made more clear if I deal with one particular case. When A B, part of a current-bearing circuit, is moved down upon *a b*, part of a passive circuit *a b s*, a current is found to flow through *s* during the operation, in the direction shown, and at the same time we experience a resistance to the movement of approach. These are the facts with which Lenz's law deals. With facts, however, I am not at variance; my quarrel is with the *rationale* of Lenz's law, which traces a certain connection between the resistance to the movement and the direction of the current induced in *a b*. According to the usual view of induction, it is *inferred* that the current through *s* passes all round the circuit, and therefore from *b* to *a*—viz., inversely to the direction of the current in A B. And thus the opposition to the movement of approach is attributed to a repulsion between the two wires, it being known that "inverse currents repel each other." Meanwhile, from my own point of view the current between *b* and *a* goes the other way, and is not inverse but direct in respect of



the primary current A B; so that Lenz's reason no longer applies. I thus impose on myself a twofold task. First, I must account for the mechanical resistance experienced without reference to any inverse, repellant currents, whose existence I disbelieve in; and, secondly, I must explain why the currents, if flowing, as I represent, both in the same direction, do not positively *aid* the movement of approach by their mutual attraction.

I. As regards the resistance experienced, there is no need to go in search of repellant currents to explain its existence; it is an *a priori* necessity, depending upon fundamental principles about action, work, &c. If the work of driving the induced current is done *ipso facto* by moving A B closer to *a b*, we are sure to experience an equal and contrary reaction according to the resistance overcome in executing this action. Briefly, if moving A B drives the induced current, the movement is sure to engender resistance to itself. I might make a similar remark about the reaction upon the primary current, known as the counter E.M.F.; for the primary current with its magnetic faculties is a co-factor in driving the induced current.

II. Next I have to answer the objection—Since parallel currents in the same direction attract one another, does not the heterodox theory require that the induced current should *attract* A B and encourage its approach? I reply that it makes all the difference whether the current in *a b* is due to some independent cause, or is produced by the approach of A B. In the latter case there is no reason why attraction should occur. A hydraulic illustration will best explain the matter. A current of water in the direction of the arrows, proceeding from



some independent cause, would doubtless draw down the piston and its cross-bar A B (which represents the attraction of parallel currents of similar direction); but if the current in the pipe is simply the result of pushing down A B (which represents inducing an electric current by the approach of the primary wire), no man in his senses will imagine that such a current will lend any active assistance in the pumping. In the same way the induced current caused by the approach of the primary wire is merely the process of yielding by which the movement is permitted. Undoubtedly this induced current does, in a *permissive* sense, favour the movement of approach; but it does not actively *assist* that movement. Otherwise we should have to throw away that good old maxim, *ex nihilo nihil fit*.

I cannot conclude without making one reflection upon the above hydraulic illustration. It seems to me to point out, in virtue of a general principle, that whatever may be the nature of that invisible molecular mechanism which connects the primary and secondary circuits, the current induced by a movement of approach can only be of such a kind as would cause attraction if independently produced, and that consequently the commonly accepted idea of a repellent current induced by approach is a physical impossibility.—Yours, &c.,

37, Burlington-road, W. E. ALDRED WILLIAMS.

MILITARY TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your interesting leader in last week's issue was particularly welcome to me, as it contained an expression of opinion on a subject which I was anxious to see brought forward at the discussion on Capt. Cardew's important paper. I was pleased to see that your article shows a decided preference for the Sounder as a military telegraph instrument. I expressed this opinion myself at the discussion on Capt. Cardew's paper, but should have naturally preferred for that opinion to have emanated from any of the officers experienced in military telegraphy.

The expression of one or a dozen opinions in favour of the efficient working of non-recording military telegraph instruments does not settle the question of their admissibility in a well organised army; nor does Mr. Donovan's reply to my question, as given at the discussion, in which he mentioned the well-known fact, so minutely described in Mr. Plum's lengthy work*, that "throughout the American Civil War non-recording sounder instruments were employed," as it is not proved in any way that American army organisations would be the proper organisation for European warfare.

I should like to say a few words on this subject; but before doing so wish to remove a slight error made by Captain Cardew, and by which the writer of your leader seems to have been influenced, which error is shown in the following words of the lecturer, viz.:—"The system, which was invented by me five years ago, has been kept secret by us hitherto." This is not quite correct, as Captain Cardew's apparatus was brought forward and explained to the public over two years ago.

Not going into the question of the supposed liberality with which you credit the War Department in letting everybody into its secrets, I may state that Captain Cardew's Vibrating Sounder has been mentioned, described, exhibited, or publicly explained on the following occasions:—"Telegraphing across the Solent without a Cable," published in the *Military Telegraph Bulletin*, March 15th, 1884, London, edited by Major C. Beresford, R.E. (Trübner and Co.). "Notes on Military Telegraph Instruments," by Major N. F. Turner, R.E., revised edition, London 1884. A copy of this very perfect book of information was presented by its author to the library of the Society of Telegraph-Engineers, and has been at the disposal of anyone interested.—"Review of Major Turner's above-mentioned Book," published in the *Military Telegraph Bulletin*, 15th September, 1884.—"Our Field-Telegraphs: its Work in Recent Campaigns, and its Present Organisations." Paper read by Lieut.-Colonel A. C. Hamilton, R.E., before the Royal United Service Institution, on February 15th, 1884, Major-General Sir Andrew Clarke, K.C.M.G, C.B, C.T.E., R.E, in the chair. On this occasion the vibrating-sounder was not only spoken of by the lecturer, by Lieut.-Colonel R. N. Jelf, R.E., and by Major Armstrong, R.E., but it was also exhibited and worked by non-commissioned officers of the Telegraph Battalion, and after the lecture it was minutely explained to everybody interested.—"The Inventions Exhibition at South Kensington," during the summer, 1885. A Cardew vibrating sounder was exhibited during six months, and inspected by thousands of people.—"The Field Telegraph: its Use in War, and its Employment in the late Expeditions in the Soudan and South Africa." Paper read in April, 1886, by Major C. Beresford, R.E., before the Royal United Service Institution. On this occasion Captain Cardew exhibited and fully explained his own apparatus.

Even a telegraph clerk of the Royal Engineers possessing a poetic nature, dismounting from the telegraph station waggon and rising upon his own Pegasus, dedicated an elegy to the musical "buzzer," animadverting, long before Major Beresford, on the buzzing sounds so trying to the ear. This piece of poetry appeared in the *Military Telegraph Bulletin* of April 15th, 1885.

With these remarks, which could be easily increased *ad infinitum*, there is not a shadow of doubt left that the paper read at the last meeting of the Society of Telegraph-Engineers revealed nothing particularly new, nor gave publicity to anything hitherto kept secret. Fortunately there is no secrecy in the organisation, formation, and material of any military telegraph, and as regards the "material" there could hardly be any. The very nature of the telegraph lines, stretched over immense distances, distributed over numerous stations, exposed to the eyes of thousands of people, often left behind in warfare, &c., all forbid secrecy. Thus, Major Beresford's pithy remark, that "the army which has the most efficient system of electric signalling will hold a trump card which may exert a decisive influence on the game in any future European war" is perfectly correct, but does not refer so much to the "material" as to the "*personnel*." In this latter centres the efficacy of a field telegraph service.

With your kind permission, Sir, I will now make a few remarks with regard to two points—viz, the efficiency of Captain Cardew's "Vibrating Sounder," and the question of admissibility of non-recording instruments in active service.

With regard to the efficiency of the apparatus, I believe that Captain Cardew did not bring forward at the Society's meeting all the arguments that might be used in favour of his own apparatus. Thus, for instance, Colonel (then Major) Turner, R.E., reported in his "Notes on Military Telegraph Instruments, with Diagrams of Connections," a book made public in 1884, as already mentioned, that "this system has been successfully worked through 15 miles of bare wire lying on the ground, and even when a part of the line was thrown into a canal the signals were perfectly readable."

Then Colonel Hamilton, R E, on the 15th February, 1884, lectured at the United Service Institution and said: The "vibrating transmitter has been introduced into our field telegraphs on account of the marvellous power which this arrangement has for being used on a defective line, so that in such a case as a bare wire lying on the ground from the poles being knocked down, or (as was sometimes the case in South Africa) the insulation being burnt off the cable by grass-fires, the transmitter would convey messages with great distinctness, whereas there would be an insufficient current received to work a recorder or a sounder. But the instrument has some defects, owing to its great sensitiveness, which rendered it, however useful on special occasions, unsuitable to the ordinary traffic of the service."

This was corroborated by No. 7, of the *Military Telegraph Bulletin* of the 15th of September, 1884, in the following words:—"Means have also been provided by Capt. Cardew's vibrating sounder, in combination with telephone receivers, to transmit messages for many miles through a wire lying uninsulated along the bare ground, and thus communication can now be effectively maintained under conditions which, a few years ago, would have rendered it impossible."

This information induced me more than a year ago to experiment with a vibrating sounder, and the following results of three experiments will give further evidence of the high efficiency and valuable qualities of the apparatus, especially when it becomes a question of working a badly insulated line.

1st Experiment.—A double wire circuit, having an artificial resistance of 100,000 ohms, with a vibrating sounder at one end and a telephone at the other; the line circuit being short-circuited half way by only 2 ohms resistance. With this arrangement the telephone received the vibrating Morse signals perfectly, with a battery power of only two Leclanché cells.

2nd Experiment.—Same arrangement as above; but instead of short-circuiting the line wire, the poles of the battery were short-circuited with a resistance of 2 ohms; the result obtained being as favourable as before.

3rd Experiment.—Line consisting of a single naked copper wire of 2 mm. diameter, 130 yards long, having an earthplate at each end. Ninety yards of this wire were thrown into the River Thames, and to the remaining 40 yards on shore, which were suspended on poles, an artificial resistance of 40 ohms was added. With this arrangement the distant telephone received the vibrating Morse signals with a battery power of six Leclanché elements; resistance of vibrating sounder eight ohms, and of telephone four ohms.

Capt. Cardew's experiments, as well as those just mentioned, demonstrate the valuable qualities which this apparatus possesses, the chief of which may be summed up as follows :—

1. Possibility of telegraphing on badly insulated lines.

2. Employment of fewer cells, thus reducing weight for transport.

3. Light weight of apparatus, also facilitating transport; simplicity of construction, requiring little adjustment for altered condition of currents.

4. Note signals are more easily read than interval signals.

The utility of the Cardew vibrating sounder is thus established beyond doubt, and as its good qualities are exactly those required in field telegraphy, it is but natural that this apparatus should be hailed with satisfaction by everyone interested in this branch of the telegraphic profession. The possibility of working with very light wires of considerable strength, but badly insulated, is identical with the possibility of advancing telegraphic communication more towards the front, and thus increasing the hitherto limited sphere of field telegraphy. In this consists the prime value of the vibrating sounder.

But, alas! there is no rose without thorns. The vibrating sounder is a non-registering instrument, and can such be safely adopted by a well-organised service for military reports? This leads me to my second point.

I fully agree with your leading article that before we venture to discuss such a question it is necessary to define what we mean by military telegraphy. The object of such a service is to facilitate and hasten communication between more or less detached bodies of troops during military operations. Such operations, however, being of very distinct nature and variety, it follows that the telegraph service in the field must before all be adapted to the nature of the warfare on the spot. In this respect there are two main distinctions, viz., "advancing warfare" and "warfare in position." The two things are not identical, and the conditions to which the military telegraph service are subjected in the one case may be totally different in the other.

You mention in your article a "military telegraph which is always in front of the army." Is this not a theoretical aim only, and not a practical reality based on the history of the service? I accept the description with regard to warfare of position; but since electricity has been discovered the cases of a telegraph being in front of an army on a European theatre of war and in combination with the more important part of modern warfare—that of rapid advances—could certainly be counted on the fingers of one hand, and I even doubt if so many cases as that could be found. With the exception of the brilliant and unique telegraphic action of Colonel Sir Arthur Mackworth, C.B., R.E., during the short but glorious 1882 Egyptian campaign,* where the field telegraph acted on the battlefield at Tel-el-Kebir and also at reconnoitering expeditions, there is no case on record of an English field telegraph section having been at the front of the army during times of advancing warfare, and Sir Arthur's action took place during a campaign out of Europe, one of short duration and of limited extension. The telegraph operations during the Abyssinian, Ashantee, Zulu, Bechuana, Transvaal, Afghanistan, and Soudan campaigns had all the character of Etappe lines. The likewise brilliant telegraphic operations of Colonel Turner and Major Beresford at the front during the Eastern Soudan campaign could hardly be classed with "advancing warfare," as Major Beresford himself stated† that "the expedition which started from Souakim with Berber as its object did, in fact, not go more than twenty miles up country."

With regard to warfare in position every military authority agrees that troops operating under such conditions ought to be provided with every possible means of telegraphic communication, electrical as well as optical, and that these communications ought to extend over the entire field of operations, with ramifications beyond the head-quarters of army corps to the very outposts of the lines.

So far we meet with no difference of opinion; but when approaching the subject of telegraphic operations during "advancing warfare" we suddenly find ourselves upon a field of most diverging opinions. Major Beresford said, and many officers of various armies have long ago made similar remarks, "that in any future European war the army whose vedette and outpost service was equipped with efficient telegraphic appliances would possess a trump card of enormous value;" whilst other officers, also experienced and seasoned in telegraphic warfare, say just the reverse. Thus, for instance, Captain Baron von Massenbach in his article,* speaking of the German military telegraph organisation, says (pp. 138 and 140):—"Before all, we must point out that, as far as we know, an acknowledged necessity for an outpost telegraph service—that is to say, any mechanical means of communication forming an integral part of an army, does not even exist. Although we do not doubt that such a communication might occasionally be of convenience—in some situations even of advantage—to the strength of the army, we doubt very much whether the advantage gained in this respect is not lost many times over in other ways by adopting such a system. We flatly deny that, with the exception of a siege, an outpost telegraph could contribute a perceptible increase to the fighting capacity of the troops." Further on Captain von Massenbach says: "Let such outpost performances be transferred to our battlefields, and we will see where the telegraphists remain, where a judicious application of electricity ceases, and where child's-play begins," &c.

That these principles are followed in the German army is shown by the fact that the Field Telegraph Reglement only prescribes the daily connection between the base of operations with the great head-quarters and with the head-quarters of the armies. Telegraphic connection between these latter and the head-quarters of their army corps does not belong to the regular programme of German field telegraphy, and is only aimed at on special and favourable occasions, whilst still further advanced telegraph lines, for the purpose of connecting divisions or outposts, are not only excluded but are considered inadmissible during "advancing warfare."

I cannot help regretting that your leading article of the 4th inst. bases its criticism of German army telegraphs on pictures of illustrated periodicals. This detracts from the value of arguments, and leads to misapprehension. Besides, it remains an open question whether "pedantism" in military matters is a virtue or a vice. Anyhow, German telegraphists have not been so "comfortably seated at fitted tables" during the Franco-German war as those illustrated periodicals would make people believe. Evidence of this is given in the following figures:—During the time from the 16th of July, 1870, till May, 1871, the German Military Telegraph Department erected 27,841½ kilometres (17,293 English miles) of telegraph lines and 569 telegraph stations† for purely military purposes. If we compare this working efficiency with that of the military telegraphs during the civil war in North America, and with that during the last Soudan campaign, we have the following official figures :—

The total number of miles of U. S. military telegraph lines constructed,‡ including field, land, and submarines lines, amounted to 15,389 miles, occupying in time from the 12th of April, 1861, till the 1st December, 1865.

According to Major-General Webber, C.B., R.E., there was erected during the late Soudan campaign a grand total of 1,536 miles of line,§ ending at Hamdab, a couple of hundred

miles at the rear of the operating front of the English expedition, and occupying in time for its establishment from the 18th of September, 1884, till the 1st of May, 1885.

If we bring these figures to an equal standard of time, we find that the actual working capacities of military telegraphs during the Soudan, the United States, and the Franco-German campaigns, stand in approximate proportion as 1 : 1¼ : 8½ respectively.

The conception of the "comfortably-seated German field telegraphist" most likely arose from the fact that the German Etappe lines even employed the Hughes printing apparatus, and this with very great success. Within a few months more than one million telegrams were handed over to the Versailles military telegraph station and promptly forwarded to Berlin, principally by the Hughes printer, hence "printed tape was sometimes delivered to commanding officers." The Hughes, as a military apparatus for Etappe trunk lines, possesses many advantages, amongst others that kidnapping of messages along the line is impossible. Such performances during the American war frequently happened at the front, but in a European theatre of war this could only happen at the rear. Therefore, under stable circumstances, during warfare of position, on main Etappe lines, the Hughes printer is an efficient military telegraph apparatus.

Now, whatever the drawbacks of the German military telegraph organisation may be—and there are some very serious ones—her so-called "pedantic" proclivities have, as proved by above figures, not interfered with her working capacity, which reduces that of the United States telegraphs to quite a secondary achievement, and meets no competition in the annals of the use of telegraphy in war.

After these facts I can now easily bring forward my last point. As already stated, the German army does not recognise the necessity and admissibility of an outpost telegraph service in "advancing warfare," hence she objects to any apparatus for such purpose, be it a vibrating-sounder or a telephone. The apparatus for outpost service during "warfare in position" are always recording instruments, and this kind of station apparatus is under all circumstances preferred to any audible apparatus. I mentioned this at the discussion on Captain Cardew's paper, and I now give as follows a few remarks of modern writers confirming this proposition, based upon German war telegraph experience:—

Major-General von Chauvin, whose distinguished fortune it was to command the military telegraph during the Danish, Austrian, and French campaigns, says on page 17 of his book: "Field telegraph apparatus must be simple and strong, easily manipulated and transported, and as little as possible influenced by changes of temperature, climate, or electrical changes of currents; and, above all, they must produce a record of the telegrams." And on page 87: "The use of the telephone, although a non-registering apparatus, could be exceptionally admitted on telegraph lines in fortified places, in order to connect detached forts with the commandant's headquarters."

Then again, Captain von Massenbach writes in 1885 (page 147) as follows:—"We consider both apparatus, the sounder and the telephone, as inadmissible on principle. We consider the loss of every control of the telegraph service, the abandonment of documentary confirmation of correspondence, and the want of responsibility of the corresponding parties, as entirely incompatible with the principles governing our army service and that of military reports and orders in the field. To introduce into our highly disciplined army, where the sense of duty and responsibility is diffused into the lowest branches of the service, an element so unsolid and uncontrollable would, indeed, not be a luxury, but an evil." "Who would in warfare sanction the possibility, nay, the likelihood, of numerous uncontrollable errors and mistakes caused by such an outpost telegraph—all such errors beyond control, and chiefly committed by subordinates, but sometimes incalculable in their consequences? Then, besides, in a foreign country, with foreign names to telegraph! Our conclusion is simple. Should an outpost telegraph be insisted upon, then let it have recording apparatus; but even this would be difficult to combine with our army organisation. Its technical prospects would be doubtful, its tactical prospects insignificant, the army does not ask for it and will never require it, hence—away with it!"

At page 262 the same writer says:—"The severe and scanty form of military intercourse, the never-ceasing and strict control of the service, are points which give the recorder a decided advantage over any non-recording instrument."

Then again: "The best constructed apparatus, the clearest and most correct notions of its application for war purposes have not yet produced successful results, and will not as long as the motive force bears the character of unreliability. If telegraphy is to become a factor of strategical calculation, then its failure must be quite an exception and not a probability."

Much more evidence against the use of outpost telegraphy in advancing warfare, and against non-recording military apparatus in general could easily be produced, but I must apologise for having already so far trespassed on your space. I have not expressed here my own opinion on the question, but this I have published repeatedly in several treatises on military telegraphy.* I, however, repeat here what I said at the discussion on Captain Cardew's paper, that under certain circumstances I am in favour of outpost telegraphy and of non-recording instruments, and there is no doubt that the vibrating sounder is the most suitable of all. In raising the question of admissibility of non-recording instruments for military telegraphs, my sole object was and is to invite officers of experience to exchange their opinions, and thus to contribute to the settlement of differences of opinion which certainly exist, and which so vitally influence the adoption of non-recording instruments in general. I am thankful to Major Beresford, Mr. Donovan, Captain Cardew, and, above all, to *The Electrician's* leading article, for having already expressed their opinion; but as none of these are given with the completeness which the importance of the subject merits, I hope that fuller accounts, expressed in a "service-like" manner, will come forward.—Yours, &c.,

R. VON FISCHER-TREUENFELD,
late Commanding Officer of Army Telegraphs.

The Glen, Balham, London, S.W., June 8, 1886.

ELECTROLYTIC TREATMENT OF ARGENTIFEROUS ZINC.

At Friedrichshütte, in Silesia, the following modification of the treatment of the zinc, lead, and silver alloy obtained in desilverising lead by Parkes's process has been introduced. The zinc-skimmings, averaging lead 90, zinc 8-10, and silver 0·5-2·0 per cent., are granulated and placed in a layer at the bottom of a lead-lined tub filled with a solution of sulphate of zinc, forming the electrolyte. The positive electrode is formed by the lead plate at the bottom, while the cathode is a zinc plate suspended vertically in the liquid. When a current of sufficient strength is passed through the apparatus zinc is deposited on the cathode, a corresponding quantity of the metal being dissolved from the granulated alloy, so that the strength of the solution is kept approximately constant. The decomposition goes on until the residual alloy, which may be about one-half of the regular quantity, is protected by the excess of lead from further action, when it is washed, dried, and subjected to liquation. By the latter operation lead is separated of sufficient purity to be passed at once to the refinery, while the residue contains zinc and lead in about the same proportion as the original zinc-skimmings, and is of the same fine-grained character. This is subjected to the electrolytic process a second time, followed by subsequent liquation. By these alternate operations, zinc, lead, and silver are obtained

in the metallic state, instead of the mixed oxides of lead and zinc formerly produced in considerable quantity, which could only be made marketable with difficulty.—*Proc.* Inst. Civil Engineers.

EXPERIMENTS ON INDUCTION CAUSED BY MOTION.*

When a conductor is moved in a magnetic field currents are generated in it. Again, when a conductor traversed by a current is placed in a magnetic field it tends to be displaced in accordance with the rule of Ampère. These two phenomena are generally verified by employing solid conductors to place in the magnetic field; but there is evidently no reason why we should not employ liquid ones.

It is exactly on this employment that the mercury galvanometer of M. Lippmann is based, which gives a displacement of the mercury in the magnetic field when this liquid is traversed by a current. But it is known that M. Lippmann has also shown that this instrument is reversible, and that if we put the mercury in motion mechanically there is a development of electricity.

The currents which result from this induction in the mercury ought to be regulated by the law of Lenz—that is to say, they ought to be so distributed that by their electro-magnetic action they oppose the motion which gives them birth, producing the same resultant effect as a sort of friction in the magnetic field.

It may be proposed to arrange the experiment specially with the aim of showing this particular effect. For this purpose the iron core of a horse-shoe electro-magnet is terminated in two rectangular pieces of iron, which almost meet, but are just separated by a thin piece of cardboard, which is pressed tight between them. This cardboard is cut away in the centre, so as to make a channel between the rectangular pieces of iron which form the poles. This channel is very narrow in the direction parallel to the lines of force (the width being only the thickness of the cardboard). Perpendicular to the lines of force, however, it is much wider, and it widens out particularly at the centre, where the cardboard is most cut away. The two rectangular pieces of iron are encased in two sheets of wood or ebonite, and in these two glass tubes are fastened which meet the channel between the poles (formed by removing part of the cardboard). One of these glass tubes is connected with a reservoir of mercury by a caoutchouc tube, and the other ends externally in a fine point. The mercury can thus be made to flow between the poles of the electro-magnet, and, on emerging from the fine point of the glass tube, it forms a parabola as it falls. According to the direction of this pointed glass tube the mercury may have either a horizontal or nearly vertical velocity on emergence, and the form and range of the parabola will depend on the rate and direction of this velocity.

When the jet is well established, if a current is sent into the electro-magnet, the range of the jet immediately diminishes. and this diminution lasts as long as the current. This proves that the creation of the magnetic field in the channel opposes an obstacle to the free flow of the mercury.

This experimental arrangement has the advantage of enabling you to show clearly the strengthening produced in a current traversing a circuit by the extra-current of induction which arises on breaking the circuit. In fact, when the circuit of the electro magnet is opened, the summit of the new parabola, formed when the circuit was made, instead of returning immediately towards its primary position, undergoes first suddenly a slight further lowering, to rise again to its first level immediately afterwards.

It is easy to show the presence of the developed induction currents by introducing into the moving mass of mercury the extremities of two platinum wires. These currents are perpendicular, both to the direction of motion and to the lines of force of the magnetic field where they are developed. Hence these platinum wires should be introduced into the edges of the thin sheet of mercury which flows between the poles where the cardboard was removed. For the strongest effect the lines joining the extremities of the platinum wires should be perpendicular to the line of flow. A galvanometer, which is inserted between these wires, will show a deflection during the flow of the mercury, and this deflection will be reversed, either by reversing the magnetisation, or the direction of flow.

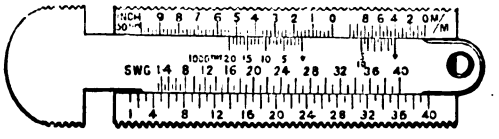
The E.M.F. thus generated will be constant as long as the flow of the mercury is constant, and it will vary with the velocity of the mercury.

The internal resistance and the E.M.F. are here both weak; hence, to show the production of the current readily, a galvanometer of small resistance should be used.

* Abstract of a paper by M. E. Colardeau in the *Journal de Physique.*

AN IMPROVED STANDARD WIRE GAUGE.

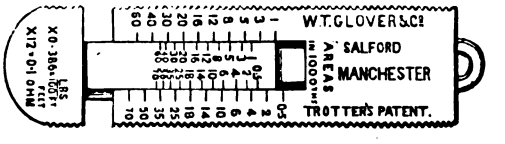
In our issue of 7th February, 1885, we noticed Mr. Trotter's then new wire gauge, and we have pleasure in again referring to it, in order to indicate the latest improvements. In its present form the gauge will register the legal number of any wire between No. 1 (·3in. diameter) or No. 40 (·0048in. diameter). Those who refer to our previous notice will see that it formerly only registered up to No. 6 (·192in. diameter) of the scale styled the S.W.G. (standard wire gauge). To those who are not familiar with the working of this particular scale, we may mention that the readings are obtained by the coincidence of the respective numbers.



Our illustration shows the gauge open, and is assumed to have just measured a wire which should have been No. 8, but which was rather under the size; hence the top figure has not quite reached its fellow on the lower part of the gauge. Had the wire been its proper diameter, it would have pulled the two figures No. 8 directly over each other, and the top and bottom marks would have appeared as one line.

It will also be observed that the inch scale gives the diameter in millimetres and the m/m scale the diameter in millimetres. It is worthy of mention that the inch scale gives a direct reading to a thousandth of an inch, and the m/m scale to a twentieth of a millimetre.

A further improvement, and perhaps the most important, is the extension of the area scale. This scale indicates the area in square inches of the wire that is measured, and works simultaneously with all the others; and therefore when a wire has been measured, its number and diameter ascertained, we need only turn the gauge over and there we shall find the area in *thousands of a square inch.* A reference to our engraving



will show what we mean, as the figures which *coincide* give the reading (like those of the S.W.G.). We should observe that the 20 marks are all but in accord with each other. Had our wire been a No. 8, as it should have been, then the area figures No. 20 would have paired each other correctly. By bearing in mind that only those figures are read which coincide no difficulty will be experienced in using this novel little instrument.

This area scale has other advantages, *e.g.*, if it is decided to run a current on the basis of 1,000 amperes to the square inch, then the readings may be taken as amperes direct, or if 2,000

Digitized by Google

to the square inch, then the area multiplied by 2 gives the current a wire will carry on this basis. If the figures of this scale be taken simply as thousands, and multiplied by 0·4 (more accurately 0·386), we obtain the weight in lbs. per 100ft. of the wire measured; or, if multiplied by 20·35, we get the weight in lbs. per mile; multiplying by 12, we get the length in feet of copper wire, having a resistance of one-tenth of an ohm. 42·8 divided by the area gives the resistance in ohms per mile. Many other uses will, doubtless, suggest themselves to those who may use the gauge; in any case it appears to possess advantages which will readily commend it to electricians, wire users, and wire measurers generally. Now that the American Convention has recommended the use and adoption of our imperial standard for wires, perhaps our American cousins may find in this clever invention a by no means unworthy assistant in the attainment of such a desirable object.

The gauge has been brought out by Messrs. Walter T. Glover and Co., Salford, Manchester.

RESEARCHES UPON THE SELF-INDUCTION OF AN ELECTRIC CURRENT.*

BY PROF. D. E. HUGHES, F.R.S.

(Concluded from page 96.)

Influence of a Magnetic Sheath.

The remarkable phenomenon wherein a non-magnetic metal such as copper shows a higher "variable" resistance when under the influence of an external coating of iron than a wire of solid iron (and this notwithstanding that the resistance of the side of the bridge is kept a constant or by balancing its resistance on the opposite side G D as mentioned) seemed worthy of experimental research.

Experiments were made in order to find what form of conductor would give the maximum increased resistance in the variable period, and I found that an external tube of iron insulated from its central core produced this effect, for if the tube was not insulated but joined in electrical contact the results were reduced, due, I believe, to a transversal neutralisation taking place in its own portion of the wire, as I have mentioned in my reply to the discussion on my first paper.

TABLE III.—Influence of an Iron Tube upon an Interior Insulated Wire.

Iron gas tube, 90 cm. in length, 10 cm. diameter, 2 mm. thick. Wires 1 metre in length, 3 mm. diameter.	Comparative force of the extra currents.	Resistance in ohms, stable period.	Resistance in ohms, variable period.	Percentage of increased resistance in variable period.	Absolute increase of resistance in ohms.
Copper wire alone.	82	0·00460	0·00482	7	0·00022
Copper wire insulated in the interior of the iron gas tube	410	0·00460	0·03220	600	0 02760
Brass wire, ditto..	410	0 01380	0·03974	188	0·02594
Iron wire, ditto...	615	0·02944	0·05888	100	0 02944
Lead wire, ditto..	410	0·05750	0·08682	51	0·02932
German silver wire, ditto	410	0·07636	0·10384	36	0·02748

Table III. shows the effect produced upon an electric conductor by surrounding it with an insulated sheath of iron. It will be seen that the magnetic reaction of the tube upon the primary current passing in the wire produces a marked effect upon the different metals; the force of the extra currents as measured by the induction balance rise in value from 82 to 410, this being a constant for all metals except iron, which alone shows the higher force of 615. The force of the extra currents, however, has no direct relation to the extra resistance shown in the variable period, but the latter must be in direct relation with the duration or length of time required to pass from an infinite to the stable resistance.

The table shows on comparing the resistance of a metal in its stable period with that found in the variable, that copper has the highest percentage of increased resistance, being 600 per cent. increase, or seven times that found for its stable resistance, each metal in the order of their specific resistance having a less percentage of increased resistance until we arrive at the German silver wire, which shows only 36 per cent. against the 600 per cent. of the copper; we have also here the remarkable fact that iron even with a circular section stands simply in its order of specific resistance, showing only one-sixth of the increased resistance experienced by copper; the percentage of increased resistance of a metal when under the influence of an insulated magnetic sheath is directly as its conductivity or inversely as its specific resistance.

If we regard the phenomenon from a different point of view, confining ourselves simply to the additional resistance above that of its specific stable resisiance, all metals whether magnetic or non-magnetic have an almost invariable quantity dependent entirely upon the coefficient of the electro-magnetic action of the iron tube, and independent of the resistance or nature of the wire.

The experiments with an insulated iron sheath may be considered as a forced condition which does not occur or need not be taken into account, but the reaction of the iron tube is evidently electro-magnetic, and as our atmosphere is also magnetic, we may assume that its reaction would be similar, though in a far less degree to that which I have shown.

Submarine Cables.

The influence of a magnetic sheath upon an external insulated wire is one of vast practical importance in relation to our electrical submarine cables, as they are all constructed with an insulated wire surrounded by a spiral sheath of exterior iron wires. In order to study this question I made several cables of short lengths (1 metre) and found (most fortunately for our practical applications) that when the exterior iron sheath is divided as in a cable, or when the sheath consists of several large wires in close contact, that its effects are reduced to a mere fraction of what it would be if the external sheath was a continuous tube; this is entirely due (as I have shown in the case of stranded wires as compared with solid) to the imperfect formation of circular magnetism. I will cite a few examples illustrating this.

A cable was formed of a similar copper wire and insulation to that shown in Table III., the iron tube being replaced by eight iron wires (of 2 mm. diameter each) wound with a slight spiral of five turns per metre, this showed but 100 per cent. increase in the force of the extra currents against 400 per cent. increase when the same wire was in the iron tube; the increased resistance in the variable period was but 50 per cent. against 600 per cent. for the iron tube, or only one-twelfth of the additional resistance caused by the tube. These wires were replaced by galvanised iron wire, which prevented magnetic contact, and the variable resistance became much less, and when these were replaced by numerous fine iron wires the effect was reduced to the minimum found, or only 20 per cent. increased resistance in the variable period, or 30 times less than that of a solid iron tube of much less iron.

It is therefore evident that the circular magnetism plays an important *rôle*, and that most fortunately our cable manufacturers (without knowing the immense reaction which would be produced by a continuous sheath of iron) have constructed our cables with a protection of iron divided into several iron wires instead of a continuous iron sheath; there are, however, many telegraph lines which in passing through tunnels use a continuous iron tube as the protection, and therefore such lines must feel all the deleterious effects that I have shown to be caused by the reaction of circular magnetism.

Influence of Copper and Iron Cores upon the Induction and Resistance of Coils.

It is well known that a coil of wire has a higher self-induction than the same wire in a single loop, and that the coil has a still higher induction when we introduce an iron core. I have made, however, a series of experiments in order to measure the influence of a core upon the resistance in the variable period, and also note the influence exerted by the induced or eddy currents circulating in the core.

Table IV. shows some comparative results.

A helix was formed of an insulated silk-covered copper wire of 24 single layers, having an interior diameter of 2 cm., the object being to form a coil having as little mutual induction as possible, but which would be readily acted upon by any core of metal introduced; and in order to measure the high forces obtained an induction balance of great power and range was used, the method, however, being the same as that already described.

The helix alone showed an induction value for its extra currents of 460, and a feeble increased resistance in the variable period of but 10 per cent.; if we now introduce a core of solid copper of 1·75 cm. diameter and 5 cm. long, a great change takes place both in the force of the extra currents and the resistance in the variable period; the extra currents fall in value from 460 to 352, whilst the

* Read at the Royal Society, May 27, 1886.

Digitized by Google

extra resistance is increased to 52 per cent. above that of the stable period. We have here a double and contrary effect; the reduction of the force of the extra currents and the increase in the resistance cannot be due to the magnetic nature of copper, but must be due to the induced or so-called "Foucault currents" circulating in the core. To prove this the core was replaced by another similar in every respect, but cut longitudinally to its centre; the currents now ceased to circulate, and the copper core had not the slightest effect either on the extra currents or the variable resistance.

This is is shown in the table, where for greater precaution a core of insulated copper wires replaced the solid core. Evidently the induced current in the core was the cause of the extra resistance; work was done by the primary current, and a loss of energy at the expense of the electromotive force of the extra currents, but in doing this work a resistance was produced which was no doubt caused by the currents circulating in the core. These currents required time, passing through the variable stage and thus producing from their electro-magnetic inertia an equivalent reaction and electro-magnetic inertia in the primary coil itself. That this inertia is due to the electro-magnetic character of the current and not to an electric current considered apart, is proved by the fact (which I have verified) that when we coil a wire into a coil of several superposed layers, its electro-magnetic reactions introduce a measurable resistance in the variable period precisely similar, though feebler, than that which would be produced by the reaction on the conductor of a magnetic body such as iron.

TABLE IV.

Helix formed of insulated copper wire, 1·50 metre in length, 2 cm. diameter, and 24 turns.	Comparative force of the extra currents.	Resistance in ohms, stable period.	Resistance in ohms, variable period.	Percentage of increased resistance in variable period.	Absolute increase of resistance in ohms.
Helix alone.....	460	0·02632	0·02896	10	0 00264
Same with a core of solid copper..	352	0·02632	0·04013	52	0·01381
Same with a core of insulated copper wire	460	0·02632	0 02896	10	0·00264
Same with a core of solid soft iron	2338	0 02632	0·09870	275	0·07238
Same with a core of 445 separate fine iron wires, each 0·25 mm. diameter.....	5360	0·02632	0·04448	69	0·01816
Same with a core of silk-covered fine insulated iron wires	5820	0 02632	0·04075	55	0·01443

The effect of a solid iron core and a bundle of iron wires on the increase of the force of the extra currents is well known, but the table shows an interesting result as to their effects on the variable resistance; the solid iron core shows a very high force of extra currents produced by its magnetic reaction on the wires of the helix, the resistance in the variable period has increased 275 per cent., and its extra currents are extremely high, as we should expect. Now, if the extra resistance is due to magnetic reaction alone it should increase when we are enabled to increase this reaction, but if it is due in greater part to the electro-magnetic inertia of electric currents circulating in the bar, then by preventing these currents from being formed (as we did in the case of copper), we should greatly reduce the extra resistance. This proved to be the case, for on replacing the solid iron core by a bundle of fine iron wires the force of the extra currents rose from 2,338 to 5,360, or more than double the force of that produced by a solid bar, whilst the resistance in the variable period fell from 275 to but 69 per cent.

It is well known that a bundle of fine wires magnetises quicker than a solid bar, and this may have had its effect, although not more important than the suppression of the eddy currents, as the latter may be the cause of the former. The table shows that where we have suppressed these currents as far as possible by introducing a core of insulated wires containing less iron than in the previous experiment, but fully insured against eddy currents, the induction was the highest and the resistance the lowest yet found for a helix containing an iron core. The experiment proves to my mind that the extra resistance found in the three last experiments is due both to the electro-magnetic inertia of the eddy currents, and the inertia of the magnetic molecules of iron.

The experiments related in this paper have been most carefully made and verified, and from the ease and certain action as well as the invariable results obtained by the method which I have described, they should be easy to repeat by others.

If we regard the whole of these researches we cannot fail to notice certain important laws which act in the greater portion of them. I have shown:—1st. That the contiguous portions of the same current react upon each other in the interior of its own portion of the conductor similar to their known exterior reactions on separate portions of the same conductor. 2nd. That the coefficient of mutual induction is less in iron than copper wires, but that their coefficient is the same when the conductor is in the form of a ribbon. 3rd. That the inductive capacity of different metals depends on their specific resistance, on their electro-magnetic capacity for circular magnetism, and on the geometrical form of their conductors. 4th. That the inductive capacity of a conductor of magnetic metal is dependent upon the formation of circular magnetism and not upon its internal magnetic permeability. 5th. That a magnetic metal can be rendered equally free from circular magnetism as the non-magnetic metals. 6th. That we have experimental evidence of electro-magnetic inertia and the deleterious effects of eddy currents in the cores of electro-magnets.

In addition to the above effects, we have the discovery of a large increase in the ohmic resistance during the variable period, allowing us to demonstrate and measure the gradual rise of an electric current in its conductor.

In conclusion, I desire to express my warmest thanks to Lord Rayleigh, Mr. F. L. Pope, Prof. Forbes, Dr. Hopkinson, Mr. W. H. Preece, Dr. Fleming, Mr. FitzGerald, Prof. Silvanus Thompson, and Prof. Ayrton, for the important theoretical contributions they gave on the discussion of my first paper. Mr. W. H. Preece, electrician of the Post Office, not only gave information of great practical value, but has kindly supplied me with the wires used in these experiments. The discussion proved the necessity of the researches which I have undertaken, and the importance of an experimental determination of the self-induction of an electric current in relation to the nature and form of its conductor.

PHYSICAL SOCIETY.—June 10th.

ELECTRIC LIGHT FIRE DAMP INDICATOR.

At the last meeting of the above society the following paper on this subject was read by Messrs. Walter Emmott and William Ackroyd:—

The Royal Commission on Accidents in Mines point out in their recently issued report a serious objection to the use of the electric light in mines, notwithstanding its many other great advantages in that the light of an incandescent lamp being produced within a vacuum cannot admit of any device for the indication of fire damp, such as is employed in the Davy for example. This difficulty was experienced by one of us in the course of an installation of the electric light in the Lofthouse Pit, Wyke, Yorks., in the summer of 1885, and we have since made a series of experiments with the object of devising a method of making the electric light an indicator of fire damp. The apparatus placed before the Physical Society is the outcome of our work. It consists of two incandescent lamps, one with white glass and the other with red, and other necessary adjuncts, such that in an ordinary atmosphere the white incandescent lamp alone shines, but in fire damp the white lamp goes out and the red one begins to emit its light. This is effected as follows:

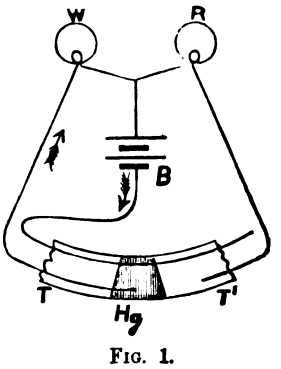


FIG. 1.

A porous pot of unglazed hard baked porcelain is joined by air tight connections to a tube, a portion of which is represented by T T¹ (Fig. 1). This tube is of such an internal diameter that it will readily admit of being sealed with a small quantity of mercury, H *g*. A platinum wire runs the whole length of the tube, and is connected with one of the poles of the battery B, or other source of electricity. Two other platinum wires in the tube run parallel with this for part of the way, as in Fig. 1, and

Digitized by Google

each is connected with a lamp. The lamps W and R are joined, and a branch wire connects them to the other pole of the battery. In Fig. 1 the current is represented as flowing through W; when from diffusion in an atmosphere of fire damp the conducting plug H g is driven up to T^1 the current will flow through R, and the red light may then be taken to indicate the presence of fire damp.

The wires being within the tube, one or other of the lamps must always be shining so long as there is a current, whether the apparatus be in an atmosphere of fire damp choke damp, or air; and to prevent the mercury being driven out of the tube by too much pressure, bulbs are arranged on either side, as in Fig. 2, which presents a diagrammatic view of the apparatus. We have found an internal diameter of tubing of about 3mm. best adapted for ensuring easy mobility of the mercury. The presence of the wires within the tube has interfered with the perfection of the seal; this we have overcome by the introduction of a little concentrated sulphuric acid, which also serves the purpose of preventing sparking and of lubricating the interior. The use of sulphuric acid necessitates the addition of dessicators a and b (Fig. 2) to each end of the tube, but in cases where it

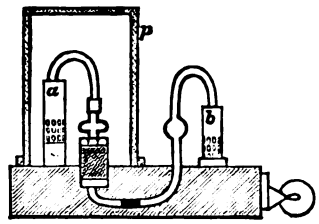

FIG. 2.

p Porous pot. a and b Dessicating tubes.

has been found advisable not to use sulphuric acid, both the acid and the dessicators have been dispensed with by slightly modifying the arrangement of the wires at the lower part of the tube. With this form of apparatus we are readily able to detect the presence of 5 per cent. of coal gas in a mixture of this gas with air, and with a mercury seal of less weight and closer proximity of the wires at T and T^1 (Fig. 1) it appears possible to get any required degree of sensitiveness. It is proposed to have the apparatus fixed in the main roads and hauling roads in pit installations.

COMPANIES' MEETINGS.

Australasian Electric Light, Power, and Storage Company (Limited).

The fourth ordinary general meeting of this Company was held at the offices, 41, Coleman-street, on the 11th inst., under the presidency of Mr. Philip Falk.

The SECRETARY (Mr. J. H. Duncan, F.C.A.), read the notice convening the meeting, and the report of the Directors was taken as read. The balance-sheet was submitted as at Dec. 31 last, and the profit and loss account for the 18 months from 1st July, 1884, to the same date. The profit and loss account, it was stated, "has been divided into two, with the view of clearing the trading account (proper) of sundry charges, such as the New Zealand loss, arising from the early history of the Company, and an analysis is likewise submitted, with the view of dividing up the account into the three successive half years embraced in the period since the former report." The result of this analysis was as follows:—Loss for the half year ended December, 1884, £2,474; for the half ended June, 1885, £1,685; and for the half year ended December, 1885, £111. The report also stated:—"Since last reporting to the shareholders the prospects of electric lighting in the colonies have become of a decidedly more settled character. What seemed at one time a likelihood of the Electric Lighting Act of the Home Parliament being adopted in Australia has passed away in consequence of that Act having admittedly proved in England a dead letter. Private enterprise in electric lighting, therefore, if not yet clothed with those privileges which will sooner or later become necessary, has not been hampered as it has been in this country. Mr. Want (till recently a Director of the Company) having occasion on other business to visit the colonies, courteously offered to confer with the General Manager in Australia, and to render any assistance in his power, and the Directors consider that thanks are due to Mr. Want in the matter. Since the date of the last report, two Directors, Mr. Randolph C. Want and General Meade Hamilton, have retired, and the Directors have elected Mr. B. H. Van Tromp and Mr. Aymor H. Sanderson, as members of the Board."

The CHAIRMAN, in moving the adoption of the report and balance-sheet, said that his remarks would necessarily be very short, for they had to get this meeting over rather early, for this reason: that the Edison Indian and Colonial Company were holding a meeting that day at four o'clock, and they would want to know whether the shareholders of the Australasian Company had ratified the agreement proposed between the two, and to which he would refer later on. His colleagues and himself confessed that they were disheartened, and at the same time dissatisfied, with the result of their working for the last eighteen months. They had tried as far as they could to reduce every expenditure on this side as well as in the colony, and, as the shareholders would see, the loss for the past six months was comparatively infinitesimal—only £111; but they had expected to do better than this. The Directors, however, believed that at the next meeting they would be able to show that, by cutting down the expenditure at both ends, and by carefully fostering all the work they could obtain on the other side they would be able to show a small profit. As far as he was able to see he thought they were just turning the corner. If the times in Australia had been better they would have had more public support. What they had been anxious about was that they should sublet, so to speak, to companies on the other side, their patents, &c., the value of which, he might observe, had of late been very materially improved. For one reason and another, things throughout the colonies had been in such a dreadful state in the last few years that they could not get people to entertain any proposal in that direction. If, however, they could only wait a little longer he felt satisfied that such a period would arrive, and they would take advantage of it. He did not know that it would serve any particular purpose to weary them with a recital of the non-success of the Company in the past, but it would be some satisfaction to him—and he was sure it would be to his colleagues, and it was only due to the shareholders—to state some of the causes why they had not been able to make greater progress. There were a good many reasons which he could assign for it, but among others he might mention that they began life, so to speak, with great expectations. They went to a new field, and they expected that they would be able to make a very handsome thing out of the enterprise; the expenses on both sides—more especially in the colonies—were very large; the work they had done was of a tentative nature; the opposition they had to meet with on all hands was very great, the various companies all striking out with the view of showing that their system was the best. That system, had, so to speak, crippled the Company. They could not get people in the colonies to take the matter up. By working against this unwholesome competition a very large amount of their legitimate capital had, up to a certain date, been constantly dropping off. The next thing was that the times had been against them, both here and in the colonies. As the shareholders knew, all the electric lighting companies in this country had suffered, and this state of things had naturally reacted on the colonies, for whatever occurred here was cabled out to the colonies, where people would have nothing to do with anything that was not thoroughly established. If they would consider all these difficulties he believed they would come to the conclusion that the Directors had—in the interests of the shareholders and of themselves—done the utmost they possibly could in the circumstances that had existed. If that were the view of the shareholders, the Directors would be encouraged to go on on with their efforts. If the shareholders should think differently it would kill whatever little ardour there was left in the Directors. A large expenditure was entered on in the past, because it was believed by the people who had the management on the other side that it was only by that means—by having a large quantity of plant, great premises, and a number of engineers running all over Australia, trying to outdo everyone else—that the Company could become successful; but all this meant a large expenditure of capital, and in the colonies everything happened to be twice as dear as in this country. Believing in their officers, in whom every trust was reposed, all this outlay was sanctioned. In domestic affairs, when prosperity prevailed, the expenditure was heavy in a variety of ways, but when bad times came they had to look around and see where retrenchment could be exercised. It was much the same with companies, and their Company had gone through such an experience, to their cost. It was, however, so far he could see, utterly impossible for them to have acted differently, unless they could have foreseen things miraculously. They had been disappointed, it was true, but that did not say that better times were not in store for them, more especially under existing circumstances. If figures showed anything, they demonstrated beyond a doubt that the Company were now, at all events, on the high road to see their way. [A Voice: "Bosh!"] That might be the opinion of one gentleman who had always favoured them with his presence at these meetings. He only hoped that they would see him among them from year to year, and that he would have occasion to reverse his opinions. He (the Chairman) could assure him that if he were placed, as they were at the Board, in a position to watch the business closely, he would come to a different conclusion. As the shareholders were aware, the Company were partners in the Australian Electric Company (Limited), of Melbourne, in which they were the largest shareholders. In fact, as would be seen from the balance-sheet, they held 18,000 shares in that company, which had already completed their lighting station, and they were now beginning to pay. They were also making strenuous efforts to extend that lighting station, and they themselves were hoping to reap some benefit at all events from the dividend which the other company might declare. In amalgamating with that company, or affiliating it with their own, they had got rid of a great opponent, and now that the thing had been worked round pretty well, they saw already that there was a dividend in the case of the other company, in which case their own Company would benefit to the extent of their holding. They were now proposing a very important arrangement with the Edison Company, as referred to in the report. With reference to the inquiry that took place last year into the affairs of the Company, when the committee finished their investigation they came to the conclusion—as already anticipated by the Board—that every effort should be made to place the Company, both here and in the colonies, on the basis of the smallest possible expense. That had been done. The hands of the Directors had been strengthened by the fact that one of the members of the committee had been appointed a Director, and had gone thoroughly into the position of the Company. That gentlemen had worked with the other members of the Board in harmony during the whole of the time since his appointment.

Digitized by Google

They had given that gentleman every possible opportunity to try and find out if there was any hitch anywhere, so that he might indicate to the committee or the shareholders anything which he might feel required to be remedied. Mr. Van Tromp (the gentleman referred to) was now present, and might say a few words; and if he could mention anything which might bring about an improvement in the position of their affairs, such information would be gratefully received by the Directors generally. It was expected that if the arrangement with the Edison Company were ratified, Major Flood Page would probably join the Board of the Australasian Company. Major Page had visited Australia on behalf of the Edison Company, and had valuable information that would no doubt be to the advantage of the Company. He would not detain them any longer, though he had several notes before him, and he would conclude by moving the following resolution: "That the report of the Directors now submitted, with the accounts thereto annexed, be and it is hereby received and adopted."

Mr. B. H. VAN TROMP, in seconding the motion, said that when he first went on the Board, having regard to the inquiries that had been made by the committee, to the minute and close examination which the committee—including himself— had made into the previous operations of the Board, and their conduct in carrying on the affairs of the Company, he was under the impression that there had been grossly mistaken management in some respects, and expenditure which might have been avoided, but certainly he had not come on the Board with the impression that any gentleman had done anything that was dishonourable, and after working with them eighteen months that impression was confirmed. The Directors were men of honour and gentlemen, who, to the best of their belief, had conducted the Company for the benefit of the shareholders. It was not for men to command success, but he believed that the Directors had deserved it. During the last eighteen months he had attended, with one exception, every Board meeting of the Company, and also the committee meetings, and he ventured to say that if he had known the enormous labour and anxiety which a seat at the Board entailed on any man having to earn his living, as he had, as a professional man, he would have hesitated very much before accepting the position. Nothing relating to the Company had come from the colonies which he had not seen. The able Secretary had assisted the Directors to the very best of his great ability in carrying on the affairs of the Company, not only as regarded this country but on the other side. The Directors thought that in carrying out the proposed arrangement with the Edison Company they had, as it were, put on the crowning arch of the building, and it might possibly lead to a success in Australia which at that moment one could scarcely imagine as possible. If any shareholder were offered 20s. a share, with the liability of the call of £1 per share, he would not advise him to sell. That was his view of the position of the Company. The Directors were prepared to answer fairly, and without the slightest reservation, any question which might be put to them concerning the accounts or any of the affairs of the Company. He would not refer more to the Edison Company, as that matter would be dealt with afterwards; but he asked them to believe that the Board had done, and would do, if they were re-elected, the very best they could for the shareholders and themselves as shareholders; and they confidently believed that they would be able yet to make the Company a dividend paying company. They did take some credit to themselves for having carried on the Company for 18 months without asking the shareholders for one shilling. The Board had made themselves responsible for advances, but they were anxious to see whether, in alliance with the Edison Company, they might not be able to avoid calling up the whole of the uncalled sum. He asked the shareholders for their cordial assistance, without which no Board could make a company a success.

Mr. BENJAMIN KISCH said that having within the last 18 months had an opportunity of looking into the prospects of the Company, he would like—he admitted it was on imperfect knowledge—to confirm all that Mr. Van Tromp had said. Gentlemen present would probably remember that he (the speaker) was one of those who served on the committee who investigated the affairs of the Company. He and all the other members of the committee approached the subject with quite open minds, and when they last met there were a considerable number of persons who thought that the wiser course would be for them to save what they had and wind up the Company. That was an opinion very generally expressed. It was one on which at the time he could not express any view, as he had not sufficient knowledge of the affairs of the Company, but after the opportunities which he had had, in common with the other gentlemen who investigated the affairs of the Company, he had come very decidedly to the same conclusion as the Chairman and Mr. Van Tromp—that it would be an exceedingly unwise thing for them now to wind up. He did not consider that they were now walking on their last plank; on the contrary, if electric lighting was to revive and to become anything in the future, he should think the chances of Australia ought to be at least as good, and for many reasons better, than in many other parts of the world. No doubt, in consequence of past misfortunes, their capital account was overloaded, but whether they wrote it down or not, they knew that a large amount of it was practically written off. If in the future, as they had every reason to hope, some dividend might be able to be declared, he should think it would be a matter upon which they might congratulate themselves, even if the dividends were small. Certainly their prospects at the present moment would not warrant them in winding up, and he hoped they had now heard of that suggestion for the last time.

Mr. W. T. MORRISON said that they all knew that the adoption of the electric light had been of slow growth, but from evidence around them he thought that their Company, like some of the others, would do better in the future than in the past. He agreed with the last speaker that it would be most unwise to wind up; and if they were to take that step they would have to call up everything. He thought that the best plan was to leave matters in the hands of the Board, and leave them to do the best they could for the Company. They had heard from the Chairman and Mr. Van Tromp that their prospects were better than in the past, and judging from the prospects of electric lighting generally, he thought they might hope for something better than they had at present had from Australia.

A SHAREHOLDER asked what was the actual result of the last call.

The SECRETARY: £23,200 out of £24,000.

A SHAREHOLDER said that during a recent visit to the colonies he had had every opportunity of seeing in Australia what the Company were doing, and he had bought 100 shares. In his opinion a great deal depended on the amalgamation with the Edison Company, and in that case he believed that there was a possibility of the Company at some time or other paying a dividend.

After a few observations from Mr. PEARSON, who had served on the committee, and who said he thought that matters should be left in the hands of the Directors,

The CHAIRMAN put the motion and it was carried *nem. con.*

Mr. PEEK then proposed the re-election of all the Directors—Messrs. J. J. Cater, Latimer Clark, C.E., Philip Falk, Aymor H. Sanderson, and B. H. Van Tromp. He thought that, considering the undertaking had been such an unfortunate affair—in fact, like almost every electric company—the Directors had shown a vast amount of pluck, energy, and courage in trying to pull the shareholders through. When there was some discussion as to whether they should be replaced by others or whether the Company should be wound up, he strongly supported them because he saw that they were determined, if they could, to bring the Company round; and with the valuable assistance of Mr. Van Tromp he was sure that they had been redoubling their exertions. If there were a chance of pulling the Company round and making it a dividend paying concern they would do it, and, as far as he could see, there seemed to be hope that they would pull through. [Mr. Van Tromp: Hear, hear.] He knew that one or two gentlemen on the Board were quite convinced that the Company had turned the corner, and by the skill and energy of the Directors—who as men of honour were bound to do their utmost to make the concern a success—he was in hopes that they would become a dividend-paying company.

Mr. MORRISON seconded the motion, which was carried unanimously.

The CHAIRMAN, on behalf of his colleagues and himself, thanked the shareholders for their confidence, and assured them that the Board would endeavour in the future, as in the past, to bring the Company through its difficulties.

Mr. PEARSON next proposed the re-election of the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., at a remuneration of thirty guineas.

The motion having been seconded, some discussion ensued as to the amount of the fee, it being contended that in the present position of the Company every penny that could be saved ought to be saved. Ultimately,

On the motion of Mr. MORRISON, seconded by Mr. STOBART, an amendment was passed, reducing the amount to twenty guineas.

An extraordinary general meeting was then held, to consider the approval and ratification of an indenture, dated the 20th ult., made between the Edison Indian and Colonial Electric Company (Limited) of the first part, Thomas Alva Edison, of Menlo Park, New Jersey, United States of America, electrical engineer, of the second part, and the Australasian Company of the third part; and of a series of resolutions for giving effect thereto.

The CHAIRMAN proposed the first resolution, approving and ratifying the indenture.

Mr. CATER seconded the motion.

A SHAREHOLDER asked what the advantages of the arrangement were.

The SECRETARY stated that by the arrangement proposed the Company would acquire the whole of the patents (with all improvements up to a certain date) of the other company, who had hitherto been their competitors. Those patents also covered India and the Cape, though for a time possibly they would only be able to do an indirect business in those places. In connection with that matter there was, perhaps, some importance to be attached to the success which the Edison Company had recently obtained in establishing their patents. Probably they would derive benefit from that in the shape of royalties in India and the Cape. They would also have from the other company their book debts, amounting nominally to £2,547, and their plant, which stood, at cost price, at £4,925. They themselves, however, did not put those values on those items. Against these advantages they would allot to the Edison Company 34,513 ordinary shares of £1 each, being one share for each share the Edison Company had in issue. These shares, in case of a distribution of assets, would only rank alongside the existing shares of the Company, which were called "original shares," for one-half their nominal value, or £17,256. 10s. Therefore, in the event of a distribution of assets that was the amount they would have paid for the patents, the book debts, and plant of the Edison Company. On the other hand, in order to facilitate the amalgamation they were to receive from the vendors of the company £18,145 in fully-paid ordinary shares; so, in point of fact, it was really the vendors who were purchasing the arrangement for the Company, and not the Company themselves. Moreover, the existing, or original, shares were to take 1 per cent. dividend out of the profits of the Company before the ordinary shares given to the Edison Company received anything; and, after that, the original and the ordinary shares would participate equally up to 10 per cent. for dividends. After that rate had been paid, the 34,513 deferred shares which they were also going to give to the Edison Company would begin to rank. In reply to a question, he stated that before they paid any dividend the Directors had the right to lay aside a reserve fund. Continuing, he said that the voting power had had to be changed, but it had been reserved

Digitized by Google

very much in the hands of the original shareholders. They would have five votes for every £5 share, while the ordinary share and every ten deferred shares conferred one vote each. In addition to the £18,145 in shares which the vendors had relinquished for the purpose of the arrangement, there was a sum of £3,010 relinquished of the founders' shares, leaving only a nominal amount for founders' shares. There were two points stipulated for by the Edison Company. One was that Mr. Edison should reserve the right to an exclusive license for the application of his patents to locomotives on railways, tramways, or common roads. That was a stipulation made by Mr. Edison in selling the patents to the Indian and Colonial Company. The other stipulation was that in case anything should happen to make the Australasian Company wind up before March 1, 1889, such of the Edison patents as should not have been dealt with should revert to Mr. Edison. That, however, was quite a nominal condition. They would have to pay certain trade debts of the Edison Company on this side amounting to £163.

In reply to Mr. Kisch,

The SECRETARY stated that the founders' shares would take two-fifths of the surplus profits after a dividend of 10 per cent. had been paid and a reserve fund provided for. By the proposed arrangement the two-fifths surplus profits would be divided among the 2,000 shares which would remain in the hands of the founders, and the 3,000 which would be held by trustees for the Company.

The CHAIRMAN, in answer to a question, said that the Edison Company were the only competing company in Australia of which they were aware.

The SECRETARY, however, stated that the Gülcher Company had done a little in New Zealand.

The CHAIRMAN, in further reply, said that the committee that was appointed last year agreed with the Directors that it would be a step in the right direction if they were to take over the business of the Edison Company. The harm done to them by that company was in constantly competing against them. If the arrangement did no more than remove an obstacle of that description to their progress they would be in a better position by effecting it.

Mr. STEPHENS spoke in favour of the arrangement, and

Mr. MORRISON said he thought there could be no doubt as to the advantage of the proposal.

The motion was then carried, and the other resolutions were also severally agreed to.

The CHAIRMAN having intimated that a confirmatory meeting would have to be held in about a fortnight,

A resolution was passed thanking Mr. Want for the assistance he had rendered the Company during his late visit to Australia.

A vote of thanks to the Chairman and Directors was afterwards passed, and the meeting then separated.

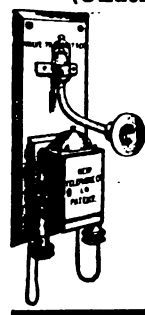
THE BERNSTEIN ELECTRIC LAMP CO.,
(LIMITED).
9a, COMMERCIAL ROAD, PIMLICO, S.W.
Manufacturers of the Bernstein Incandescent Lamp. Lamps from 5 to 100 candle-power. Lamps made to fit any kind of Holder already in use.
The Company have acquired the Patent Right of the Bernstein Lamp for England and Colonies, Belgium, Italy, Russia, Spain, and Portugal, Sweden and Denmark Particulars and Price Lists on Application

GANZ and CO., Buda Pest,
4, WESTMINSTER CHAMBERS, S.W
Manufacturers of
Déry, Blathy, & Zipernowsky's Secondary Transformers.
Electric Light Installations carried out.

WILLIAM BANKS,
ELECTRICIAN,
CONTRACTOR for ELECTRIC LIGHTING and ALL KINDS of ELECTRICAL ENGINEERING,
32, CORPORATION STREET, BOLTON.
Telegrams, "BANKS, BOLTON." Works, BARK STREET.

NEW TELEPHONE CO., LIMITED
(Under License from the Postmaster-General).



The above Company is SELLING TELEPHONES to the Public outright. These Telephones are Manufactured under the Patents of Professor Silvanus P. Thompson and others, and are now in successful operation in leading towns in the kingdom.
The Company will give a formal guarantee to any purchaser requiring the same against any claims which may be made by trade rivals for alleged infringements.
This Company is now receiving applications for the establishment of local exchanges.
For full particulars apply to the Secretary,
NEW TELEPHONE COMPANY, LTD.
4, Great Winchester Street, London, E.C.

THIRD EDITION. Price 7s. 6d.
(POCKET SIZE. LEATHER.)
An Electrical Pocket-Book
OF
ELECTRICAL RULES AND TABLES,
BY
JOHN MUNRO, C.E.,
AND
ANDREW JAMIESON, F.R.S.E., C.E., M.S.T.E.
WITH NUMEROUS DIAGRAMS.
GENERAL CONTENTS.—Units; Measures; Testing; Conductors; Dielectrics; Submarine Cables; Telegraphy; Electro-Chemistry and Metallurgy; Batteries; Dynamos and Motors; Electric Lighting; Miscellaneous Recipes.
"WONDERFULLY PERFECT. . . . Worthy of all the commendation we can give it."—*Electrician.*
"The STERLING VALUE of Messrs. Munro and Jamieson's Pocket Book. . . . . carried out in a manner which does the greatest credit to the authors."—*Electrical Review.*
"A veritable Pocket Companion."—*Telegraphist.*
"Furnished with a capital Index. . . . Well adapted for consulting at any moment, and under almost any circumstances."—*Scottish Engineer.*
London: CHARLES GRIFFIN & CO., Exeter-street, Strand.

NOTES.

TELEGRAPH CABLE REPAIRED.—The cable of the Paris and New York Telegraph Company is repaired.

ALGIERS.—Authority has been given for the construction of the first subterranean telegraphic line in this French colony.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 18th inst. amounted to £2,677.

REDUCING RATES.—Our advertising columns give particulars of the reduced rates over the lines of the Eastern and Eastern Extension Telegraph Companies to be applied from the 1st proximo.

CHELSEA.—On another page we discuss the provisional order, granted this year by the Board of Trade, authorising the Chelsea Electricity Supply Company to supply electricity within the parish of Chelsea.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th inst. are £2,460, as compared with £3,050 in the corresponding period of 1885.

VICTORIA.—Allowing for the difference of time, the telegraphic announcement of 69 words by which the Governor of Victoria announced the opening of the exhibition at Melbourne was transmitted to London in about 23 minutes.

THE FRENCH TELEGRAPHIC SERVICE.—Our contemporary *Electricité* is very hard upon the service, stating that the management is in a state of "inferiority" in comparison with that of any other country in Europe or America.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 18th inst. were £2,110, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE GRAPHOPHONE COMPANY.—This company, owning the patents of Mr. Bell's newest invention in telephones, has its legal *habitat* in Alexandria, Va., having been chartered in that city under the name of the Volta Graphophone Company.

THE FIRST ELECTRIC-LIGHTED CITY.—The first city in Europe where electricity has been entirely substituted for gas for street lighting is Hernosand, in Sweden. The motive power is water, which is very plentiful there, rendering the electric light cheaper than gas.

THE SOCIETY OF TELEGRAPH-ENGINEERS.—Prof. Hughes, F.R.S., president of this society, and Mrs. Hughes have invited the members to a *conversazione* at the Royal Institute of Painters in Water Colours, 191, Piccadilly, on the evening of Tuesday, 29th inst., from 9 to 12.

WEST AFRICA.—The West African Telegraph Company has opened a station at Bathurst, and on Sunday received a telegram thence stating that as Sir Samuel Rowe, the Governor of Sierra Leone, would leave for England on Monday, Captain Hay had gone from Bathurst to take charge.

THE EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—This company notify that the coupons on their Five per Cent. Mortgage Debentures due on 1st July will be paid on and after that date by Messrs. Barclay, Bevan, and Co., Lombard-street, London, E.C. Coupons must be left three clear days for examination.

EXAMINERS IN ELECTRICITY.—At the recent examination of the London University for the degree of Doctor of Science in the subject of electricity the candidates were asked to describe "Wilmshurst's influencing (*sic*) machine." We have heard of influence machines, and we have the honour of knowing Mr. Wimshurst, but what is this new horror?

SMALL INDUSTRIES EXHIBITION, STOCKHOLM.—Group IV. of an exhibition to be opened at the Utställningskomiterade, Stockholm Handtverksföreningenshus, includes machines and apparatus of small size for the production and application of electricity; but no object must require more than 2 square metres of ground space, for which no rent is charged.

ELECTRICITY AND GAS COMPANIES.—A Bill will probably be favourably reported to the Massachusetts Legislature relative to the extension of the charters of the gas companies of the State permitting them to distribute electric currents. The broad powers granted will open the field of the distributing of power by electric motors, or the furnishing of currents to home railroads for the purpose of propulsion.

EASTERN EXTENSION COMPANY.—The Eastern Extension, Australasia, and China Telegraph Company states that the coupons due 1st of July on the Five per Cent. Australian Government Subsidy Debentures will be paid by Messrs. Barclay, Bevan, and Co. Coupons must be left three clear days for examination. The company announce an interim dividend for the quarter ended March 31st of 2s. 6d. per share, tax free, payable on July 15th.

VAN RYSSELBERGHE.—*Le Globe Illustrè* of June 13, an illustrated paper published at Brussels, gives a short biography of M. Van Rysselberghe, with portrait. With regard to his system of telephony upon the telegraph wires, we are told that the first official experiments were made on the 4th March, 1882, between Ostend and Brussels, and that on the 16th and 17th March the experiments were between Paris and Brussels. The system has been shown by numerous experiments to be successful.

ORIGIN OF ELECTRICITY IN STORMS.—M. Colladon, in a paper to the Academié des Science, suggests that the electricity so vividly illustrated by thunderstorms is generated principally by friction of air and water vapour. During a thunderstorm the rain drops formed in the storm cloud descend vertically to the earth, causing a partial vacuum, which is replaced by air drawn in laterally and from upper layers. The friction caused by this movement is the principal cause of the generation of electricity.

THE TYPO TELEGRAPH.—This new invention is now being tried by the French Minister des Postes et des Télégraphes, to whom it has been submitted by M. Etienne de Fedor. It is intended to devote it chiefly to press messages. The article of a journal which is to be forwarded by telegraph to another journal is first set up in ordinary type in a column and then stereotyped. The block is afterwards sent to the telegraph office, and serves as original of the message. M. Fedor claims that the rapidity of the transmission may reach about 1,200 letters per minute, or about 14,000 words per hour.

THE EASTERN TELEGRAPH COMPANY.—This Company announce that, subject to the final audit, the accounts show, after placing £70,000 to reserve fund, a balance available for dividend sufficient to pay at the general meeting on 15th July next the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the Preference Shares, and a final dividend of 2s. 6d. per share, with a bonus of 1s. per share, free of income tax, on the Ordinary Shares, making, with previous payments on account, a total dividend of 6 per cent. on those shares for the year ending 31st March, 1886, and carrying forward a balance of about £4,000.

ACCIDENTS FROM LIGHTNING.—Dr. Andries, having circulated that accidents from lightning have increased from three to five fold during the last 50 years, finds that the causes which have been assigned for the phenomenon do not account for all. He regards the main cause as lying in the

Digitized by Google

enormous increase in manufactories, locomotives, &c., which fill the air with smoke, steam, and particles of dust of all kinds, while the increased populations contribute their share to the impurity of the atmosphere. His own experiments, and those of others, have shown that all the electrical phenomena of the air increase in intensity with the increase of dust in it.

ELECTRIC LIGHT IN AMERICA.—The development of electric lighting in the United States is rapid and continuous, as may be gathered from the fact that the Edison system alone comprises forty-one central stations, with a total capacity of supplying 100,000 lamps. Thirty-two of these stations are now actually at work, lighting 85,725 incandescent lamps. Adding to these the lamps to be lighted very shortly at stations now in course of construction, the total installation of Edison lamps in the United States will amount to 127,425. This is quite independent of the other systems in use. In France the total number of lamps of every kind now in operation is only 55,000.

AN ENTERPRISING HOUSE.—MM. Sautter, Lemonnier and Company have already installed in France 1,357 arc and 1,613 incandescent lamps, in addition to 288 arc and 523 incandescent lamps in foreign countries. Of these, England absorbs 88, the colonies 49, while 43 are in India, and 28 in Italy. The photo-electrical apparatus for naval and military purposes constructed by this firm is even more widely and extensively distributed, being adopted by every country in Europe, as well as by Japan and the United States. The total number of Gramme machines employed in connection with this apparatus amounts to 587, requiring a motive force equal to 3,167 horse-power.

THE ELECTRIC LIGHT AT COLCHESTER.—At a special meeting of the Colchester Town Council, held last week, the following resolution was passed:—"Resolved unanimously, that this Council hereby sanctions the transfer from the South-Eastern Electric (Brush) Lighting and Power Company to the Colchester Electric Light and Power Company, of the Colchester Electric Light License, 1884." It is to be hoped that under whatever arrangement may be come to between the old and the new company, Colchester, which was the first town in England, or, for the matter of that, in the world, that adopted the electric light for public lighting, will be better served in this respect than it seems hitherto to have been.

CABLE TO BATHURST.—We are informed by the India Rubber, Gutta Percha, and Telegraph Works Company that the cables from Sénégal, from the Cape Verd Islands and from Bolama have been successfully completed to Bathurst, and that their ships the "Dacia" and "Buccaneer" have left that place for Siérra Leone to complete the Konakri-Siérra Leone section. The West African Telegraph Company's station at Bathurst has been opened to the public, and messages can now be sent to that place, addressed, *viâ* Cadiz, from the offices of the Direct Spanish Telegraph Company, the Eastern Telegraph Company, and the Submarine Telegraph Company, or from any postal telegraph station, the tariff being 5s. 11d. per word. This important advantage will be, we doubt not, highly appreciated by the telegraphing public.

SENDING PICTURES BY TELEGRAPH.—The *British Journal of Photography* mentions the fact that a patent for sending pictures by the telegraph wire has recently been taken out. Photography is an essential in the process. Mr. Grimnill, of Kirkmaiden, Wigton, has patented a system of photo-telegraphy, of which the following is a description: The picture is projected in sections, as it were, upon selenium cell in the circuit of the wires, and so causes a greater or less number of subsidiary currents to be switched on to an incandescent lamp at the receiving end, the brightness of the light following the intensity of the spot of picture thrown upon the selenium. Here the photography is of service. The lamp is focused on to a plate, and its varying intensities fixed upon the photographic tablet. The idea may be very good; but it displays more ingenuity than practicability.

NORTHERN DISTRICT TELEPHONE COMPANY.—This company, who have been doing some good work in the Newcastle district during the past six months, have now completed the chain of trunk wires connecting Darlington with Newcastle and Tyneside. The following towns are now in communication:—Newcastle, Sunderland, Tyne Dock, Jarrow, Gateshead, South Shields, East and West Hartlepool, Stockton, Middlesbrough, and Darlington. A very perfect system has been completed, which will be further improved when Durham and Auckland are added to the list. We may state that the excellent arrangements of the Darlington Exchange have been carried out under the personal supervision of Mr. H. A. Henderson, the local engineer to the company, while the trunk wires have been erected by Mr. G. F. L. Preston and Mr. C. F. Bailey, the engineers respectively at Stockton and Hartlepool.

WATER COLOURS AND THE ELECTRIC LIGHT.—In an article on "Light and Water Colours," contributed to the June number of the *Nineteenth Century* by J. C. Robinson, the following passage occurs: "The action of the electric light on water colour pigments is a question of much interest, and it is greatly to be desired that some competent scientific authority should practically investigate it. The feasibility of the exhibition of water colour drawings in our public collections literally depends upon a favourable solution of this question, for nothing is more certain than that the continuous exhibition of water colour drawings of past epochs by daylight inevitably entails their rapid, irremediable, and more or less complete and final deterioration. It is not unlikely that the white or bluish 'arc' light would, though in a far less degree, be as destructive as the sun's light to mutable pigments; but the yellow 'incandescent' light, on the contrary, would probably be found to exercise no perceptible bleaching influence."

TELEGRAPHIC COMMUNICATION.—"J. E. K." writes to *The Times*:—"If I might generalise from a single district I should say that the state of our telegraphic communications calls for immediate and serious attention. A complaint which I made to the West District office in Vere-street has brought to my knowledge the fact that the number of blunders which draw forth similar complaints to that office alone amounts to 30 or 40 a day. Possibly some of these may be attributable to the senders—mine was not; but to set against this we must take into account those about which the offices hear nothing. Telegraphic communications are for the most part about matters of more than ordinary importance, and such as need more than common expedition; but if addresses containing three figures, say 184, are wired with only one (8), what chance is there of the message reaching its destination within any time upon which the sender can reasonably calculate? This is one specimen of the variety of blunders to which we shall continue to be liable until greater care is exercised, and more efficient agents are employed."

DISASTROUS THUNDERSTORMS.—On Saturday last one man was killed and several persons injured by lightning at Wigan. The thunderstorm broke over the town, and lightning struck a party of spectators surrounding a booth outside the public park. Seven persons were thrown down, and it was found that one was dead and two others partially paralysed. The lightning was very vivid and the thunder was extraordinarily loud. At Golborne the church tower was stripped of its slates, and some narrow

Digitized by Google

escapes are reported. A severe thunderstorm broke over South Dorset in the evening, and was accompanied by a tremendous fall of hailstones. Considerable damage has been done to the growing crops.—A very severe thunderstorm broke over Christchurch about six o'clock in the evening, and during its rage it did damage to the Priory Church; the vane, which was erected in 1659, being struck by the electric fluid, and the massive oak post upon which it was fixed split into pieces. The roof of the old tower, 120ft. high, was also considerably damaged. Many of the pieces of oak were carried into Colonel Tighe's grounds at some distance from the church, but, fortunately, no one was injured.

TAMPERING WITH TELEGRAPH MESSENGERS.—An important prosecution under the Telegraph Act was heard at the Bradford Borough Court on Tuesday. Emmanuel Eastwood was charged with inciting a telegraph messenger to wilfully delay a message. It was stated by the police that his object in delaying messages was to make fraudulent bets. He was in receipt of telegrams respecting races himself, and on several occasions he had met messengers on their way to Morgan's News Rooms in Kirkgate, where the results of races are posted, and endeavoured to delay the delivery of the messages in order that he might have time to take fraudulent advantage of his own information. The specific charge was committed on the 14th inst., when he met a messenger, and offered him 3d. to "play about" with his message. Two other messengers gave evidence as to the prisoner attempting to induce them to delay the delivery of the messages. The case had been reported to the Postal Department, who would probably take it up also. Prisoner, in answer to the charge, denied that he had interfered with the messengers in the manner alleged. He had simply told them to "hurry up" with his own private messages. Prisoner was committed to the Sessions for trial.

INCANDESCENT LAMPS IN MINES.—An interesting application of the electric incandescent light to mining recently took place at Lord Vernon's Poynton and Worth Colliery, near Stockport. It appears that the lower pump rod of the main pumping shaft of the Lady Pit, by which the pits are drained, broke, leaving the bucket in the bottom some 600ft. below, and submerged in water. To remedy the rupture divers were employed from the firm of Siebe, Gorman, and Co, the well known submarine engineers, of Westminster, and their operations were carried on by the light of a Siebe diver's electric lantern, worked by Thame's primary battery. The barrel of the shaft was disjointed and pulled up, and the pump rod was repaired by this means. The Siebe lantern is a strong appliance, and weighs some 83lbs. out of water. It consists of an iron cover permitting the conductors to pass inside to a cluster of four incandescent lamps, the light of which is reflected downwards by a white reflector in the roof. A stout glass globe encircles these, and is protected from injury by iron prongs around it. Fifteen cells of Thame's primary battery were employed, and the total light obtained was about 80 candles, a luminous sphere of some 6ft. in radius being obtained under water.

PROFESSOR BELL'S PATENT.—Another decision in favour of Prof. Bell has just been arrived at in the New Orleans suit, Judges Parder and Billings confirming all the prior decisions obtained in the American courts as to the validity of his patents. The Court has decided that the ground, if not the principal ground, of defence in the action, namely, that the invention of Bell lacked novelty because it had been anticipated by Philip Reis, has not been made out. It admits that Reis made great strides towards "the discovery of the great fact or law" announced in Bell's fifth claim, but added that the fact that he failed to reach it was equally beyond doubt. It was, moreover, in the opinion of the Court overwhelmingly established that Bell made the affidavit to his claim and specifications as originally filed on the 26th of January, 1876, while Gray's description of his invention embodied in his caveat was not written out till three or four days prior to February 4, when it was filed. The judges said, in conclusion, that from the evidence submitted in the case it seemed clear, in the present stage of telephony, that neither the Reis instruments nor any reproduction of them could be made to transmit articulate speech, "except by changes of some form in the instruments themselves or by the employment of Bell's method." The whole interest of the telephone controversy centres now in the case of Prof. Elisha Gray; and the Government, it is said, is meantime collecting evidence abroad to be used in its suit to annul the Bell patent.

GAS WELLS FIRED BY LIGHTNING.—The burning of natural gas wells in Pennsylvania are sights as thrilling to the beholder as they are dangerous to adjacent property. We have given the particulars of these on various occasions. Recently one of these wells took fire, and a volume of flame shot up into the air for several hundred feet with a velocity that was astounding, showing that the pressure of gas from beneath was something beyond comprehension. This well burned for a long time in spite of all efforts to shut off the flame. It was finally done by means of a huge extinguisher, which was advanced slowly to the mouth of the well, and then raised vertically, thus shutting off the air and smothering the flame. A few days since, one of these wells was set on fire in a very curious manner. The workmen had drilled down until gas in small quantities was found to arise through the boring. A sudden storm came up, the atmosphere became thick and prevented the gas from rising freely. The workmen anticipated trouble, and hastily departed from the well. They had scarcely get to a safe distance when a flash of lightning ignited the gas in the atmosphere over the well; flames instantly communicated to the well itself, the result being that the gas in the lower regions was released, and shot upward with a terrific flame to a height of 200ft. or more. The well burned for several days, the column of flaming gas mounting into the air and lighting up the surrounding country for miles. Another well was struck at the same time in another section of the oil regions, and was burning for a long time, threatening adjacent property. Fires occurring in the products of the oil regions, whether gas or oil, are extremely difficult to extinguish, and the amount of property lost in consequence of them is immense.—*Fireman's Journal.*

ELECTRIC STREET CARS IN PHILADELPHIA.—The Union Electric Company has recently been operating an experimental electric motor car on Ridge Ave., between 32nd and 33rd Streets, Philadelphia, and has met with very fair success. Each afternoon a car, carrying the usual burden of passengers, has been run over the track at the rate of nine miles an hour. The system employed is that of underground electrical transmission. A conduit, 4½in. wide by 9in. deep, and having a central slot similar to that employed on cable roads, extends along the centre of the track. This has been laid on concrete, and covered with Portland cement. At suitable intervals, connections are made with the sewer, in order to permit the rain water to discharge or the conduit to be washed out, should that become necessary. A copper conductor, one-quarter inch deep by one inch wide, runs along the conduit on each side of the slot. A grooved piece of channel iron is attached to the bottom of the conductors. A so-called "traveller," supported by wheels,

Digitized by Google

runs in the slot, and is provided with two springs which slide along the channel irons on each side of the slot, and thus receive the electric current. The traveller is connected to the car by small chains. From its centre wires extend into the car, connecting the motor on board with the copper conductors in the conduit, by which the electric circuit may be closed. A regulator on the car controls the current, and permits the car to be driven in either direction. The trials covered a very stormy period, but it is stated that the bad weather caused no interruption in the working of the system. The estimated cost per day of running the electric car, according to the *Ledger*, is $1·84, while that of operating a horse car is $4·74. Neither estimate includes salaries. The cost of ten miles of electric railway on this system, and fifty cars, is stated to be $175,000.

THE ELECTRIC LIGHT IN THE TEMPLE.—On the occasion of the visit of Princess Louise to the Temple Church on Saturday, to celebrate the fiftieth anniversary of the reign of her Royal mother, not the least interesting episode was the illumination of the sacred edifice by the electric light. The installation altogether consisted of sixty-two incandescent lamps attached to fourteen electroliers of hand-wrought iron of simple and chaste design, ten of which contained five burners and four of them three burners. The brass candelabra were all removed, greatly improving the effect, and giving the impression that the edifice was enlarged. The light was also introduced with great success into the Parliamentary Chamber, the reception rooms, and the Hall. In the latter a temporised stage was fitted up, under the superintendence of Mr. Henry Irving, for the representation of the "Midsummer Night's Dream," the principal characters of which were assumed by barristers and benchers of the Temple. A number of incandescent lamps were placed immediately above the stage curtains, and others did duty as footlights, their effect on the tapestry and floral decorations evoking the greatest admiration on the part of the Royal and other visitors. At the back of the stage there was a marble bust of Her Majesty, adorned with a floral wreath of quite a new material in the way of decorative art, resembling biscuit china, but which in reality was plaster of paris ornamentature, reproducing by means of electricity from natural ivy and laurel leaves exact replicas of the real foliage in plaster. Amongst these artificial wreaths some lamps were tastefully distributed, producing a most pleasing effect. In the Parliamentary Chamber there was also a bust of the Princess Louise, placed on a pedestal surrounded by flowers, in the midst of which a few lamps were arranged in such a manner that the effect of their light on the marble figure was the same as if it had been visited by a glimpse of the afternoon sun. Outside the building a very powerful arc lamp was put up, and was fed by the incandescent leads without the usual resistance apparatus employed to prevent the incandescent lamps pulsating, and gave out a brilliant light of remarkable steadiness. Throughout the evening the lamps were run at their nominal candle-power, and were pronounced an emphatic triumph for the electric light. The work was carried out by Messrs. Mortimer and Shepherd, and the effective manner in which it was done redounds to the credit of the firm; in fact, we should not be surprised to find that the system adopted to beautify the scene in this case was extensively followed hereafter.

COLONIAL AND INDIAN EXHIBITION.—At the Conference on Wednesday, June 23rd, a paper was read by Mr. W. Lant Carpenter on "The Position of Science in Colonial Education." The colonies to which Mr. Carpenter had directed his attention were:—Canada generally; in South Africa, the Cape of Good Hope and Natal; Western and South Australia, Victoria, New South Wales, Queensland, New Zealand, and Tasmania, the last of which, unfortunately, was not represented at the present Exhibition. An account of the present condition of scientific education in each of these colonies was given. As a general conclusion, Mr. Carpenter thought that the claims of science to a place in State-aided primary education were more fully recognised than in the old country, and this, not merely because it was the only foundation upon which a system of technological education could be securely built, but for its value in drawing out the minds of the pupils. As regards the branches by which the time-honoured routine of subjects may be most beneficially varied, precedence was almost universally accorded to drawing, and to the objective presentation of the elements of science. In secondary grammar and high schools, however, science scarcely occupied a position equal to that in corresponding English schools, but there were many signs of improvement in this respect. In the colleges and universities of the older colonies, the classical and academic influence was still very strong, while in the newer ones the claims of scientific education to be put on an equal footing with literary were recognised. Great as had been the progress of public opinion in England during the last few years on the importance of science as an element in education, the author was disposed to consider it greater in the colonies in the same period. Certainly the development of that opinion to its present point had been much more rapid in the colonies than at home. There were many voluntary colonial associations for the promotion of science, and the author concluded his paper by throwing out the suggestion that, if there were grave and practical difficulties in the way of an Imperial federation of the Australian colonies, the establishment of an Australian association for the advancement of science, somewhat on the lines of the British and American associations for similar purposes, might not be beyond the reach of practical scientists, and he was strongly of opinion that such a federation would tend to strengthen "the position of science in colonial education."

PRIMARY BATTERIES.—We have again to utter a word of warning against the many attempts which are being made to force upon the confiding public primary batteries for electric lighting purposes. It is only under exceptional circumstances that a primary battery can be used for such a purpose, and it may be at once stated that whenever used it must be looked upon more as a luxury than as a part of ordinary everyday commercial work. We are led to make these remarks from a notice which appears in an Indian contemporary to the following effect: "Numerous attempts have been made to obtain a successful incandescent electric light by means of secondary storage batteries, charged from dynamos; but, owing to the small amount of electricity obtained in comparison with the power required, these batteries have so far, we believe, not been proved to be a commercial success. One of the latest improvements in this direction has been the production of a primary battery, named the 'Aurora,' which is really an improved bichromate solution battery, having a power which is remarkable for its size, and the advantage of not polarising, heating, or evolving any deleterious gases. Each cell holds about a gallon of the exciting fluid, which, we are informed, is made by a peculiar patented process, and is the important factor in the success of the battery. Two large carbon plates are placed outside of the porous cup, and in the latter is inserted the zinc, of a special form to expose a large amount of surface. In the porous cup is put water, which in a few hours becomes charged with the exciting fluid from the outside of the jar. The zincs are

Digitized by Google

well amalgamated to prevent local action." We shall probably have a good deal to say upon this question of primary batteries in the near future, inasmuch as at the present time two primary batteries are being brought to the attention of the English public. One of these, the Lalande battery, has been tried carefully and upon a practical scale. The idea of the owners of this battery is to increase their income by the manufacturing and the sale of what may be termed "bye products." In this, following the example of the gas companies, they take all the trouble of seeing to the batteries, emptying and renewing the liquid, &c., upon their own shoulders, the user having no more trouble than he has in the case of gas. Then Messrs. Woodhouse and Rawson are bringing forward the Upward battery, which is said to be an entirely new departure to give good results—and little trouble to the user. Chlorine gas acting upon zinc is the source of the energy in this battery.

LONDON CHAMBER OF COMMERCE.—A Congress of Chambers of Commerce of the British Empire will be held (by special permission of H.R.H. the Prince of Wales), in the Conference Room of the Colonial and Indian Exhibition, South Kensington, on Tuesday and Wednesday, July 6 and 7, from 10 a.m. to 4 p.m. The following Chambers of Commerce or Commercial Associations have signified their intention of taking part in the Congress:—Barrow-in-Furness, Barnsley, Batley, Birmingham, Bradford, Bristol, Cardiff, Cleckheaton, Derby, Dewsbury, Dudley, Exeter, Falmouth, Gloucester, Halifax, Heckmondwike, Huddersfield, Hull, Kendal, Kidderminster, Leeds, Liverpool, Llanelly, Luton, Macclesfield, Middlesborough, Morley, Newark-on-Trent, North Shields, Newcastle-on-Tyne, Newport (Mon.), Nottingham, Oldham, Ossett, Plymouth, Portsmouth, Sheffield, Southampton, Stockton-on-Tees, Sunderland, Swansea, Wakefield, Walsall, Warrington, Wolverhampton, Worcester, Aberdeen, Dundee, Greenock, Leith, South of Scotland, Belfast and Dublin, Jersey; the Chamber of Manufacturers of Adelaide, and the Chambers of Commerce of Adelaide, Auckland, Christchurch, Dunedin, Suva (Fiji), Hobart, Invercargill, Launceston, Maryborough, Melbourne, Napier, Nelson, Sydney, and Wellington; the Boards of Trade of Toronto, Montreal, Quebec, and Hamilton; the Chamber of Commerce of Hong Kong, the Chambers of Commerce of Bombay, Bengal (Calcutta), Colombo (Ceylon), and Madras; the Chambers of Commerce of Rangoon (British Burmah), and Singapore; the Chambers of Commerce of Cape Town, Durban, Mossal Bay, and Port Elizabeth; the Royal Agricultural and Commercial Society, British Guiana; the Chambers of Commerce of Barbadoes, Jamaica, and Trinidad; British Chamber of Commerce in Paris. Among the questions for discussion is that of postal and telegraphic reform, which will consider the possibility of an Anglo-Colonial Penny Postal Union; extension of the telegraph system; reduction of rates; neutralisation of cables, &c. Opener:—For postal matters, J. F. Hutton, Esq., M.P.; for telegraphic matters, John Pender, Esq. The following resolution will be proposed:—That the reduction of the Anglo-Indian and Colonial postal and telegraph charges, and the neutralisation of cables, be commended to Her Majesty's Government and to the Governments of the various Colonies as desirable in the interests of the Empire and of international commerce; and this Congress strongly urges upon Her Majesty's Government to advance such objects, when possible, by international treaty, and by inviting the joint action of the Colonial and Indian Governments thereon. In this view the Congress particularly points to the desirability of the assimilation of the Colonial and Indian postal tariffs to those of the International Postal Union.

TELEPHONIC STATISTICS.—The following is a continuation from our last issue of M. Rothen's telephonic statistics:—

New Zealand.

Towns.	No. of Subscribers.	Population.	Population per Subscriber.	No. of daily calls per Subscriber.
Dunedin	343	43,846	128	8·1
Auckland	320	34,088	106	5·6
Wellington	204	22,825	112	9·25
Christchurch	184	32,915	179	10·2
Invercargill	41	9,350	228	4·4
Nelson	39	7,287	178	4·0
Oamaru	33	6,587	200	2·5

This information is brought up to the 30th April, 1885. All the exchanges are in the hands of the Government. The subscription varies from 200fr. to 250fr. It is 225fr. for the first 100 subscribers to a new exchange for the first year, and 200fr. for following years. The maximum distances is for houses of business, 800 metres; for private houses, 1,600 metres; for every 400 metres additional distance they pay in the first year 25fr. and for succeeding years 19fr. The subscribers who subscribe after the opening of an exchange pay in the first year 250fr., and in the following years 200fr. A second communication costs 175fr. There are in all the exchanges a total of 22 public rooms. Up to the 31st December, 1884, the total expenses for the construction of the exchanges amounted to 660,895fr. The preliminary maintenance and repairing expenses amounted to 141,170fr., and the receipts to 241,000fr. There are besides the exchanges mentioned 110 telegraphic offices furnished with telephonic appliances.

Inter-Urban Communication.

The second period in telegraphic progress is that introducing and developing the interconnection of towns telephonically. Up to the time these statistics were compiled the following interconnections had been completed. The approximate distance in miles is given within parentheses:—

Austro-Hungary.

Gleichenberg–Gablonz (12½).

Belgium.

Bruxelles–Anvers.
Bruxelles–Gand.
Bruxelles–Louvain.
Bruxelles–Liége.
Bruxelles–Charleroi.

This connection works by the Van Rysselberghe system.

France.

Lille–Roubaix–Tourcoing.
Elbœuf–Louviers.
Paris–Reims (110).
Rouen–le Havre.

Between Paris and Reims and Rouen and Havre the Van Rysselberghe system is in operation.

Great Britain.

London-Brighton.
Accrington-Ashton-Blackburn-Blackpool-Bolton-Burnley-Bury-Derven-Heywood-Liverpool.
Manchester-Salford.
Middleton-Oldham-Preston-Radcliffe-Rochdale-Runcorn-Widnes-St. Helens-Southport-Stalybridge-Stockport-Warrington-Wigan.
Sunderland-South Shields-Newcastle-North Shields.
Dundee and Forfar-Perth-Arbroath.
Tynedock-Yarrow-Newcastle.
Glasgow-Edinburgh-Greenock-Paisley-Coatbridge-Dumbarton-Hamilton.
Bradford-Leeds-Huddersfield-Halifax-Dewsbury-Wakefield-Sheffield.
Birmingham-Wolverhampton-Wednesbury.
Nottingham-Loughborough-Long Eaton-Basford-Ilkeston.
Whitehaven-Workington-Maryport.
Wingate Colliery-Hartlepool (12).
Sunderland-Hartlepool.
Cardiff-Newport.
Keighley-Bradford.
Belfast-Augusta.

United States of America.

Kansas City–St. Louis (320).
Milwaukee–Oskosh (175).
Boston–Portland (116).
Worcester–Springfield (99).
Madison–Milwaukee (87).
Chicago-Elgin (62).
Tremon–Columbus (49).
Boston–Worcester (45).

Besides these communications there are a great many others, as to which we have not been able to obtain accurate information.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XXVIII.

BY OLIVER HEAVISIDE.

(Continued from page 89.)

Some Special Results Relating to the Rise of the Current in a Wire.

Premising that the wire is of radius a_1, conductivity k_1, inductivity μ_1; that the dielectric displacement outside is ignored; and that the sheath for the return current is at distance a_2, and is so thin that variations of current density in it may be ignored, so that merely the total return current need be considered; that a_4 is the small thickness of the sheath, and k_3 its conductivity, we have the determinantal equation (30*b*). Let now

$$L_0 = 2\mu_2 \log(a_2/a_1), \quad R_1 = (k_1 \pi a_1^2)^{-1}, \quad R_2 = (2\pi a_2 a_4 k_3)^{-1}.$$

L_0 is the external inductance per unit length, *i.e.*, the inductance per unit length of *surface* current, ignoring the internal magnetic field. R_1 and R_2 are the resistances per unit length of the wire and sheath respectively, and $\frac{1}{2}\mu_1$ is the internal inductance per unit length, *i.e.*, the inductance per unit length of uniformly distributed wire current when the return current is on its surface, thus cancelling the external magnetic field. We can now write (30*b*) thus:—

$$J_0(n_1a_1) = J_1(n_1a_1)\{\tfrac{1}{2}n_1a_1(L_0/\mu_1) - (\tfrac{1}{2}n_1a_1)^{-1}(R_2/R_1)\}; \quad . \quad (31b)$$

and, in this, we have

$$\left.\begin{aligned} -n_1^2 a_1^2 &= 4\pi\mu_1 k_1 p a_1^2 = 4p\mu_1/R_1, \\ J_0(n_1a_1) &= 1 - \frac{n_1^2a_1^2}{2^2} + \frac{n_1^4a_1^4}{2^2 4^2} - \ldots, \\ J_1(n_1a_1) &= \tfrac{1}{2}n_1a_1\left(1 - \tfrac{1}{2}\frac{n_1^2a_1^2}{2^2} + \tfrac{1}{3}\frac{n_1^4a_1^4}{2^2 4^2} - \ldots\right). \end{aligned}\right\} (32b)$$

From (31*b*) we see that the two important quantities are the ratio of the external to the internal inductance, and the ratio of the external to the internal resistance, *i.e.*, the ratios L_0/μ_1 and R_2/R_1.

Suppose, first, the return has no resistance. Draw the curves $y_1 = J_0(x)/J_1(x)$ and $y_2 = \frac{1}{2}(L_0/\mu_1)x$, the ordinates y, abscissæ x, which stands for n_1a_1. Their intersections show the required values of x. The J_0/J_1 curve is something like the curve of cotangent. If L_0/μ_1 is large, the first intersection occurs with a small value of x, so small that $J_0(x)$ is very little less than unity, so that a uniform distribution of current is nearly represented by the first normal distribution, whose time constant is a little greater than that of the linear theory. The remaining intersections will be nearly given by $J_1(x) = 0$. On the other hand, decreasing L_0/μ_1 increases the value of the first x; in the limit it will be the first root of $J_0(x) = 0$. Thus, if the wire be of copper, and the return distant (compared with radius of wire), the linear theory is approximated to. If of iron, on the other hand, it is not practicable to have the return sufficiently distant, on account of the large value of μ_1, unless the wire be exceedingly fine. Even if of copper, bringing the return closer has the same effect of rendering the first normal system widely different from representing a uniform distribution of current. It is the external magnetic field that gives stability, and reduces differences of current density.

Next, let the return have resistance. The curve y_2 must now be $y_2 = \frac{1}{2}(L_0/\mu_1)x - 2(R_2/R_1x)$. The effect of increasing R_2 from zero is the opposite of that of increasing L_0. It increases the first x, and tends to increase it up to that given by $J_1(x) = 0$, (not counting the zero root of this equation). Thus there is a double effect produced. Whilst on the one hand the rapidity of subsidence is increased by the resistance of the sheath, on the other the wire current in subsiding is made to depart more from the linear theory uniform distribution. The physical explanation is, that as the external field in the case of sheath of no resistance cannot dissipate its energy in the sheath it must go to the wire. But when the sheath has great resistance the external field is killed by it; then the internal field is self-contained, or the wire current subsides as if $J_1(x) = 0$, with a wide departure from uniform distribution. This must be marked when the wire circuit is suddenly interrupted, making the return resistance infinite.

Now, let there be no current at the time $t = 0$, when put on, and keep on, a steady impressed force, of such strength that the final current density in the wire is Γ_0. At time t the current density Γ at distance r from the axis is given by

$$\Gamma = \Gamma_0\left[1 - \Sigma\frac{2}{n_1a_1}\frac{(R_1+R_2)J_0(n_1r_1)/J_1(n_1a_1)R_1}{1 - R_2/\mu_1 p + \{J_0(n_1a_1)/J_1(n_1a_1)\}^2}\epsilon^{pt}\right]$$

where the n_1a_1's are the roots of equation (31*b*). And the total current in the wire, say C_1, and with it the equal and opposite sheath current will rise thus to the final value C_0,

$$C = C_0\left[1 - \Sigma\frac{4}{n_1^2a_1^2}\frac{(R_1+R_2)\epsilon^{pt}/R_1}{1 - R_2/\mu_1 p + \{J_0(n_1a_1)/J_1(n_1a_1)\}^2}\right]$$

It will give remarkably different results according as we take the resistance of the wire very small and that of the sheath great, or conversely, or as we vary the ratio L_0/μ_1. Infinite conductivity shuts out the current from the wire altogether, and so does infinite inductivity; the retardation to the inward transmission of the current being proportional to the product $\mu_1k_1a_1^2$. Similarly, if the sheath has no resistance, the return current is shut out from it. In either of these shutting out cases the current becomes a mere surface current, what it always is in the initial stage, or when we cannot get beyond the initial stage, by reason of rapidly reversing the impressed force, when the current will be oppositely directed in concentric layers, decreasing in strength with great rapidity as we pass inward from the boundary. But if both the sheath and the wire have no resistance, there will be no current at all, except the dielectric current, which is here ignored, and the two surface currents.

The way the current rises in the wire, at its boundary and at its centre, is illustrated in "Induction in Cores." For the characteristic equation of the longitudinal magnetic force in a core placed within a long solenoid, and that of the longitudinal current in our present case, are identical. The boundary equations are also identical. That is, (31*b*) is the boundary equation of the magnetic force in the core, excepting that the constants L_0/μ_1 and R_2/R_1 have entirely different meanings, depending upon the number of turns of wire in the coil, and its dimensions, and resistance. If, then, we adjust the constants to be equal in both cases, it follows that when any varying impressed force acts in the circuit of the wire and sheath, the current in the wire will be made to vary in identically the same manner as the magnetic force in the core, at a corresponding distance from the axis, when a similarly varying impressed force acts in the coil circuit (which, however, must have only resistance in circuit with it, not external self-induction as well). Thus, we can translate our core solutions into round straight wire solutions, and save the trouble of independent investigation, in case a detailed solution has been already arrived at in either case.

Refer to Fig. 3, p. 387, *The Electrician*, September 6, 1884. It represents the curves of subsidence from the steady state. The "arrival" curves are got by perversion and inversion, *i.e.*, turn the figure upside down and look at it from behind. The case we now refer to is when the sheath has negligible resistance, and when we take the constant $L_0 = 2\mu_1$, which requires a near return when the wire is of copper, but a very distant one if it is iron.

Regarding them as arrival curves, the curve h_1h_1 is the linear theory curve, showing how the current density would rise in all parts of the wire if it followed the ordinarily assumed law (so nearly true in common fine wire coils).

The curve H_aH_a shows what it really becomes, at the boundary, and near to it. The current rises much more rapidly there, in the first part of the variable period, and much more slowly in the later part. From this we may conclude that, when very rapid reversals are sent, the amplitude of the boundary current density will be far greater than according to the linear theory; whereas if they be made much slower it may become weaker. This is also verified by the separate calculation in "Induction in Cores" of the reaction on the coil current of the core currents when the impressed force is simple harmonic, the amplitude of the coil current being lowered at a low speed, and greatly increased at high speeds. (*Electrician*, June 14, 1884.)

The curve H_0H_0 shows how the current rises at the axis of the wire. It is very far more slowly than at the boundary.

Digitized by Google

But the important characteristic is the preliminary retardation. For an appreciable interval of time, while the boundary current has reached a considerable fraction of its final strength, the central current is infinitesimal. In fact the theory is similar to that of the submarine cable; when a battery is put on at one end, there is only infinitesimal current at the far end for a certain time, after which comes a rapid rise.

Between the axis and the boundary the curves are intermediate between H_aH_a at the boundary and H_0H_0 at the axis, there being preliminary retardation in all, which is zero at the boundary, a maximum at the axis. It is easy to understand, from the existence of this practically dead period, how infinitesimally small the axial current can be, compared with the boundary current, when very rapid reversals are sent. The formulæ will follow.

The fourth curve h_0l_0 shows the way the current rises at the axis when the return has no resistance, but when at the same time there is no external magnetic field, or $L_0'/\mu_1 = 0$. The return must fit closely over the wire. We may approximate to this by using an iron wire and a close-fitting copper sheath of much lower resistance. There is preliminary retardation, after which the current rises far more rapidly than when L_0/μ_1 is finite.

That is, the effect of changing L_0'/μ_1 from the value 2 to the value 0 is to change the axial arrival curve from H_0H_0 to h_0h_0. Suppose it is a copper wire. Then $L_0 = 2$ means $\log(a_2/a_1) = 1$, or $a_2/a_1 = 2{\cdot}718$. Thus, removing the sheath from contact to a distance equal to 2·7 times the radius of the wire alters the axial arrival curve from h_0l_0 to H_0H_0. Now this great alteration does not signify an increased departure from the linear theory (equal current density over all the wire). It is exactly the reverse. We have increased the magnetic energy by adding the external field, and, therefore, make the current rise more slowly. But the shape of the curve H_0H_0, if the horizontal (time) scale be suitably altered, will approximate more closely to the linear theory curve h_1h_1. By taking the sheath further and further away, continuously increasing the slowness of rise of the current, we (altering the scale) approximate as nearly as we please to the linear theory curve, and gradually wipe out the preliminary axial retardation, and make the current rise nearly uniformly all over the section of the wire, except at the first moment. In fact we have to distinguish between the absolute and the relative. When the sheath is most distant the current rises the most slowly, but also the most regularly. On the other hand, when the sheath is nearest, and the current rises most rapidly, it does so with the greatest possible departure from uniformity of distribution.

If the wire is of iron, say $\mu_1 = 200$, the distance to which the sheath would have to be moved would be impracticably great, so that, except in an iron wire of very low inductivity, or of exceedingly small radius, we cannot get the current to rise according to the linear theory.

The simple harmonic solutions I must leave to another section. We may, however, here notice the water-pipe analogy (*The Electrician*, July 12, 1884). The current starts in the wire in the same manner as water starts into motion in a pipe, when it is acted upon by a longitudinal dragging force applied to its boundary. Let the water be at rest in the first place. Then, by applying tangential force of uniform amount per unit area of the boundary we drag the outermost layer into motion instantly; it, by the internal friction, sets the next layer moving, and so on, up to the centre. The final state will be one of steady motion resisted by surface friction, and kept up by surface force.

The analogy is useful in two ways. First, because any one can form an idea of this communication of motion into the mass of water from its boundary, as it takes place so slowly, and is an everyday fact in one form or another; also, it enables us to readily perceive the manner of propagation of waves of current into wires, when a rapidly varying impressed force acts in the circuit, and the rapid decrease in the amplitude of these waves from the boundary inward.

Next, it is useful in illustrating how radically wrong the analogy really is which compares the electric current in a wire to the current of water in a pipe and impressed E.M.F. to bodily acting impressed force on the water. For we have to apply the force to the boundary of the water, not to the water itself in mass, to make it start into motion so that its velocity can be compared with the electric current density.

The inertia, in the electromagnetic case, is that of the magnetic field, not of the electricity, which, the more it is searched for, the more unsubstantial it becomes. It may perhaps be abolished altogether when we have a really good mechanical theory to work with, of a sufficiently simple nature to be generally understood and appreciated.

In our fundamental equations of motion

$$\text{curl}\,(e - \mathrm{E}) = \mu\dot{\mathrm{H}}\,; \qquad \text{curl}\,\mathrm{H} = 4\pi\Gamma,$$

suppose we have, in the first place, no electric or magnetic energy, so that $\mathrm{E} = 0$, $\mathrm{H} = 0$, everywhere, and then suddenly start an impressed force e. The initial state is

$$\mathrm{E} = 0,\ \mathrm{H} = 0\,; \qquad \text{curl}\,e = \mu\dot{\mathrm{H}}.$$

Thus the first effect of e is to set up, not electric current (for that requires there to be magnetic force), but magnetic current, or the rate of increase of the magnetic induction, and this is done, not by e, but by its rotation, and at the places of its rotation.

Now, imagine e to be uniformly distributed throughout a wire. Its rotation is zero, except on the boundary, where it is numerically e, directed perpendicularly to the axis of the wire. Thus the first effect is magnetic current on the boundary of the wire, and this is propagated inward and outward through the conductor and the dielectric respectively. Magnetic current, of course, leads to magnetic induction and electric current.

Now, in purely electromagnetic investigations relating to wires, in which we ignore dielectric displacement, we may, for purposes of calculation, transfer our impressed forces from wherever they may be in the circuit to any other part of the circuit, or distribute them uniformly, so as to get rid of difference of potential, which is much the best plan. It is well, however, to remember that this is only a dodge, similar in reason and in effect to the dodges employed in the statics and dynamics of supposed rigid bodies, shifting applied forces from their points of application to other points, completely ignoring how forces are really transmitted. The effect of an impressed force in one part of the circuit is assumed to be the same as if it were spread all round the circuit. It would be identically the same were there no dielectric displacement, but only the magnetic field in question. When, however, we enlarge the field of view, and allow the dielectric displacement, it is not permissible to shift the impressed forces in the above manner, for every special arrangement has its own special distribution of electric energy. The transfer of energy is, of course, always from the source, wherever it may be. The first effect of starting a current in a wire is the dielectric disturbance, directed in space by the wire, because it is a sink of energy where it can be dissipated. But the dielectric disturbance travels with such great speed that we may, unless the line is long, regard it as affecting the wire at a given moment equally in every part of its length; and this is substantially what we do when we ignore dielectric displacement in our electromagnetic investigations, distribute the impressed force as we please, and regard a long wire in which a current is being set up from outside as similar to a long core in a magnetising helix, when we ignore any difference in action at different distances along the core.

(To be continued.)

THE STEAM ENGINE INDICATOR.—XVIII.*

BY AMICE.

Of indicator diagrams from engines of the type shown by Fig. 44 we may now take some examples, and, firstly, a set from a semi-fixed compound engine of the type very largely used for driving small electric lighting installations. Figs. 57 and 58 are from such an engine doing about 50 indicated horse-power. The cylinders of the engine are 8·5 and 17·75 respectively, the strokes being alike. The cranks are at right angles, and there is a receiver of large size, in a

* For Art. 17, see *The Electrician* 4th June, 1886.

Digitized by Google

position between the cylinders, and with them immediately below the smoke box, which retards loss of heat. Both cylinders are, moreover, jacketed with steam direct from the boiler.

From the high-pressure diagrams (Fig. 57) it will be seen that the steam from the boiler, at about 125lb. on the square inch, is cut off at from one-fourth to one-fifth of the stroke, the expansion line being somewhat wavy, partly the effect of the oscillation of the indicator spring and parts, and partly due to re-evaporation, which is somewhat considerable, the pressures at any point after cut off being higher than can be accounted for by any other explanation, even when the amount of steam in clearance space is considered. Exhaust takes place at 40lb. per square inch, a pressure which is fairly uniformly maintained in the receiver. This back pressure is very large,

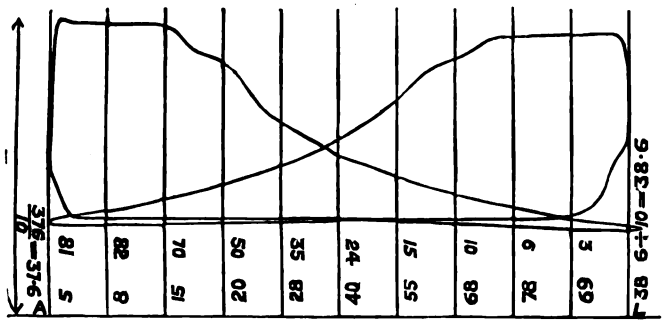

FIG. 57.

but it not only secures a much lower range of temperature in the cylinder than is common in the high-pressure cylinder, and therefore less loss by cooling of the cylinder walls, but the maximum effective pressure on the piston, about 80lb., is low enough to make it unnecessary to use the very tight piston rings which by some makers are used with high pressures. The rings and piston springs are thus more easily kept in order. The loss of pressure between the high and low pressure cylinders is shown by these diagrams to be a little over 3lb. per square inch, which is small. Steam is cut off at about one-third the stroke, expansion taking place in the low-pressure cylinder, and much less than usual in the receiver, which thus acts very much as a boiler for that cylinder. When the diagrams were taken the engine was running at about 125 revolutions per minute, driving 40 arc lamps. The mean pressures in the high-pressure cylinder, as measured and marked on the diagrams, were 37·6lbs. and 38·6lbs., giving 24·8 and 25·4 indicated horse-power in the front and back ends respectively, or a mean of 25·1 horse-power in this cylinder. The mean pressure in the low-pressure cylinder were 14·65lbs. and 15·3lbs., and 27·5 and 29·4 horse-power respectively in the front and back ends, or a mean of 28·4 horse-power. The amount of compression in either cylinder may be considered small considering the speed of the engine, but the results obtained are given by the makers, Messrs. Robey and Co., as highly economical. The mean of a number of experiments with the engine working up to 53 horse-power gave, it is stated, a water consumption of 986lbs. water and 99lbs. of coal per hour. These are exceedingly and almost phenomenally low figures for a non-condensing engine, the water consumption being but 18·6lbs. and the coal consumption only 1·86lbs. per indicated horse-power per hour.

We may now turn to a set of instructive diagrams derived, as explained, with reference to Fig. 44, from a set taken from an engine similar to that just described, and by the same makers, but of 40 nominal horse-power, instead of 20, and fitted with a condenser. Although taken with springs proportionate to the pressures in the cylinders, the two pairs of diagrams D, D′ and L, L′ have been plotted to the same vertical scale. In this form, however, they only serve as separate diagrams, showing the action of the valves, the cut-off, pressures, and the behaviour of the steam. In order to make them more correctly indicative of the performance of the engine and the steam it uses, we have reduced the horizontal scale of the high-pressure diagram by making it proportional to the relation between the areas of the high and low pressure pistons, so that the two diagrams are comparable directly, the scales being the same, and thus enabing us to see at a glance the difference between the diagram that theoretically would be obtainable from the two cylinders if acting as one non-conducting cylinder. The expansion curve C H is the curve A N reduced as described with reference to Fig. 50—that is to say, diagram D is reduced to diagram E, so as to be the same pressure and volume scale as diagram L. The continuation of that curve C H in dotted line H C is an assumed continuation at the same rate of expansion. The space F represents loss of pressure, and its area will represent work lost by reduction of pressure by cooling and frictional influences, and the spaces between low-pressure steam chest and the low-pressure cylinder, *i.e.*, the port and clearance spaces. We have in these diagrams an opportunity of making use of the methods described with reference to Figs. 36 and 38, p. 108, Vol. XVI., of ascertaining the amount of clearance, and of showing graphically the difference between the

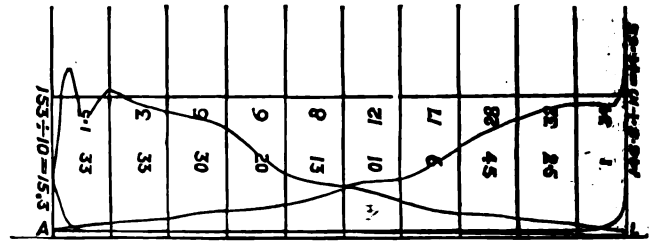

FIG. 58.

theoretical and actual behaviour of the steam in the cylinders. We will take the full diagram D. Supposing the cut-off to have taken place at A on the line C A B, as the diagram D shows, then, if the quantity of steam admitted to the cylinder were only as much as is indicated by the length of the admission line to A, the expansion line by Boyle's law would follow the dotted expansion curve A A′. The actual diagram, however, follows the line A N, which is very much

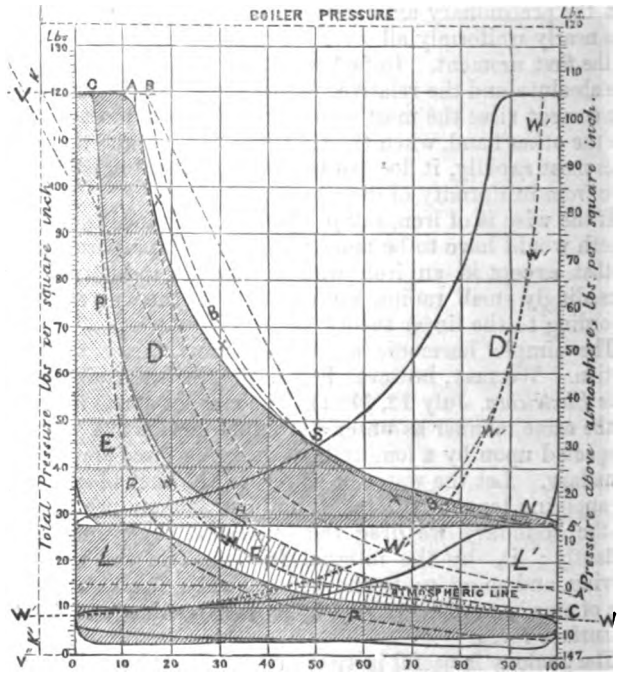

FIG. 59.

above it, showing that a great quantity of steam in excess of that indicated by the length of the admission line, assuming cut-off to have taken place at A. As there is no doubt that cut-off did take place at that point, it is clear that the port and clearance spaces and initial condensation must together be assumed to account for the quantity of steam represented by the area between the curves A N and A A′. Adopting the method described at p. 108, Vol. XVI., we will assume the clearance and port spaces to equal 7 per cent. of

Digitized by Google

the volume of the cylinder, and draw a line K′ K to represent this volume added to that accounted for by the indicator. We may now select a point in the expansion curve whereat the expansion may be assumed to have become regular, as at S. By a vertical from this point to the line of no pressure we get the point 50, and may now get the diagonal 50 K, and parallel with it the line S B, the intersection of the admission line at B giving a length K B of admission line, which corresponds to such an expansion line as A N given by the indicator, but which would give us a true expansion line as shown by the dotted line B B B B′. As the point B is beyond the real point of cut-off A, it is obvious that more than 7 per cent. of clearance, port space, and initial condensation must be allowed for. We may find at once what this is. If we connect S and A by a line, and then draw one parallel to it from 50 we shall get the point V, showing the actual amount of steam admitted to have been 11 per cent. greater than is shown by the indicator diagram D. Knowing now the real volume of steam concerned, we may by the means already explained construct the true or theoretic expansion curve for that volume and the pressures. This we have done, and it is shown by the fine line curve A X X B′. This it will be seen is, as usual, a little higher than the indicator curve in the first part of the expansion, and below it in the latter part of the expansion or of the stroke.

Now, constructing the theoretic curve of expansion or isothermal curve for the diagram D, as reduced to the size of the part marked E, we get the curve marked C P P P, which is the theoretic expansion curve for the whole diagram, consisting of the combined high and low pressure diagrams D and L, the diagram D being reduced in scale to compare with L. This, however, does not take into consideration the 11 per cent. of clearance. Taking this in its proper proportion, remembering that the cylinders are as 3 to 1 in area, we get as the final and true expansion curve for the volume of steam employed, the curve C W W W, which for clearness we have repeated on the unshaded diagrams D′ and L′, as shown by the curve W′ W′ W′. It will be seen that the theoretic curve is coincident with the curve C H from 120lb. down to 60lb. It will be further seen that the real gap between the expansion curve of the lower diagram and the curve W W is lessened by the shaded area comprised between the letters W W H. Practice and theory thus run very close together, and if we were to make a reduction in pressure corresponding to the heat converted into work, the gap shown would really be a very small one indeed.

It should have been mentioned that the dotted line at the heel of the high-pressure curve represents the compression reduced to the scale by which C H is produced.

The engine from which the originals of these diagrams was taken has cylinders 12 and 21 miles in diameter, the stroke is 2ft., the revolutions 90, and the horse-power indicated 90. It is briefly described in the *Proceedings* of the Institution of Mechanical Engineers for August, 1885.

It will be noticed that the highest pressure in the low-pressure diagram is shown the same as the exhaust in the high pressure. This we must assume to be due to the influence of the heated receiver.

A NEW DAMPING APPARATUS.

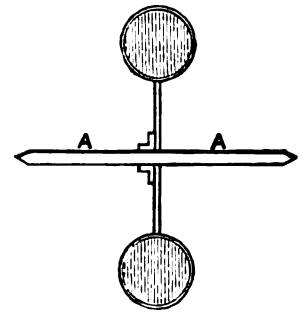
The essential principles of the damping used to still vibrations are of two kinds:—1st, the electric induction of currents in conductors; 2nd, the friction caused by the relative motion of solids and fluids.

To the second class belong vanes moving in air or water.

The scientific investigation of the friction between fluid and solid bodies has often been carried out by means of a hollow ball, set to oscillate when filled with a fluid. The friction of the fluid on the inner wall of the hollow ball itself damps the oscillation.

Dr. Frölich has investigated the question as to what form the hollow vessel should have, so as to make this damping of the vibrations as great as possible, and has found that the best form is a hollow ring rotating round its axis (as shown in section in the figure, where the ring is supposed perpendicular to plane of paper). The ring should be well paraffined inside, filled with water, and closed by soldering.

Such rings can be placed on all instruments for measuring by oscillation, and give a damping whose strength is sufficient for practical purposes, and is unchangeable with time. The



ordinary way of damping by means of a fluid, on the other hand, often requires great care in the management.—*Elektrotechnische Zeitschrift.*

THE ELECTRIC LIGHT AND HIGH TENSION CURRENTS.*

BY E. HOSPITALIER.

The use of high tension currents with underground cables presents still, if we are to credit Mr. Woodbury, of Boston—the inspector of an American insurance company—a certain number of practical difficulties which are yet far from being overcome. Several trials have been made in America without sufficiently satisfactory results having been obtained to lead to the adoption of subterranean conductors.

In a trial made at Boston with a cable 400 metres long, of which the initial insulation was 90 megohms, this insulation gradually fell, and caused important repairs to be so quickly required that it was soon abandoned.

A second line, lead covered, was similarly rendered useless at the end of a few months. The fault of this cable consisted in a disintegration of the insulating substance, quite different in many respects from that produced in overhead wires similarly insulated.

At Philadelphia several explosions of illuminating gas have been attributed to the discharges from an electric lighting circuit.

In Delaware-avenue an underground circuit, which was carefully overhauled and repaired, became in a short time so badly insulated that it was impossible to maintain the light, and an overhead wire had to be fixed in its place. The temperature was so great at the fault that the sand was found to be melted in places, and if these high temperatures were produced inside of dwelling houses in the neighbourhood of combustible materials, very grave consequences would result. A few weeks' experience of an underground circuit is not sufficient for one to find out if this circuit is capable of fulfilling all the conditions of arc lighting from a central station, as faults in conductors only reveal themselves with time.

The difficulties are much less with a low-tension system, such as Edison, where the tension hardly exceeds 100 volts, than in a system of arcs in series, as that of Brush or Thomson-Houston, where the tension may exceed 1,000 volts. In addition to their insulation, which is necessary whether the overhead or underground arrangement is used, subterranean cables should be protected from excessive dryness or excessive moisture, also from natural and accidental variations of temperature, from the action of drains or the escape of gas: they should be capable of resisting the mechanical strains produced in constructing and repairing the roads, and, moreover, they should be cheap.

All these conditions complicate the problem considerably, and, according to Mr. Woodbury, the question is so little advanced, at least in America, that at present underground conductors are considered an element of danger, in proportion to their defective insulation, and the necessity of constructing subterranean channels is against the interests of electricity.

It would be interesting to know the opinion of practical Europeans, and in particular of those who use high tension currents, as Messrs. Gaulard and Gibbs, or Messrs. Zipernowski and Deri. The opinion of Mr. Woodbury appears to us to be rather pessimist, and we shall await further information before pronouncing upon a question so intimately connected with the future of electricity.

ELECTRIC LIGHT FOR CHELSEA.

Among the Metropolitan parishes which have seriously considered the subject of electric lighting, Chelsea has taken a leading part from the very first. The City area was the first to be lighted by electricity, but that circumstance was due to the enterprise of competing companies rather than to any initiative on the part of the City authorities. Chelsea, on the other hand, has investigated the subject in a very thorough-going fashion, has published reports by its surveyor, and has assed an independent judgment favourable, on the whole, to the new illuminant. But whereas the City has allowed the experimenting to be done by outsiders, and is now about to profit by it on its own account, Chelsea appears to have taken a vast deal of trouble only to prepare the way for somebody else. Nobody — except, perhaps, the parishioners — can complain of this, certainly not the CHELSEA ELECTRICITY SUPPLY COMPANY (Limited), who, having obtained a Provisional Order for lighting a portion of Chelsea, are so encouraged by the favourable reception of their scheme as to have pressed it on for confirmation in the House of Commons. The Bill is before us, and it may be useful to glance at it with a view to seeing how the Board of Trade are prepared to treat future negotiators applying for similar powers.

It strikes us as singular that, under existing circumstances, any electric lighting company has had the temerity to seek such powers under the Act of 1882, when that Act was on the point of being thoroughly recast in a shape, to say the least of it, twice as favourable to the undertakers as was the original Act under which the Chelsea Company obtained its Order. The Bill for amending Mr. CHAMBERLAIN'S Act has fallen through in consequence of the premature dissolution of Parliament; but it would appear that the Provisional Order for Chelsea was proceeded with on the basis of the unreformed Act. "This order," says the Bill, "is to be read and construed subject in all respects to the provisions of the Electric Lighting Act, 1882, or of any other Acts or parts of Acts incorporated therewith," by which we do not understand that subsequent legislation altering the conditions upon which provisional orders are to be granted will disturb the conditions under which provisional orders have already been confirmed. We take it that twenty years' grace, with compulsory purchase to follow, are the terms on which the CHELSEA ELECTRICITY SUPPLY COMPANY means to start business, if it does start, and that any better terms hereafter embodied in the original Act will be prospective merely, and not benevolently applicable to people who accepted the earlier and less liberal conditions. We may be mistaken in this view; but that would be a small matter. It would be a very serious matter, however, if the company were to make any mistake about it. We can only suppose that they have preferred to take all the risks and assume all the burdens rather than wait any longer.

Harsh as are the terms of the original Act, the Board of Trade have, it seems to us, made them worse under the confirming order, which bristles with obligations and restrictions, chiefly operative against the undertakers. For example, authority is granted over a certain area, with a nominal power to extend it to a wider prescribed area; but whereas the local authorities can virtually compel the undertakers to extend their operations, the undertakers can be prevented doing so on their own motion if the local authorities or the Board of Trade raise any objection. Again, the capital of the company is a prescribed sum—a very large one, we think, for a beginning—and it is to be virtually held by the Board of Trade and doled out as the work of the undertakers proceeds. And before beginning extensions in the wider area the Board of Trade has power to demand the deposit of such sums as they may think fit—and three-parts of the whole sum required within twelve months. It will be a fortunate concurrence of circumstances that enables any company to earn interest on its capital within a reasonable time under such conditions as these. The undertakers will also be working under the continued supervising and restrictive powers conferred on the METROPOLITAN BOARD OF WORKS and the POST-MASTER-GENERAL, whose rights in every respect are held sacred in this Bill. As regards the conditions under which the company is required to supply electricity, they may be inferred from the following example: "The undertakers upon receiving reasonable notice from the local authority requiring them to supply electricity to any public lamps within the distance of fifty yards from any distributing main . . . . shall give and continue to give a supply of electricity to such lamps in such quantities as the local authorities may from time to time require to be supplied." Thus the undertakers can be compelled to light "lamps"—two would answer the description—but cannot demand to be allowed to light three!

This last is, of course, the great obstacle to electricity competing with gas as a street illuminant. We have no desire to see any injustice done to gas by its premature displacement in favour of the electric light; but, on the other hand, it is rather hard on the vendors of electricity to arbitrarily compel its supply where no profit can be earned. In

Digitized by Google

the particular area, however, to which this Bill relates there are good reasons for expecting a profitable return from private house lighting. Schedule A, the area first to be worked, comprises Sloane-street, with the region behind it, which is undergoing a complete and rapid transformation at the hands of the "Queen Anne" builders, and promoters of aristocratic "Flats." In a very short time every small dwelling house will have disappeared, and its site be occupied by a mansion which makes up in height what it lacks in breadth. The tastes likely to prevail in this sumptuous new colony will favour electric light, which has here a chance of starting without any rival more formidable than inodorous oil, which is exceedingly troublesome, whether it smells or not. No better locality could have been selected for making a start at indoor lighting on a tolerably large scale, and it is this fact probably that induced the CHELSEA ELECTRICITY SUPPLY COMPANY to begin operations, notwithstanding the 27th clause of the original Act and the onerous conditions imposed by the confirming order of the Board of Trade.

CORRESPONDENCE.

A NEW TYPE OF DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue, when describing the new Goolden and Trotter dynamo you say:—"A very similar pattern has recently been produced by Mr. Kapp." Your expression "recently" is, however, somewhat misleading, because with the rapid progress going on all around us one is hardly justified in describing a thing as recent which is more than a few weeks old. Now, by referring to my books I find that the date of design and working drawings for the first single horse-shoe machine falls into the period from the 24th to the 27th July of last year, and that this machine was finished and tested on the 28th of August last year. Moreover, the type of field which you call a recent production, was described and illustrated last November in a paper I read at the Institution of Civil Engineers, and at that time several large dynamos of this pattern had already been made by Messrs. W. H. Allen and Co. to the order of the Admiralty.—Yours, &c.,

Wimbledon, June 21, 1886. GISBERT KAPP.

NERVOUS FORCE AND ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have for the last two or three weeks been engaged on a series of experiments, the results of which are to me striking.

I noticed, in the first instance, that by simply holding in my dry hands the ends of two copper wires covered with gutta percha, and connected with the terminals of a Thomson mirror galvanometer, the needle of the galvanometer was deflected.

Let A and B represent the two terminals. When I speak of the needle deflected to the *right*, it signifies that the current enters the galvanometer through A, and to the *left* through B.

In order to get good contact I used salt water. Now, when I held A (*i.e.*, the wire attached to A) in my left hand, and B in my right hand, the spot of light went rapidly off the scale to the *left*; on the contrary, when A was in my right hand it went off to the *right*. I repeated this on another man, and confirmed the result. But, happening to come across a left-handed human being, I found to my delight that the reverse took place. Thus, when I placed A on his left thumb, the needle turned to the *right*; when on his right thumb, the deflection was to the *left*. I also proved that when one of the wires was in my mouth and the other in either of my hands the current always left my body at the hand; but when I pressed one of the wires against the centre of my forehead and held the other in a hand the current left at my forehead.

The left hemisphere of the brain controls the right side of the body, and the right hemisphere manages the left side.

So, as might be expected, when I held A against the left "bump" of my forehead and B on the right, the needle was deflected to the *right*, and to the *left* when A was on the right "bump."

In addition to these experiments there are several anatomical facts to support the view of the identity of nerve force and electricity. For instance, all the nerve fibres, at least in the cerebro-spinal system, are insulated from one another by what is known as "the white substance of Schwann.' And just as nerve force causes a muscle to contract, so does electricity when the centre of that nerve force has been taken away or destroyed. Witness Galvani's experiments, also an experiment by Dr. Ure, and quoted by Dionysius Lardner, in which the body of a recently executed convict was included in the circuit of a powerful battery:—"When the circuit was closed, the muscles moved with a fearful activity, so that rage, anguish, and despair, with horrid smiles, were successively expressed by the countenance." Finally, there are one or two analogies existing between the brain and a galvanic battery. The following have occurred to me:—

1. In the case of an electric battery, when the circuit is open the current will not flow; but still there is the difference of potential. Similarly, when a person is said to be "paralytic from disease affecting the motor tract," he yet retains the will to act, although not the ability. Thus the *will* corresponds to electromotive force.

2. An electric battery requires to be refilled after a certain amount of use. Exactly so with the brain. And during sleep, which is necessary for the restoring of the brain, the minute cells of the cortex generate a mysterious force with the aid of the blood, which I hope these experiments may tend in some measure to throw light upon.

There are many deductions to be made from these experiments, which, however, I must leave for the present. I am convinced that anything, however small, relating to that by which we live and move and have our being must be of consuming, as it is of vital, interest to all.—Yours, &c.,

ARTHUR WILLEY.

45, Gladstone-avenue, Noel Park, N.,
June 21st, 1886.

P.S.—There is just one deduction which I pick out from the rest, and should like to mention. The experiments seem to show that with right-handed people more nervous force is sent into the right than into the left arm, and the contrary with left-handed people. Thus it seems to me probable that the awkwardness which the former exhibit with respect to the left side and the latter with respect to the right side may in part be explained. Also those muscles which are called upon to do the most work get more nervous force than others which do less work. For example, the hands get more than the mouth.

MILITARY TELEGRAPHY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Baron von Fischer-Treuenfeld's letter in your last issue, may I be permitted to state that I was aware before writing my paper that enough had transpired in various ways about my vibration system to render a full description of it free from any risk of injury to the public service, while in other respects not altogether void of interest, otherwise the paper would not have been written?

As regards the German preference for the Inker, I concur with the writer of your very able leader in thinking it better to leave them to manage their own business, which they have certainly shown that they thoroughly understand. It may not, however, be amiss to point out that 10 miles of telegraph wire may be doing more important work than 1,000.—Yours, &c.,

P. CARDEW.

Chatham, 22nd June, 1886.

LITERATURE.

Electric Transmission of Energy. By GISBERT KAPP, C.E. [London : Whittaker and Co., 1886.]

At a time when there is some hope that the consideration which this subject deserves is about to be accorded to it, the appearance of Mr. Gisbert Kapp's "Electric Transmission of Energy" is singularly opportune. Several years ago a work on the "Electric Transmission of Power" was written by Dr. Paget Higgs, but then the subject was only in its babyhood, and the data at the author's disposal was limited in quantity and of rather inferior quality. Since that work appeared, however, much has been done. The theory of dynamo machines and electro motors, as compared with the state in which it was then, may be said to be complete. The greater part of the mathematical work appertaining to the problem of electro-dynamic transmission is accomplished, and while a great deal has been written on the subject there exist not a few practical examples of its application. Although progress has not been so rapid as was expected in some quarters, and enthusiasts have suffered disappointment in this case as in most other cases, still the transmission of energy by means of electricity may be described as having attained a somewhat promising infancy if it cannot yet be said to have reached a vigorous manhood.

After reviewing in a few introductory pages what has been already accomplished, Mr. Kapp leads off with a chapter on general principles, in which is discussed the co-relation of physical forces, with special reference to the relation between mechanical and electrical energy. A portion of this chapter is devoted to an exposition of Prof. Hughes' theory of magnetism, and the derivation of electro-magnetic units. The happy conception of an ideal transmission system, consisting of two pairs of bars with a slider to each, forming one pair the generator and one the receiver, and connected by a pair of conductors, is introduced in this part of the work, and will be exceedingly helpful to the reader. In this ideal system there is no mechanical friction to deal with, and we have an analytical investigation of the condition for maximum work, whence is derived the well-known result that the counter E.M.F. of the motor must be equal to half that of the supply, or maximum work will be obtained when the motor is loaded, so that the current which flows is equal to half that which flows when it is at rest.

At page 40 the author refers to the starting-power, and points out that in separately excited motors the torque produced is proportional to the current flowing through the armature. Here it is assumed that no distortion, displacement, or weakening of the field is produced by the armature current, but with motors as usually constructed this would not be the case. The torque being proportional to the product of the strength of field and armature current, it is found that, owing to the weakening of the field, it does not increase in separately-excited motors quite so rapidly as the current, while in series motors, on the other hand, it increases more rapidly, the strength of the field up to a certain point being increased as the current is increased. This fact, as is pointed out, is of great importance in the application of motors to tramway or railway carriages.

Mr. Kapp very properly takes objection to the method of determining the efficiency of a system of transmission by comparing the relative speeds of the receiver and generator, since any leak on the line wire would cause the receiver to run at a higher velocity and thus show a higher efficiency under circumstances in which in reality a lower efficiency only is possible. But it is not so easy to see the force of the author's second objection, which he raises because "the two magnetic fields, although produced by the same magnetising power, are not of absolutely equal intensity, because the magnetisation of the armature produced by the current circulating through its coils has a certain influence in altering the intensity of the magnetic field, and this alteration is different in a motor to what it is in a dynamo." If in two identical machines the brushes in the motor have a displacement in a backward direction equal to that which in the dynamo is given to them in a forward direction, we ask why should the influence of the armature on the magnets be different in each case? The currents flowing in the armature and magnets of each are similar; the armature and magnet poles have therefore the same effect, and are in the same position relatively to each other. The resultant magnetic field has the same shape, and, in the absence of anything corresponding to magnetic lag, a notion which appears to be exploded, we do not see how the mere rotation of the armature in a different direction—for this is the only point of difference between the machines—can influence the E.M.F. produced. We do not know the precise conditions under which the curves from the Bürgin machines exhibited at page 126 were obtained, but unless the magnetically irregular form of the armature in some way influenced the field due to its rotation, we should have expected the counter E.M.F. line to coincide with the dynamic E.M.F. line if the brushes were displaced in the former as far backward as in the latter forward, and we should be surprised if in smooth armatures this were not the case. In short, with similar resultant field and similar currents we ought to have produced the same E.M.F.

In Chapter II. the author proceeds from the abstract to the concrete, and describes the results obtained with actual armatures running in actual fields, the expression for the electromotive force produced by an armature of given dimensions being given at page 81. A considerable portion of the chapter deals with the effect of self-induction on motors with shuttle-wound armatures where the counter E.M.F. necessarily alternates twice in each revolution from zero to maximum. Several experiments, details of which are given, lead to the conclusion that in the case of series motors with shuttle-wound armatures of the Griscom type the effect of self-induction by retardation of the magnetism is to steady the current, and thus prevent waste of energy at the dead points where the counter E.M.F. is *nil*. With shunt motors, on the other hand, the self-induction has no effect, and there is a consequent rush of current when the armature is at the dead points, the flow of current which was simply undulatory in the former case being in the latter case subjected to violent changes.

Further on it is observed that the current is independent of the speed, but depends simply on the loads, and that the ratio of E.M.F. to speed is constant; in other words, with a given current the E.M.F. is proportional to the speed as is the case in generators. In discussing the loss of energy due to discontinuity of the armature core, the formation of eddy currents in the poles caused by the sweeping of the Pacinotti teeth over their surfaces is referred to, and the fact that these can be prevented by sufficient clearance between the teeth and the surface is also stated; but Mr. Kapp doubts whether there is any advantage in employing the Pacinotti instead of the usual Gramme type of armature. If there is one requirement more than another on which throughout the book emphasis is laid, it is that the wires carrying the current shall be driven positively by some rigid fastening to the armature, and in his own dynamo Mr. Kapp ensures this by providing radial driving-horns protruding from the gun-metal flanges, between which the iron wire of his core is wound. By some this positive method of driving is not considered essential, but there can be no doubt that if the Pacinotti armature, because of the positive way in which the wire is driven, should ever be employed at all, it is in motors where the torque in starting them is often five or six times that at which they are usually worked.

In Chapter IV. are discussed the different types of field magnets employed in modern dynamos, and formulæ from which we can obtain the strength of field in terms of the ampere-turns are given. These formulæ are only true for very low degrees of magnetisation, since the magnetic resistance of the iron in the armature and magnets increases with the degree to which it is saturated. From numerous experiments Mr. Kapp finds that the magnetic resistance of air is about 700 times that of soft wrought iron well annealed. This is when the field is very weak, but in practice, when the magnets are fairly saturated, the resistance of the iron frequently rises to ten times its original value, in which case the magnetic resistance of air is only 70 times that of iron. Further on, at page 111, Mr. Kapp, in consequence of difficulties experienced

Digitized by Google

when the saturation effect comes into play, abandons the formulæ referred to in favour of representation by graphic methods.

In chapters V. and VI. the author gives his attention to various systems of transmission, and includes in his considerations systems in which the motors are fed by mains at a constant difference of potential, or by a constant current, and systems in which only a single motor is fed at a distance from a single generator. In these cases it is supposed that the motor has to run at a constant speed, and it is also supposed that the speed of the generator shall remain uniform. If in a motor in which the resistance of the armature is very low the magnets are excited by a current which is constant, it may be very nearly self-regulating, the E.M.F. expended in overcoming the resistance of the armature being negligible. In a shunt-motor we can, therefore, by making this resistance sufficiently low, get a machine in which, when fed by a constant E.M.F., the speed does not vary enough to form in practice any objection to its use. Such a motor would do very well to be used in a system where the mains were kept at a constant difference of potential, but another method, namely, that of compound winding, devised some time ago by Profs. Ayrton and Perry, to achieve constant speed with constant potential, may be briefly noticed. When the load on a shunt motor is increased, an additional E.M.F. is expended in the armature, and less is therefore available for external work. The speed with a constant field depends on the difference between the E.M.F. at the motor terminals and that expended in the armature, and it is at once diminished with an increased load. If the speed is to have its original value with a diminished counter E.M.F. it is evident that the field must be weakened, and this Ayrton and Perry accomplish by winding a demagnetising coil on the magnets in series with the armature, so that the increased current weakens the magnets. It must not be supposed for a moment that a compound dynamo will work satisfactorily as a compound motor. It is true the same *kind* of winding is required, inasmuch as they both have a shunt and series coil, but the *proportions* must be very different, and the shunt coil in a compound motor must saturate the magnets to the degree to which they are in a compound dynamo saturated by the shunt and series coils combined. Compound motors we have seen at work; but we have not been particularly struck by their performance. They are an awkward piece of designing. Different to compound dynamos they have, when the current through the armature is a maximum, the weakest field, and are, therefore, extremely liable to sparking unless the turns on the armature are very few. But few turns on the armature means low resistance, and this, as we have said before, may mean a diminution of speed which is inconsiderable. *En passant*, by reason of the current in the armature reacting to weaken the field, does not a shunt motor contain within itself the germ of self-regulation, which by suitable proportion may be made effective without a series coil at all?

To work on a constant current system Mr. Kapp proposes the combination of a motor with a dynamo running at its critical speed. The armature of the latter is fixed on the motor spindle, and tends to demagnetise the field coils of the former. We do not believe that any method of governing which depends upon the action of a dynamo running at its critical speed can be successful; but we wait expectantly for the results obtained from the combination, trusting that the collector will not be ruined by sparking before a sufficient number of readings can be taken.

Passing from our consideration of motors working independently of each other on a constant potential or constant current system, we come to the case of a single motor worked by a single generator. The shunt motor may be employed as a receiver, in which case we have to supply at the motor terminals a constant potential, or potential which may rise somewhat according to circumstances. In consequence of the line having a certain resistance, the E.M.F. at the generator must rise probably 20 per cent., in order that the necessary potential be supplied to the motor, and it is pointed out that an over-compounded dynamo satisfies the requirements for the generator. Of course approximation only is meant here, as it would not be possible to obtain a rise of, say, 20 per cent. in E.M.F. in anything like a straight line without an excessive quantity of iron. Adjustment is possible whereby similar speeds can be obtained from the motor working idly and with full load, but between those two limits there must necessarily be a certain increase. Mr. Kapp instances a curious practical objection to this system of over-compounded dynamo and shunt motor which we have not time to consider, but of which a description was published in *The Electrician* of April 18th, 1885. The difficulties which were encountered in working the system may be avoided by keeping the magnet circuit of the motor always closed, the switch to stop and start the motor being placed in the armature circuit only.

The other transmission system to which reference is made consists of a series-wound motor worked by a series-wound generator, a system which is undoubtedly most advantageous, being self-regulating, if the difference between the ordinate heights of the characteristics of the generator and motor is for all currents equal to the E.M.F. spent in overcoming the resistance of the circuit.

We do not quite see how Mr. Kapp finds γ, the current required to overcome internal friction (page 130). The value of γ, when the motor is running empty, is different to its value when the motor is fully loaded, and if four amperes overcomes the internal friction when running idle, we should imagine something considerably over this would be required when there is a total current of 45 amperes flowing. But although the quantity γ may be somewhat higher than the determination given, still the main fact which the author desires to point out should be carefully noted, and that is, that whereas in a motor having no mechanical friction the efficiency is a maximum when the counter E.M.F. approaches that of the generator, this is not the case when the work expended in internal friction is taken into account.

In Chapter VII. Mr. Kapp considers the question of conductors, and interprets in its proper sense the law of Thomson. It must be remembered that the cost of conductors cannot be expressed simply as proportional to the weight of copper plus a constant for laying, and it is likely that some graphic method of connecting the cost with the line resistance will have to be adopted for each district in order that a correct solution for minimum cost may be arrived at. Again, as has been lately shown by Ayrton and Perry, the truth of the law for minimum cost depends entirely on the way in which the problem is conditioned. If the current is fixed and the resistance only is variable, Thomson's law is applicable; but if the potential at the generator is fixed and the power to be delivered at a distance from it is also fixed, both the current and resistance are variables, and maximum economy is obtained not by keeping the current density constant, but by making it diminish as the length of the line becomes greater. In all cases where the maximum potential at the generator is given, a current smaller than that given by Thomson's formula must be used to obtain maximum economy.

Chapter VIII. deals with the various materials employed for conductors, &c., and in Chapter IX. are given some interesting results relative to the efficiency of power transmission by wire rope, hydraulic, pneumatic, and electric methods. These results are based on the investigations of Herr Beringer, and show that for distances of less than three miles transmission by wire rope is more economical than by any other system. For distances greater than this electric transmission is the most economical. As regards capital outlay, up to about two miles the wire rope is cheapest; beyond this, electric transmission is least costly. Summarising the results obtained by combining the capital outlay and efficiency, Mr. Kapp arrives at the following conclusions:—

1. It pays to transmit cheap water-power; by wire rope if the distance is less than a mile, and electrically if the distance is a mile or more. This applies to all powers.

2. It pays to transmit cheap steam-power if the amount of energy required at the receiving station does not exceed 10 horse-power. If the distance is less than a mile use wire-rope transmission; for distances of one mile and upwards, up to two or three miles, use electric transmission. Beyond this limit a small local steam or gas engine is preferable.

Digitized by Google

According to this three miles is the limiting distance for economical electric transmission if steam power is transmitted. Obviously, our hopes of electric transmission must for the future be centred in water power.

Chapter X. deals with the different forms of modern dynamo, and Chapter XI. describes the various systems of transmission now at work. We recommend readers to study these chapters carefully; for the present we have only space to call attention to an estimate at the end of Chapter XI., where the original outlay for electric traction on tram lines is shown to be only slightly in excess of that required for horse traction, while the annual working expenses for horses is more than double that for electricity.

Chapter XII., describing the successes and failures of M. Marcel Deprez, concludes a valuable work, which we hope to see run through several editions. It is possible that a somewhat better arrangement of the subject matter might be adopted, but doubtless many difficulties of classification have been experienced. Mr. Kapp is not an enthusiast, and the book is written with regard to facts and to facts only. Every circumstance for and against the electric transmission of energy is carefully weighed, and the author, if he gives us no hint as to the future, prohibits by his treatment any charge being brought against him of over sanguineness. What the future may bring we do not know, it is sufficient that we grapple with problems as they are presented to us.

ON THE LIFTING POWER OF ELECTRO-MAGNETS AND THE MAGNETISATION OF IRON.*

BY SHELFORD BIDWELL, M.A., LL.B.

The author believes that no very recent investigations have been made with reference to the maximum lifting power which an electro-magnet is capable of exerting, the experiments conducted by Joule between the years 1839 and 1852 still forming the basis of most of our practical knowledge on the subject.

It is a matter of common experience that if an electro-magnet be excited by a gradually increasing current a limit is soon reached, beyond which the ratio of increase of sustaining power to increase of current becomes rapidly smaller; and it has generally been assumed that this ratio continues to diminish indefinitely, so that an infinite current would not impart to a magnet much greater lifting power than that which it possesses when an approach to saturation is first indicated.

Joule, after having shown by experiment that the power of an electro-magnet varies as its sectional area, expressed the opinion that "no force of current could give an attraction equal to 200lb. per square inch," and much later Rowland stated, as a probable result of his well-known researches in magnetic permeability, that the greatest weight which could be sustained by an electro-magnet with an infinite current was, for good but not pure iron, 177lb. per square inch, or 12,420 grams per square centimetre of section.

It has long been known that when an iron rod is magnetised its length is in general slightly increased. Some experiments on this effect of magnetisation, an account of which has been given in two papers recently communicated to the Royal Society, show that if the magnetisation is carried beyond the point at which the magnetic elongation of the rod reaches a maximum, the length of the rod, instead of remaining unchanged, steadily diminishes, the curve expressing the relation between the length and the magnetising force descending in a perfectly straight line, which within the limit of the experiments shows no tendency to become horizontal. Some further experiments (not yet published) have also been made with rings of iron instead of rods, and effects of precisely the same character were obtained. The diameter of a ring was found to be increased by a comparatively small magnetising current, and diminished by a strong one. Now, the retraction in question does not begin to occur until after the stage of magnetisation, loosely called the "saturation point," has been passed, when, according to the common belief, the magnetisation of the iron has practically reached a limit, and is not sensibly affected by any further increase of the magnetic force; and hence arises a difficulty in accounting for the phenomenon. The most obvious method of explaining the retraction is to assume that, under the influence of increasing currents, the magnetic attraction of the particles of the iron towards one another is increased, and thus the rod becomes compressed. But this cannot be the case if the magnetic condition of the iron has become constant and independent of the magnetising current. And a similar objection will apply to any hypothesis which assumes (as perhaps all must) that some property of the iron dependent upon its magnetic condition varies in a sensible degree with the magnetising force after the "saturation point" has been passed.

The author was led by considerations of this nature to the belief that it would be desirable to make some experiments with the view of ascertaining whether the lifting power and general magnetic condition of an iron rod are as nearly uniform under strong magnetising forces as is commonly supposed. Two pieces of apparatus were therefore prepared. The first consisted of a rod of iron hooked at each end and divided transversely in the middle, together with a long solenoid, inside which the divided rod could be placed. The second was an iron ring cut into two equal parts, each of which was encircled with a coil of insulated copper wire. In both cases the construction was such that an intense magnetic force could be produced with comparatively small battery power. The divided ring could be used either as a semi-circular electro-magnet with a semi-circular armature, or, if the current were passed through both coils, as two semi-circular electro-magnets.

Merely to test the hypothesis of Joule and Rowland, two or three determinations were made of the weight which could be sustained when the current was caused to circulate around one only of the semi-circles, the other being used as an armature. With a current of 4·3 amperes the weight supported was 13,100 grams per square centimetre of surface; with a current of 6·2 amperes the weight supported was 14,200 grams per square centimetre. In the latter case, therefore, the lifting power exceeded that which both Joule and Rowland considered the greatest that could be imparted to a magnet by an infinite current. Had it been worth while to incur the risk of injury to the insulation of the coil, there is no doubt whatever that by applying stronger currents the lifting power might have been carried still further, for there was no indication that a limit was being approached. But it was of greater interest to study the effects produced when both portions of the ring or of the rod were under the direct influence of the magnetising coil.

The first experiment was made with the divided rod. One portion was supported by means of its hook in a vertical position; a scale pan was attached to the hooked end of the other portion, and the flat ends of the two were brought into contact and surrounded by the solenoid. Currents of gradually increasing strength were then caused to pass through the solenoid, and note was taken of the greatest weight which could in each case be placed in the scale-pan without tearing asunder the ends of the two rods. The general results are briefly as follow:—When the intensity of the field at the junction had reached about 50 C.G.S. units, the weight supported was nearly 7,000 grams per square centimetre of the section of the rod. After this value was exceeded it became quite evident that the weight which could be sustained was increasing more slowly than the magnetising current, and the proportionate increase became rapidly smaller as the current was made stronger. This state of things continued until the intensity of the field was about 270 units, when the weight supported amounted to 10,800 grams per square centimetre of section. But from this point onwards *the magnetising current and the weight that could be carried increased in exactly the same proportion.* The rate of increase of the load was, indeed, comparatively small, but it was perfectly constant, and continued so until the field had attained the high intensity of

* Abstract of paper read before the Royal Society, May 20, 1886.

Digitized by Google

1,074 C.G.S. units. Here the experiment was stopped, the greatest weight supported having been 15,100 grams per square centimetre.

On account of some uncertainty as to the possible influence of the external ends of the divided rod, it was thought desirable to make the experiment with the divided ring, the current being caused to pass in the same direction through the coils surrounding both portions. The general character of the results was the same as before, but the weight supported per unit of area was from first to last somewhat greater. The falling off in the rate of increase of the lifting power was well marked when the intensity of the magnetic force had reached 50 C.G.S. units, at which point the weight sustained was about 10,000 grams per square centimetre, and it continued to diminish until the magnetic force was 250 units and the weight supported 14,000 grams. From this point the increments of lifting power and of magnetic force appeared to be exactly proportional, and continued to be so until the magnetic force had been carried up to 585 units, when the limit of the battery power was reached and the experiment stopped, the maximum weight supported having been 15,905 grams per square centimetre or 229·3lb. per square inch.

Detailed results of the experiment with the divided ring are given in the first and second columns of the table. A curve plotted with the magnetic forces as abscissæ and the weights lifted as ordinates becomes sensibly a straight line, inclined to the horizontal axis for values of the magnetic force greater than 240 units.

It occurred to the author that these results might be applied to the investigation of the changes of magnetisation which correspond to changes of magnetic force. The common belief that at a comparatively early stage the intensity of magnetisation becomes sensibly constant is, he thinks, founded rather upon inference than upon actual observation. At all events, he is acquainted with no experiments bearing upon the subject which have been made with magnetic forces at all comparable in magnitude with those used by himself.

If W = the grams weight supported per square cm. of section, $\mathfrak{H}$ = the magnetic force, and $\mathfrak{T}$ = the magnetisation, we have

$$Wg = 2\pi\mathfrak{T}^2 + \mathfrak{H}\mathfrak{T},$$

and by giving to W the values found by experiment to correspond with different values of $\mathfrak{H}$, we have the means of finding corresponding values of $\mathfrak{H}$ and $\mathfrak{T}$. These are given in the first and third columns of the table. Here, again, it will be seen that when $\mathfrak{H}$ has exceeded the value of about 200, the ratio of $\mathfrak{T}$ to $\mathfrak{H}$ no longer continues to diminish, and the curve expressing the relation between them apparently becomes a straight line.

It is not suggested that the portions of both the curves for W and $\mathfrak{H}$ and for $\mathfrak{T}$ and $\mathfrak{H}$, which so far as the experiment goes, differ insensibly from straight lines, would in fact continue to appear as absolutely straight if they were prolonged indefinitely. It is, indeed, probable, that at least one of them tends to a limit; but the experimental results give no indication of the existence of any such limit, and if there is one it must be considerably higher than it is generally believed to be.

If κ denote the susceptibility, μ the permeability, and $\mathfrak{B}$ the magnetic induction,

$$\mathfrak{T} = k\mathfrak{H},$$

$$\mu = 1 + 4\pi\kappa,$$

and

$$\mathfrak{B} = \mu\mathfrak{H}.$$

We can, therefore, easily find the values of K, μ, and $\mathfrak{B}$, which correspond to different values of $\mathfrak{H}$. These are given in the fourth, fifth, and sixth columns of the table.

In connection with the well-known experiments and views of Prof. Rowland the figures thus obtained are of the highest interest. In order to exhibit the results of his experiments in the form of a curve which (as he believed) would be of finite dimensions, Rowland adopted the method of plotting the values of μ as ordinates against those of $\mathfrak{B}$ as abscissæ. The curve of μ thus obtained, after reaching a maximum for a moderate value of $\mathfrak{B}$ (about 5,000), fell very rapidly, and ultimately to all appearance in a perfectly straight line, towards the horizontal axis, which, however, was not quite reached. Rowland, therefore, assumed that the line would continue to be straight until it met the axis at a point the abscissa of which would indicate the greatest possible value of $\mathfrak{B}$ for an infinite magnetic force. He thus arrived at the conclusion that for ordinary bar iron the maximum of magnetic induction was about 17,500 units. For pure iron he thought it might reach 18,000, or even go above that.

Now, the magnetic force used in Rowland's experiments was very small, the highest value being only 64 C.G.S. units. The imaginary part of his curve therefore corresponds to values of $\mathfrak{H}$ ranging from 64 to infinity. A part of this exceedingly wide gap is filled by the author's experiments, which include values of $\mathfrak{H}$ up to 585, and a curve constructed from the values of μ and $\mathfrak{B}$ in the fifth and sixth columns of the table seems to throw much new light on the subject. It corresponds, of course, only with a portion of Rowland's curve, the lowest value of $\mathfrak{B}$ included in it being 7,390. Beginning with a rapid descent, it turns aside soon after the limit of Rowland's observations has been passed, and ultimately when $\mathfrak{B} = 19{,}800$ it has become almost parallel to the horizontal axis. We may conclude then that if $\mathfrak{B}$ has any ultimate limit at all, it is certainly very much higher than that which was assigned to it by Rowland.

There may, perhaps, be some doubt whether the expression used to connect W and $\mathfrak{T}$ is exactly applicable to the case of the divided ring, and small errors may possibly be introduced by the fact that the contact between the opposite faces was not quite perfect throughout. But apart from minute accuracy of detail, the general character of the results is entirely free from doubt, and would be quite unaffected by a very large margin of uncertainty in the expression. They show that the generally accepted ideas with regard to several important points need modification.

Thus it is not true that the lifting power of an electromagnet reaches a practical limit under a comparatively small magnetising force, and that even if excited by an infinite current it could not support a weight of 200lbs, per square inch of surface.

It is not true that the magnetisation of iron becomes sensibly constant when the magnetic force exceeds a certain moderate value.

And it is not true that the maximum of magnetic induction, if it exists at all, is represented by anything like so small a value as 18,000 units.

In conclusion, the author has to express his great obligation to Lord Rayleigh for much valuable assistance and advice in the preparation of this paper.

TABLE.

$\mathfrak{H}$	W	$\mathfrak{T}$	κ	μ	$\mathfrak{B}$

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 518, Vol. XVI.)

Substituting for u this last value, we see

$$\nabla^2 F = \frac{4\pi\mu}{\sigma}\left\{\frac{dF}{dt}+\frac{d\phi}{dx}\right\}+K\mu\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\},$$

thus in the dielectric the equation becomes

$$\nabla^2 F = K\mu\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\},$$

in the conductor

$$\nabla^2 F = \frac{4\pi\mu}{\sigma}\left\{\frac{dF}{dt}+\frac{d\phi}{dx}\right\}.$$

The equation for the dielectric shows that it represents a wave-motion propagated with the velocity $1/\sqrt{\mu}$; the numerical value of this velocity agrees very approximately with the velocity of light, and this led Maxwell to the theory that the changes in the structure of the dielectric which take place when the dielectric is polarised are of the same nature as those which constitute light. This theory, which is called the electro-magnetic theory of light, might almost as justly be called the mechanical theory of dielectric polarisation. Kirchhoff, in his paper, "Ueber die Bewegung der Elektricität in Drähten" (Pogg. *Ann.*, Vol. C. 1857; *Gesammelte Werke*, p. 131), was the first to point out that some electrical actions are propagated with the velocity of light. In this paper he considers the motion of electricity in wires whose diameters are small compared with their length. There are three things which have to be considered in this problem—(1) The self-induction of the electric current, and if the medium be taken into account, that of the polarisation currents in the dielectric. This self-induction produces very much the same effect as if the electric current possessed momentum. (2) The electrostatic action of the free electricity which tends to bring things to a definite state, and corresponds very much to the spring in a material system. Then, lastly, there is the electrical resistance, which corresponds to friction in an ordinary system. We see from the analogy that if the resistance be small enough, the electrical system will vibrate; if, however, the resistance is large, the electrical disturbance will be propagated in the same way as heat. Kirchhoff in his paper considers the propagation of electrical disturbance along a wire under various conditions; we shall only consider here one of these cases, that of an endless wire. In his solution Kirchhoff only considers the self-induction of the current flowing along the wire; he does not consider the effects in the surrounding dielectric. He shows that if e be the quantity of electricity per unit length of the wire, and

$$e = X \sin ns,$$

where s is the length of a portion of the wire measured from some fixed point, then X satisfies the differential equation

$$\frac{d^2X}{dt^2}+\frac{c^2 r}{16\gamma l}\frac{dX}{dt}=\frac{c^2}{2}\frac{d^2X}{ds^2},$$

where c is a quantity which occurs in Weber's theory, and is the velocity with which two charged particles must move if the electrodynamic attraction between them balances the electrostatic repulsion;

r is the resistance of the wire in electrostatic measure; $\gamma = log\ l/a$, where l is the length of the wire and a the radius of its cross section. The form of the solution of this equation depends on the magnitude of

$$\frac{32\gamma}{cr\sqrt{2}}nl.$$

If this quantity be large, the solution takes the form representing the propagation of a wave along the wire with the velocity $c/\sqrt{2}$. Weber's researches show that this velocity is very nearly equal to the velocity of light. If, however, the above-mentioned quantity be small, then the solution of the equation takes the same form as the formula which expresses the conduction of heat along the wire. We must not, however, take this to mean that the electric disturbance is propagated with an infinite velocity, so that if we had an infinitely delicate electrometer at a definite distance from the source of disturbance we could detect an electrification after an indefinitely short time, for it seems obvious that the electrical resistance cannot increase the velocity of propagation any more than the resistance of the air could increase the velocity of propagation of a disturbance along a line of particles connected by an elastic string. The conditions at the end help to determine the form of the solution, and these cannot make themselves felt until the disturbance has reached it; thus the heat form of solution probably only holds after a time from the commencement of the disturbance greater than the time taken by light to travel along the wire. If we take the case of a copper wire one square centimetre in area, we shall find that the wave form of solution will hold if the wire is not more than 100 miles in length, while the heat form will correspond to wires which are much longer than this. Kirchhoff's solution only refers to the propagation of a disturbance in a conductor, while Maxwell's refers to the propagation of such a disturbance in the dielectric.

Maxwell considers the effect of the motion of the medium on the electromotive force; he shows that the electromotive force parallel to the axis of x

$$= cv - bw - \frac{dF}{dt} - \frac{d\psi}{dx},$$

where u, v, w are the components of the velocity of the medium conveying electric action. Here ψ is not the electrostatic potential merely; it is equal, as Helmholtz has shown,* to the electrostatic potential plus the term

$$Fu + Gv + Hw.$$

We must remark here that u, v, w are the components of the velocity of the medium conveying the electric action, *i.e.*, the ether, and this need not necessarily be the same as the velocity of the dielectric.

Von Helmholtz's Dielectric Theory.

Von Helmholtz, in the paper† to which we have so often referred, considers the effect of the polarisation of the dielectric; he supposes that when an electromotive force X, parallel to the axis of x, acts on an element of a dielectric, it puts it into such a state that it produces the same effect as if there were electricity of surface-density x on the face $dy\,dz$ of the element, and an equal quantity of electricity of the opposite sign on the parallel face, x being given by the equation $x = \epsilon X$, the variations in the electromotive forces acting on the dielectric are supposed to produce the same effect as ordinary conduction currents whose components are $\dot{x}$, $\dot{y}$, $\dot{z}$, where x, y, z are the components of a vector quantity which in isotropic media is parallel to the electromotive force and equal to the product of ϵ and the intensity of the force. This agrees with Maxwell's assumption, provided $\epsilon = K/4\pi$, where K is the specific inductive capacity of the dielectric. If ϕ be the electrostatic potential of the free electricity, ψ the potential due to the polarisation of the dielectric, then Helmholtz shows that

$$\frac{d}{dx}\left\{(1+4\pi\epsilon)\frac{d}{dx}(\phi+\psi)\right\}+\frac{d}{dy}\left\{(1+4\pi\epsilon)\frac{d}{dy}(\phi+\psi)\right\}+\frac{d}{dz}\left\{(1+4\pi\epsilon)\frac{d}{dz}(\phi+\psi)\right\}=-4\pi E,$$

where E is the volume-density of the free electricity. The corresponding equation in Maxwell's theory is of the same form, provided $1+4\pi\epsilon = K$.

This relation seems inconsistent with the previous one; it may, however, be reconciled with it in the following way:—

The potential due to a quantity E of electricity at a point distant r from it is proportional to

$$\frac{E}{(1+4\pi\epsilon)r}.$$

* *Ueber die Theorie der Elektrodynamik; die Elektrodynamische Kräfte in bewegten Leitern*, "Crelle," LXXVIII., p. 309; "Gesammelte Werke," II., p. 745.

Digitized by Google

If ϵ_0 be the value of ϵ for air, the potential under the same circumstances in air is proportional to

$$\frac{E}{(1+4\pi\epsilon_0)r};$$

if, then, we define unit potential as the potential at unit distance from unit of electricity in air, the potential due to a quantity E in another medium will be

$$\left\{\frac{1+4\pi\epsilon_0}{1+4\pi\epsilon}\right\}\frac{E}{r}.$$

We see that this is equivalent to increasing the unit of potential, and therefore the unit electromotive force, $1+4\pi\epsilon_0$ times, so that if we use the new unit the equations will be

$$x=\frac{\epsilon}{1+4\pi\epsilon_0}X,$$

$$\frac{d}{dx}\left\{\frac{1+4\pi\epsilon}{1+4\pi\epsilon_0}\frac{d}{dx}(\phi+\psi)\right\}+\ .\ .\ .\ .\ .=-4\pi E.$$

These will coincide with Maxwell's equation if we make ϵ and ϵ_0 each infinite and put $K=\epsilon/\epsilon_0$.

Returning to Helmholtz's theory, if u, v, w are the components of the total current

$$u=p+\dot{x},\quad v=q+\dot{y},\quad w=r+\dot{z},$$

where p, q, r are the components of the conduction current.

Helmholtz puts

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=-\frac{d\rho}{dt}$$

where ρ is the volume-density of the free electricity, and if σ be the surface-density of the free electricity at any point of a surface separating two media, u_1, v_1, w_1; u_2, v_2, w_2, the components of the current in the two media, l, m, n the direction cosines of the normal to the surface drawn from the first medium to the second, then according to v. Helmholtz

$$l(u_1-u_2)+m(v_1+v_2)+n(w_1-w_2)=\frac{d\sigma}{dt}.$$

According to Maxwell the corresponding equations are

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0,$$

$$l(u_1-u_2)+m(v_1-v_2)+n(w_1-w_2)=0.$$

As it is in the difference between these equations that the difference in the theory really lies, it will be instructive to look at them from another point of view. We know of no way in which the quantity of free electricity can be altered except by electricity being conveyed by conduction currents to the place where the alteration takes place. Assuming, then, that the alteration in the density is caused by such currents

$$\frac{dp}{dx}+\frac{dq}{dy}+\frac{dr}{dz}=-\frac{d\rho}{dt},$$

$$l(p_1-p_2)+m(q_1-q_2)+n(r_1-r_2)=\frac{d\sigma}{dt}.$$

So that Helmholtz's equations taken in conjunction with these are equivaient to the condition

$$\frac{d\dot{x}}{dx}+\frac{d\dot{y}}{dy}+\frac{d\dot{z}}{dz}=0;$$

$$l(\dot{x}_1-\dot{x}_2)+m(\dot{y}_1-\dot{y}_2)+n(\dot{z}_1-\dot{z}_2)=0.$$

Thus on Helmholtz's theory the dielectric currents behave like the flow of an incompressible fluid, while on Maxwell's theory it is the total current which is the sum of the conduction currents and the dielectric currents which behave in this way.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due on the 30th inst. on the debentures of this company will be paid by Messrs. Barclay, Bevan and Co., of Lombard-street, E.C. The coupons must be left three clear days for examination.

THE ROYAL HOLLOWAY COLLEGE.

The 30th of the present month will be a red letter day in the annals of Egham, for then Her Majesty the Queen will open what is destined to become one of the most influential institutions in the United Kingdom, the Royal Holloway College for the Education of Women, a monument of practical benevolence of which it is perhaps not too much to predict that it will long survive those specifics by which the name of its founder has become a household word, and by the sale of which he raised his immense fortune. Had the deceased philanthropist consulted his own inclinations only it is more than probable that his wealth would have been devoted, we will not say to a better or to a more useful purpose, but at least to some object in the benefit of which a portion of the mass of mankind who constituted the principal *clientèle* by whom that wealth was created would have participated. This, however, will by no means be the case. The college, which is really a scheme of the deceased's wife, is to be dedicated to the higher education of women of the upper middle classes—a subject in which she took a deep interest—and will be all but self-supporting. Indeed, so far as we have been able to ascertain, the conditions of admission to the enjoyment of its privileges are essentially prohibitive to all except the well to do, notwithstanding that beyond the £600,000 which has already been spent in the purchase of the freehold, and in the erecting and furnishing of the institution, £100,000 has been left by way of endowment to it. For this reason we do not doubt that there will not be wanting many who, forgetting the homely adage that one should never look a gift horse in the mouth, will question the wisdom, if not the motives, of the donor. So far, the trustees who were left to carry out the project are to be congratulated on its achievement, in which neither labour nor money has been spared. Indeed, the edifice itself, which is situated on Mount Lee, the *demesnes* of which embrace about 95 acres of land of pastoral beauty unsurpassed perhaps in England, has been constructed on a princely scale of magnificence, satisfying at once all the claims of art and hygienic science. It is of the architecture peculiar to the period of the French Renaissance, being in the form of a huge parallelogram, divided by a central block, which forms it into two quadrangles in the interior. The entire structure is of red brick and Portland stone, the latter exhibiting some excellent specimens of ornamental masonry. Some conception of the size of the college may be gathered from the fact that it is about seven years since Mr. Martin G. Holloway laid its foundation stone, and that there are upwards of 1,000 rooms in it, providing accommodation for 250 students, with their teachers. In addition to these, there are a dining room, a library, a museum, recreation hall, and a chapel, the latter forming one side of the northern façade, and being decorated in the interior with some rich examples of fresco painting of sacred subjects, and of bas relief resembling in style what is to be seen in the Royal Palace at Fontainbleau. A valuable collection of paintings, bought at sales at various times by Mr. Holloway for £90,000, including some of the choicest works of the best known English masters, adorns the walls of the recreation hall, turning it into a veritable picture gallery not unworthy of a room in the national collection in Trafalgar-square. Such is a very imperfect outline of the luxurious manner in which the trustees have carried out the bequest committed to them. Not the least among the many advantages which the future residents at Mount Lee will possess will be an installation of the electric light, of which it is our more immediate purpose to speak. This has been entrusted to the well-known engineers, Messrs. B. Verity and Sons, of King-street, Covent-garden. The electric lighting of the college may be said to have been an afterthought of the trustees, for it is only a few weeks ago since that firm received the commission to carry out the installation. This they have done in a manner which reflects the highest credit on them. As at present arranged, only the principal portions of the establishment on the ground floor will be so illuminated, the rest being supplied with gas, but it is expected that eventually the whole of the building will be lighted by electricity. Provision is made now for between

Digitized by Google

600 and 700 incandescent lamps of the Swan-Edison type, of 10, 16, and 32 candle-power, fed by a couple of Edison-Hopkinson dynamos. These were made in America, and are the first of the kid that have been seen in this country, with the exception of the two that have been supplied to the Constitutional Club, now in course of construction in the Northumberland avenue. They are driven by a Davey, Paxman, and Company's horizontal compound engine. The machinery has been fitted up in a building erected on the grounds at a considerable distance from the college, and communicating with the latter by means of a tunnel, through which the leads are conveyed, by the aid of all the necessary appliances for effective insulation, to the main switch-board. From this the subsidiary circuits to the various parts of the building are supplied. A number of these circuits have been provided, no one of them carrying more than 25 amperes. In the tunnel alluded to a small line of rails has been laid for the purpose of carrying to and from the college the household supplies. The small trucks of the miniature line will in all probability be driven by an electric motor. As regards the fittings for the electric light we can speak only in terms of the highest praise. They are models of design and workmanship in brass. Indeed, they are mostly from special drawings from the pencil of the architect, Mr. Crossland, and belong to the pure Renaissance period. The library and museum, which are *en suite*, are furnished with sixteen standards 7ft. high, mounted on marble pedestals 4ft. high Each of these standards weighs over 2cwt. of brass, the whole being finished in gold ormolu. They carry six lamps, each of 32 candle-power, and are the finest and the most elaborate specimens of workmanship of the kind that we have ever seen. The recreation hall is lighted by five electroliers depending from the ceiling, which are also exceedingly elegant in pattern, whilst the brackets in the chapel are in perfect harmony with the richness of the rest of its decorations. In the dining hall there are twelve groups of six lamps each, fixed close to the ceiling, each group being under a celadon reflector. Silvertown wire is used throughout the entire installation, which we have no hesitation in saying, when it is completed, will be not only one of the largest but one of the prettiest in Great Britain.

THE TRANSFORMATION OF HEAT INTO ELECTRICAL ENERGY WITH BATTERIES, THERMOPILES, AND DYNAMO MACHINES.*

With batteries it is the heat generated by the chemical processes going on in them which is transformed into electricity. With thermopiles there is a direct transformation of heat into electricity. With dynamos it is work that is transformed into electricity, and this work is usually done by a steam or some form of gas engine.

In a battery the heat used is the difference of the heat evolved and absorbed in the various chemical actions which go on in it.

Thus, taking a Daniell battery, we have the heat given out in the formation of zinc sulphate mines that absorbed in the decomposition of the electrochemically equivalent amount of copper sulphate, or, what is the same thing, the heat given out in the union of zinc with oxygen minus that given out by the union of copper with oxygen.

We will consider as the available heat only that which is generated outside the battery. Thus, if we consume a certain amount of material in the battery, a certain part of the heat goes to warm the battery itself, owing to its resistance, and this heat is lost and cannot be made to do external work. Thus, if the current be A amperes, and the resistance of the battery R ohms, the work which goes to heat it per sec. is A^2R; and, if E be the E.M.F. of the battery, the work which is done outside the battery per sec. is in electrical units $AE - A^2R$. Now, $A = \frac{E-e}{R+R'}$, where e is the E.M.F. generated by the motion and R' the resistance of the external circuit. The ratio of the heat used in the external circuit to the whole heat given out by the battery, if we do not take into account local action and other causes of waste in the battery, is $\frac{AE - A^2R}{AE}$, or, substituting the above value of A, $\frac{E\,R' + e\,R}{E\,(R+R')}$. If $R = R'$ this becomes $\frac{E+e}{2E}$.

This last ratio is greatest when $e = E$. Then all the heat is used outside the battery; but then there is no current. We see from this that we may increase the ratio of the heat given out in the external circuit to that used in battery by increasing either R' or e; and that theoretically we may use very nearly the whole heat externally. The same reasoning applies to thermopiles and dynamos. In practice, however, there are other things to be taken into consideration. For particular practical cases, taking into account the actual material used up, the author gives the percentage 47·72 for a Daniell and 59·1 for a Bunsen.

In the case of thermopiles the percentage of heat available in the circuit is very small indeed. There we count as the heat employed the heat given out by the fuel actually burnt. For a pile of Rebicek, from data given by Herr Kayser in *Wied. Ann.*, only 0·16 per cent. of the heat. This was for 20 or 25 elements. For 50 large class elements the percentage was only 0·13.

In the case of Clamond's thermopile, taking data from "Müller-Pfaundler's Text-book of Physics," we get 0·057 per cent., and from N. Kayser's experiments 0·076 per cent. A Clamond thermopile heated with coke gives more favourable results. In this case we get 0·518 per cent. of the energy given out by the coke in electrical energy in the external circuit.

In Lord Rayleigh's comparison of a thermo-electric battery, consisting of German silver and iron with a perfect heat engine, he found that the latter would yield 300 times more electric energy than the thermopile.

It seems natural to suppose that the direct transformation of heat into electrical energy should be the most advantageous manner of making this transformation, and that at some future time thermopiles will acquire great practical value. The great waste of heat arises, of course, from the fact that, owing to the smallness of the surface, only a very small quantity enters the pile at all, and some of this passes by conduction to the cold junctions, or is radiated from the external surfaces of the elements.

We now come to dynamo machines, and as a working motor of such we are thinking here of a steam engine or a gas motor, and we shall compare the relations between the useful electric energy imparted to the dynamo machine, and the heat energy given out by the combustible consumed (coal or gas). We must not here alone regard the heat which passes into the water and makes it steam, but the whole heat which is given out by the combustible. We do not concern ourselves with the efficiency of the heat engine, but with that of the apparatus which converts the heat into electric energy, passing over the intermediate transformation.

In the case of a steam engine the calculation gives 3·2 per cent. of the heat used as being converted into electrical energy in the external circuit; in the case of a gas engine 5·85 per cent.

Hitherto we have concerned ourselves with the relation of the quantity of useful electrical energy obtained from the known quantity of heat employed in generating it by different methods, and we have shown that batteries give by far the greatest amount of electrical energy for the same quantity of heat. Thus they give ten times more than dynamo machines, and, if we speak of Clamond's thermopile with coal heating, 200 times more than thermo-electric batteries.

The relations will, however, be different if we have regard to cost. The heat used in batteries is the dearer, because here it is zinc, which is burnt, while in the other cases it is coal or gas. We will therefore look at the relation between the electrical energy obtained and the cost in the three cases.

To have the same relation with all sources, we will take the proposition to determine the cost of an hourly electric energy of 500 volt-amperes as given by batteries, thermopiles, and dynamo machines.

In a Daniell battery we take into account the cost of the zinc and sulphuric acid. The copper vitriol used need not be reckoned, as its cost is covered by the deposited copper.

In the case of thermopiles and dynamos there is the wear and tear of the apparatus, as well as the cost of the combustible used.

The following table gives the expense in the several cases. The wear and tear of the machinery is taken into account in the case of dynamos, but not in the case of thermopiles.

Name of Element.		Cost per hour of 500 volt-amperes.
Daniel Element		1·06 Mk
Bunsen Element		1·51 ,,
Rebicek Thermopile	Starpile	5·65 ,,
	Pile with straight fire-line	7·17 ,,
Clamond Thermopile	with gas-heating	16·03
	with coal-heating	0·42
Dynamo Machines	with steam	0·105
	with gas motor	0·25

These numbers show that the cheapest electric energy is given by dynamo machines which are driven by steam power.

The mark may be taken as the equivalent of 1/-.

* Abstract from an article by Wilhelm Peukert in the *Zeitschrift für Elektrotechnik*.

SOUTH KENSINGTON.

EXAMINATIONS OF THE SCIENCE AND ART DEPARTMENT.

The following are the questions set in Subject IX., Magnetism and Electricity, at the recent examination; examiners, Prof. Frederick Guthrie, F.R.S., and Prof. G. Carey Foster, F.R.S. :—

General Instructions.—(If the rules are not attended to, the paper will be cancelled).—You may take the elementary, or the advanced, or the honours paper, but you must confine yourself to one of them. Put the number of the question before your answer. You are to confine your answers strictly to the questions proposed. Your name is not given to the examiners, and you are forbidden to write to them about your answers. The examination in this subject lasts for three hours.

FIRST STAGE OR ELEMENTARY EXAMINATION.

(Time: Three Hours.)

Instructions.—You are not permitted to attempt more than eight questions. You may select only two in Magnetism, three in Frictional Electricity, and three in Voltaic Electricity. The value attached to each question is the same.

Magnetism.

1. If a compass needle is deflected when a steel bar is brought near it, how can you find out whether the deflection is due to magnetism already possessed by the bar, or to the bar becoming magnetised by the compass needle at the time of the experiment.

Answer. Bring first one end of the bar, and afterwards the other end, gradually near to the same end of the suspended compass needle. If attraction ensue in one case and repulsion in the other, we conclude that the bar was magnetised previous to the experiment. If attraction ensue in both cases we conclude that the bar was magnetised by the compass needle at the time of the experiment. If the deflection in the first case be a repulsion we may conclude, without further trial, that the bar was previously magnetised.

Remarks. If the bar were merely magnetised by the induction of the compass needle, the magnetising force being so small, the bar would only be temporarily magnetised, and, therefore, in each case the end presented to the compass needle would become oppositely magnetised to the end of the needle to which it was presented.

It is important that the bar should be brought gradually near to the compass needle, for if it were brought suddenly almost into contact with the needle it might, if magnetised so that the adjacent ends of the needle and bar were similar, have its magnetism reversed by the inductive action of the needle, and so show attraction instead of repulsion.

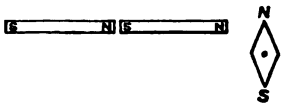
2. Two equal bars of steel, after having been equally magnetised, are kept for some years in a vertical position, one (A) with its south-seeking pole upwards, the other (B) with its north-seeking pole upwards. The bars are so far apart that they do not act on one another; which of the two bars would you expect to find had kept its magnetism best, and why?

Answer. The bar (A) would keep its magnetism better than the other.

For in this country, being entirely to the north of the magnetic equator, the earth's magnetic force acts in such a direction as to make the north-seeking end of a freely suspended magnetised bar dip downwards towards the horizontal, at an angle called the angle of dip, which varies from place to place, and it would act in the same way on the molecules composing the two bars, tending in each case to produce a north-seeking pole at the lower end of the bar and a south-seeking pole at the upper end. Thus the earth's action would assist (A) to retain its magnetism, but would tend to reverse the magnetism of (B).

3. You have given to you two rods, one of soft iron, the other of hard steel; also a compass needle and a bar magnet. Describe experiments with the things provided whereby you could find out which was the iron and which the steel rod.

Answer. Lay the bar magnet on a table, and place one of the bars to be tested close to, or even in contact with, the magnet S N, and in the same straight line with it. To the end of the bar remote from the magnet bring near the end of the suspended compass needle similar to the pole of the magnet adjacent to the bar; observe whether the compass needle be attracted or repelled. Now, without removing the bar magnet or the compass needle, replace

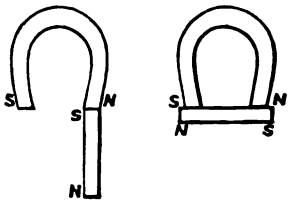


the first bar by the second, and again observe whether attraction or repulsion ensue.

It will be found that in one case there will be attraction and in the other repulsion. The one which attracts the needle will be the bar of hard steel, and the one which repels it will be the bar of soft iron.

Explanation. The soft iron becomes magnetised by induction while in the presence of the bar magnet, but the effect of the bar magnet on the hard steel will be very small, extending only to the molecules of the bar in immediate proximity to the magnet, and therefore the bar remains practically unmagnetised.

4. A piece of soft iron, placed in contact with both poles of a horse-shoe magnet at the same time, is held on with more than twice the force with which it would be held if it were in contact with only one pole of the same magnet. Why is this?



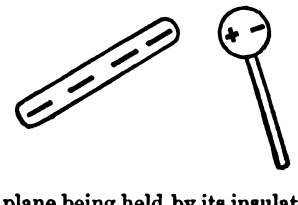
A.—When the piece of soft iron is placed in contact with one pole of the horseshore magnet it becomes magnetised by the induction of the pole with which it is in contact. When the piece of soft iron is in contact with both the poles of the horseshoe magnet it is subject to the inductive action of both the poles of the magnet, and becomes more strongly magnetised. The force with which it is attracted by each pole is therefore greater than that with which it was attracted by the single pole in the first case, so that the whole force of attraction of the two poles on the soft iron bar is more than double the force of attraction of the single pole.

Frictional Electricity.

5. A stick of sealing wax, held in the hand and rubbed with dry flannel, is found to become electrified. A brass rod after being treated in the same way shows no electrification. How do you account for the difference?

A.—The stick of sealing wax is a bad conductor of electricity, and therefore the electricity produced upon its surface is retained. The brass rod, on the other hand, is a good conductor, and being in contact with a portion of the human body, which is also a conductor, the electricity flows away as fast as it is produced upon the surface of the rod.

6. A stick of sealing wax, having been rubbed with flannel, is found to be negatively electrified. How, by means of it, would you charge a proof plane with positive electricity?



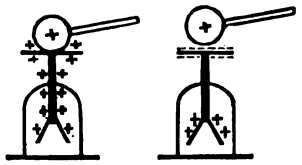
A.—The proof plane being held by its insulating handle, bring the negatively electrified sealing wax close to its metallic portion (or even in actual contact with it, for the sealing wax being a non-conductor, will not part with an appreciable quantity of its electricity to the proof plane). The proof plane then becomes electrified by induction, positively on the side near the sealing wax, negatively on the further side.

Connect the proof plane while in presence of the sealing wax to the earth by touching it with the finger, or otherwise, in order to remove the negative electrification, and remove the finger. If the proof plane be now removed from the inductive action of the sealing wax it will remain positively electrified.

7. If an electrified piece of metal is made to touch a gold leaf electroscope, the leaves separate, and, on taking the metal away, they remain separate. But if the electrified metal is only brought

Digitized by Google

near to the electroscope, and then taken away, the leaves separate when the electrified metal is near, but fall together when it is taken away. Why is there a lasting effect on the gold leaves in one case and only a temporary effect in the other case?

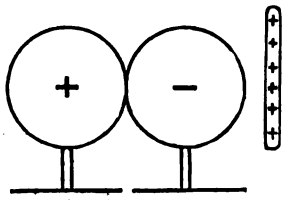


A.—In the first case, the electrified piece of metal (which must, of course, be held by an insulating handle) communicates, by conduction, a portion of its charge to the electroscope, and the charge so communicated to the electroscope remains after the piece of electrified metal is removed.

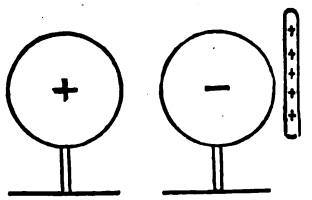
In the second case, the plate of the electroscope and the upper part of the metal rod which carries the gold leaves become, by the inductive action of the piece of electrified metal, oppositely electrified to it, while the gold leaves and the lower part of the rod become electrified similarly to it. The electroscope, however, receives no absolute charge, and therefore the leaves fall together again when released from inductive action by the removal of the electrified body.

The figure is drawn for the case of positive electrification of the piece of metal.

8. Two insulated metal spheres are brought so as to touch one another. A positively electrified glass rod is brought near to one of the spheres, and, while it is there, the other sphere is taken away. The glass rod is now taken away. On bringing the spheres near together again, a spark passes between them. Give the reason for this.



A.—By the inductive action of the positively electrified glass rod the nearer sphere becomes negatively electrified and the further one positively.



If the spheres be so parted while under the inductive action of the glass rod, and the rod then removed, their electrifications remain unchanged.

If the spheres be now brought together in the absence of the glass rod, there will be, since they are oppositely electrified, a discharge of electricity from one to the other, which accounts for the park.

9. To protect a gold-leaf electroscope from being acted on when an electrical machine is at work near it, it is sufficient to cover the electroscope with a thin cotton cloth. How is this?

A.—Since the electroscope is protected from the inductive action of an electrical machine near it by covering it with a cotton cloth, the cloth must be a conductor, as would be the case unless it were perfectly dry, and then it would not protect the electroscope from the action of the machine.

The electroscope may therefore be considered as enclosed within a hollow conductor, and the electricity upon a hollow conductor under the inductive action of *external* electrified bodies distributes itself upon the surface of the conductor in such a manner as to exert no electrical action upon any bodies enclosed within it.

Remarks. We may note that, whether the enclosed bodies be in electrical communication with the hollow conductor or not, they will be protected from the action of any electrified bodies external to the hollow conductor, and we also know that, even if an absolute charge were given to the hollow conductor by conduction from any electrified body, the charge so given would also distribute itself over the surface of the conductor in such a manner as to exert no electrical action upon bodies enclosed within it.

(To be continued.)

CRICKET.

EASTERN TELEGRAPH COMPANY v. ANGLO-AMERICAN TELEGRAPH COMPANY.

The second of the Inter-Telegraph Companies' cricket matches came off on Saturday last at Brockley, and resulted in an easy victory for the Eastern Telegraph Company. Very little description of the play is needful. The Anglo Company, having won the toss, decided to go in first, but were unable to make any stand against the very fine bowling of Messrs. J. G. McMillan and Alexander Jack, the former securing seven wickets in six overs at a cost of two runs. This is really fine bowling. Mr. McMillan deserves full credit for his performance. The innings closed for eight. After a short interval the Eastern Company commenced their innings with Messrs. Palmer and McMillan, who very soon put the result of the match beyond a doubt. Messrs. M'Donald, Captain Greey and Couper, all batted well, and the innings closed for 77. The Anglo Company then went in for their second innings, and after about an hour's play were disposed of for 27 runs, Mr. Couper being the most successful bowler. Messrs. Langley, A. Duncan, and Edwards were the only ones who made anything of a stand, contributing the best part of the 27 runs for which the innings closed. This left the Eastern Company victors by an innings and 42 runs. The following is a detailed list of the scores:—

ANGLO-AMERICAN TELEGRAPH COMPANY.—*First Innings:* A. J. Willis, c. Gray, b. McMillian, 0; G. Duncan, b. McMillan, 0; A. Duncan, b. McMillan, 0; R. J. Edwards, b. McMillan 0; S. R. Bartrum, b. McMillan, 0; H. Bergamin, b. McMillan, 0; C. C. Afflex, b. A. Jack, 1; J. Mountford, b. A. Jack, 1; A. G. Reynolds, b. A. Jack, 0; C. W. Langley, c. Grey, b. McMillan, 0; F. Green, not out, 1; extras, 5. Total, 8.—*Second Innings:* A. J. Willis, c. A. Jack, b. Couper, 0; G. Duncan, b. A. Jack, 3; A. Duncan, b. Couper, 4; R. T. Edwards, c. Couper, b. McMillan, 6; S. R. Bartrum, b. Couper, 1; H. Bergamin, c. Greey, b. McMillan, 0; C. C. Affleck, b. Couper, 0; J. Mountford, b. A. Jack, 2; A. G. Reynolds, b. Couper, 1; C. W. Langley, c. Green, b. McMillan, 7; F. Green, not out, 0; extras, 3. Total, 27.

EASTERN TELEGRAPH COMPANY (LIMITED).—*First Innings:* J. G. McMillan, b. Duncan, 10; T. J. Palmer, run out, 4; C. Hensman, b. Duncan, 2; G. McK. Munro, c. Willis, b. Duncan, 6; W. Macdonald, b. Reynolds, 22; Capt. R. Greey, b. Reynolds, 14; G. C. Jack (captain), l.b.w., b. Duncan, 0; W. Couper, l b.w., b. Affleck, 14; T. Richardson, b. Affleck, 0; A. Jack, c. Reynolds, b. Affleck, 0; E. D. Payne, not out, 0; extras, 5. Total, 77.

NOTES.

PERSONAL.—Mr. Sydney Evershed has joined the staff of Messrs. Goolden and Trotter, electricians, Westminster.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 25th ult. amounted to £2,661.

ELECTRO-PHOTOGRAPHY.—M. Tommasi has found that the silent electric discharge produces the same effect upon sensitive photographic plates as do the ultra-violet and violet rays of light.

ELECTRIC TRAMWAYS.—Owing to the success of the Blackpool tramway, a company is in active formation for working Mr. Holroyd Smith's patents relating to the electrical working of tramways.

SWISS EXHIBITION.—It is proposed to hold next year at Geneva, on the occasion of the federal shooting competition, an exhibition devoted to electrical science and to the decorative and fine arts.

ELECTRIC LIGHT IN FRANCE.—At Bourganeuf, near Brest, the electric light has recently been introduced. The motive power is supplied by water, the installation giving the greatest satisfaction to the inhabitants.

TELEGRAPHIC TARIFF.—The French Senate on Tuesday approved the Telegraphic Tariff Convention concluded at Berlin on 9th September, 1885, and the Anglo-French Telegraphic Arrangement of 11th May last.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 25th ult. were £2,049, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE MIRROR GALVANOMETER.—The *Centralblatt für Elektrotechnik* complains that in the Catalogue of the Inventions Exhibition Dr. Lodge attributes the invention of the mirror-galvanometer to Sir W. Thomson. It claims this invention for Gauss.

ELECTRIC LIGHT AT EASTBOURNE.—Tenders are being invited by the town council for electric light and gas fittings for the new town hall. Persons wishing to tender are to send their names to the architect, Mr. W. T. Foulkes, 100, Colmore-row, Birmingham, by 15th July.

A SIGN OF THE TIMES.—Last week the Lanark Town Council, which is one of the largest shareholders in the Lanark Gas Consumers Company, decided to oppose a proposal to erect a new gasholder at a cost of £1,200, on the ground of the extension of electric lighting in this country.

A NEW TELEGRAPH LINE.—A new line has just been built in the Republic of Colombia between the cities of Manizales (State of Antioquia) and Cantago (State of Cauca), which gives communication to two other cities; but the most important feature is that it opens two routes from the capital to the cable line at Buenaventura.

SOCIETY OF ARTS.—The Society of Arts *conversazione* will be held, by permission of the Royal Commission, at the Colonial and Indian Exhibition, South Kensington, on Friday, the 16th July. There will be no admission to the Exhibition on this evening, except by special ticket, and no tickets can be purchased at the Exhibition.

ELECTRIC LIGHT IN LEEDS.—Mr. Wilson Hartnell, of Leeds, has obtained an order to light by electricity the large flour mills of the Leeds Industrial Co-operative Society. The installation will consist of 200 incandescent lamps, with fittings of the latest type. Another order has been secured by Mr. Hartnell for an installation at Dewsbury, where the Otto gas engine will be the motor.

NEW ELECTRIC TRAMWAY CAR.—Experiments are being made at the Schwortzkopff Works, in Berlin, with a new electric tramway car. The batteries are placed before and behind the platform, and take up little space, so that there is plenty of room for standing. The car has eight wheels, which is rather a disadvantage in getting over curves, but the trials so far have had good results.

STREET OWNERSHIP.—A New Orleans paper says that street car companies own only the surface of such streets as they choose to occupy. Below the surface, gas and waterworks companies are the sole proprietors. Above, the wire concerns —such as telegraph, telephone, and electric companies—are supreme. Any other odd space that may happen to be about is used by the city for storing dirt.

CABLE BETWEEN CANADA AND AUSTRALIA.—Instructions have been sent (says *The Times*) by the Dominion Government to Sir Charles Tupper, the High Commissioner for Canada in London, to confer with the Australian Agents-General concerning the establishment of cable communication between Australia and the Canadian Dominion, and to ascertain the amount of the annual subsidy which the colonies would guarantee.

ELECTRIC LIGHT IN PARIS.—The members of the Congress of the Société Technique de l'Industrie du Gaz have recently been paying a visit to the laboratory of the electric installation in the Rue Appert, Paris. M. D. Monnier conducted the visitors through the building, and they were loud in their praise of the Edison lamps, as well as of the Cance arc lights, the absolute steadiness of which they were obliged to acknowledge.

LIGHTING AT THE ROYAL BOTANIC SOCIETY'S FETE.—On Wednesday last, at the annual *fête* of the Royal Botanic Society, Regent's Park, a dining table was shown by Dick Radcliffe and Co. having a miniature lake in the centre, with fountains playing, and water lilies carrying small incandescent lamps. Tiny lamps were also distributed about the moss in a grotto, simulating glowworms. The current was supplied by a primary battery.

FRICTIONAL ELECTRICITY.—A suggestion has been made to utilise the electricity so freely obtained in many industrial operations by means of a secondary generator. The electricity is to be collected by means of brass points connected to continuous or Leyden jars, from which it is discharged through a long coil of fine wire, forming the primary, the secondary being of thick wire from which it is hoped to get the electricity for use at a low potential.

NEW AUTOMATIC SWITCH.—M. Allard, secretary to the Belgian Electrique Company, who invented the switch for putting into circuit any given number of secondary batteries, so as to regulate the speed of the electric tramcar, is now perfecting an automatic switch for instantaneously throwing into circuit the current from secondary batteries on that from a dynamo being thrown out. In the case of electric lighting, the interruption is so momentary as scarcely to be noticed.

BLACKPOOL ELECTRIC TRAMWAY.—The audit of the books shows, for the half-year ending with May, that the working expenses are only half that of horses on the most economically worked lines, even allowing 10 per cent. for interest on capital, and 15 per cent. for depreciation, because all the generating plant is duplicated. If the electrical working of the Blackpool tramway be compared with the working by horses before the

Digitized by Google

electrical plant was ready, it will be found to cost only 25 per cent. of the latter.

LABORATORIES FOR PARIS.—The International Society of Electricians has decided upon building laboratories for the use of physicists in Paris. They will be established in the grounds of the old Collége Rollin, granted by the City of Paris, in the vicinity of the school of Practical Physics, recently erected by the Municipal Council. The funds will be supplied by public subscription, a contribution from the society, and a sum of 360,000 francs, which is the surplus of the last electrical exhibition organised by M. Cochery.

THE PATENT OFFICE LIBRARY.—We are requested to state that the Free Public Library, at the Patent Office, 25, Southampton-buildings, Chancery-lane, W.C., is now open to the public daily from 10 a.m. to 10 p.m., instead of, as heretofore, from 10 a.m. to 4 p.m. This library, in addition to the specifications, indices, and other publications of the Patent Office, contains a large collection of the leading British and Foreign scientific journals, *transactions* of learned societies, and text books in the various departments of science and art.

LONG LIFE OF INCANDESCENT LAMPS.—The longevity of the Swan incandescent lamps on the Great Eastern Company's steamer, "Norwich," has already been referred to. Unfortunately, the lamp which the chief steward placed in his cabin for observation has been broken by accident; but there are some in the saloon burning as brightly now as when they were first placed there three years ago, having lasted over six thousand hours of actual use. Moreover, not a switch has given out, even those placed in the cabins at the command of passengers.

ELECTRICITY ON THE STAGE.—In the second part of "Faust" the Homunculus, as is known, presents himself. Earlier this being was painted on a glass bottle, in which a petroleum lamp burnt. Now they have made trial of an electric Homunculus at the Court Theatre in Hanover. The body is formed out of transparent red silk, and is illuminated by two little incandescent lamps, one of which is in the head. A little six-celled chromic-acid battery, fastened under the glass globe, serves as the source of the current. The effect is much better than with the old contrivance.

DOMESTIC LIGHTING IN BRUSSELS.—The Belgian "Electrique" Company has taken over the premises in the Rue Zérézo, lately occupied by the Societé Générale d'Electricité, which will in future direct its energies chiefly to lighting in the provinces of Belgium. The "Electrique" Company, whose tramcar worked by accumulators took the first prize at the Antwerp trials, has arranged to light several *cafés* and private houses in a whole district near the Northern Terminus. At present contracts are made in each case; but, after the first year's working, the current will be charged by meter.

LIGHTING OF THE GRAND' PLACE AND HOTEL DE VILLE, BRUSSELS.—On Saturday the Belgian Society of Engineers visited the temporary installation for lighting portions of the Hôtel de Ville, when they were made acquainted with the comprehensive scheme for illuminating the whole of that magnificent Gothic pile, and also the Grand' Place adjoining. The latter is now lighted on alternate evenings by two arc lamps mounted on high masts, and by two clusters of intensive gas lamps; but even gas engineers acknowledge that the former is more effective, while it seems that the difference in cost is not great.

SHIP LIGHTING.—On account of the appreciation by the passengers of the incandescent lighting on the Great Eastern Company's steamers "Norwich" and "Ipswich," two more of their vessels, the "Adelaide" and the "Claude Hamilton," have lately been fitted throughout with incandescent lamps driven by Crompton dynamos; and the "Princess of Wales" and "Lady Tyler" are to be similarly treated. A new twin-screw steamer, to carry 475 passengers, is being built for the Great Eastern Company by Earle's Shipbuilding Company at Hull, and is to be lighted fore and aft on the incandescent system.

AMPÈRE'S RULE.—In a letter to the last number of our contemporary, *Nature*, Mr. G. Dähne, of Dresden-Striesen, says:—"There is another rule, published by Pfaundler, if I am not mistaken, which is far simpler, as it does not compel the imagination to fancy movements and actions of the human body which it in reality never could perform:—'Follow the direction of the current in moving the right hand along the wire, but holding it so that the stretched fingers are parallel to the wire, and the palm is turned towards the north pole of the magnet. The outstretched thumb then gives the direction in which the north pole will be deflected.'"

KILLING DOGS BY ELECTRICITY.—Under this title, the *Electrical World*, of New York, describes a method adopted by the Kimberley Borough Council, on the recommendation of their electrician, Mr. R. L. Cousens, for despatching unclaimed dogs in a more painless manner than by poison. The dog is put into a box, with the fore paws on one moistened copper plate, and the hind paws on another. The plates are put in the circuit of a Brush dynamo, which maintains some electric lamps. When the box is closed, the current is sent through the dog, killing him instantaneously. On one occasion 23 dogs were killed in less than the same number of minutes.

ST. VINCENT.—A valued correspondent writes:—"Things every day getting more civilised at St. Vincent. Not only does the telegraph staff, which, by the way, numbers on its rolls seventeen fine healthy young fellows, possess a lawn tennis court, a theatre, a number of horses from the neighbouring island of St. Thiago, and a sanatorium perched high on the mountain, but an enterprising firm, Messrs. Miller, have introduced the electric light on their coal wharves. I could learn no particulars of the installation owing to the exigencies of time, but the light shone out over the bay at night with great effect, quite eclipsing the feeble ray from the lighthouse on Bird Rock."

LIGHTING IN SWEDEN.—We learn from *L'Ingénieur Conseil* the following particulars of the lighting arrangements for the little town of Hernosand, in the North of Sweden. The installation is proportional to the number of inhabitants—only 4,000; but it is encouraging to find such enterprise in so small and out-lying a town, situate on an island in the Gulf of Bothnia. A Thomson-Houston dynamo is driven by a waterfall about two miles from the town, and maintains 27 arc lamps of 1,200 candle-power each. The whole installation cost £1,120; and, estimating at £100 per annum the expenses of maintenance and supervision, the saving will be 25 per cent. of the former cost for lighting.

ELECTRIC LIGHTING IN BRUSSELS.—The old Temple des Augustins, which will continue to be used as the central Post Office until the new building begun on the site of the former Mint is completed, has, since Saturday last, been lighted by four arc lamps, two sun lamps, and several incandescents. The dynamo is driven by a 46 horse-power compound engine, with steam reservoir and Rider gear, made by Bollinckx et Cie, of Brussels. They are largely using this type of engine for electric lighting, and, strange to say, have gone back to the old Watt governor, but with extra heavy balls, finding that it

Digitized by Google

preserves a more constant speed than many of the newer governors.

LONG DISTANCE TELEPHONY.—M. Van Rysselberghe is now taking a well-earned rest in Brussels from his labours in establishing telephonic communication at long distances on the American Continent, whither he will shortly return. He has succeeded in holding distinct conversation between Buenos Ayres and Santa Fé, a distance of 500 kilometres, or 310 miles; between Santa Fé and Martin Garcia, 570 kilom., or 353 miles; Buenos Ayres and Rosario, 350 kilom, or 217 miles; as well as many other lines of less distance. Except in the Santa Fé and Martin Garcia line, 50 kilometres, or 31 miles, of which is a submarine cable, the persons conversing were able to distinguish each other's voices.

SALE OF ELECTRICAL PLANT.—We have received from Messrs. Wheatley Kirk, Price, and Goulty, of 52, Queen-Victoria-street, a catalogue of the electrical plant and fittings forming the surplus stock of the Edison and Swan United Electric Light Company (Limited), to be sold by auction at 67A, Cow Cross-street, E.C., on the 7th, 8th, and 9th inst., consequent upon the removal of the manufacturing department of the company from Newcastle to the metropolis, and their change of offices from Holborn to 14, Albert-mansions, Victoria-street, S.W. Electricians, ship owners, engineers, &c., will find at the sale every species of electrical apparatus, and will doubtless carry off some cheap purchases.

A RAPID INSTALLATION.—At the Grand Hotel, Brussels, recently, M. Allard, secretary to "L'Electrique" Company, asked some friends to join him at dinner. They knew he was not lighted electrically, and accepted on condition that the dining room should be so illuminated. He accepted the condition, though it was then a quarter past four, and the dinner was fixed for half-past six. He telegraphed to the works for a dozen 5-kilo. Julien accumulators, weighing together 60 kilogrammes, or 132lb., with instructions for a man to rig up six 10-candle lamps on the gaselier, with the leads of course anyhow. The guests were taken aback on entering to find the *salle à manger* brilliantly illuminated with an installation good for ten hours.

TELEPHONE CHARGES.—A meeting of business men, says the *Manchester Examiner*, was held on June 24 at the Manchester Cotton Waste Exchange to consider the charges of the Lancashire and Cheshire Telephonic Exchange Company. It was stated that subscribers had two grievances—firstly, that the present subscription of £20 was too high; and, secondly, that the company were now enforcing an additional subscription of a guinea a year for the use of the telephone boxes on the Exchange. The formation of a new company, on the system of Prof. Thompson, was suggested by the chairman, Mr. George Hahlo. A committee was appointed to lay the views of the meeting before the directors of the company, and to take such action as was deemed necessary.

NEW RESISTANCE SWITCH.—The difficulty connected with resistance coils lies in the fact that when they are used in series, and only a small final resistance is required, while large currents are employed, the passage through a short resistance tends to overheat it. If used in parallel, in order to obtain a large resistance through a single coil, a considerable number and weight of coils must be employed. Mr. Holroyd Smith has devised a switch whereby the same coils with the same terminals and continuous movement in the same direction may be used first in series and then in parallel, or *vice versâ*. If the switch be employed for putting in resistance, the coil is used first in parallel and then in series; but, if for taking out resistance, first in series and then in parallel.

ELECTRIC TRACTION.—Writing on this subject, our contemporary, the *Echo*, says: "The mischief done by the unwise rush for speculating schemes in connection with new inventions is well exemplified by the present position of practical electricity. Capitalists will not look at schemes for electric lighting, a department in which they have been severely bitten, and they carry their dislike into other departments, and will not support schemes for providing electric traction, preferring, rather, to support the 'cable' tram lines. Yet, while electric lighting, so far as the public service is concerned, never had much chance in this country, with gas at three shillings, it is probable that electric traction would pay well on many tram lines; certainly it is more promising than the resuscitated cable system."

AN ELECTRIC LOCOMOTIVE.—Messrs. E. M. Bentley and W. H. Knight have designed an electric locomotive for light passenger work, to be constructed at the Rhode Island Locomotive Works, U.S.A. The *Electrical World* says that it is of standard gauge, has a 12ft. wheel base, and weighs about 22 tons, the weight being evenly distributed over the six 68in. wheels. The motor armatures, 36in. in diameter, exert a force of 500,000 watts upon the wheels, which are all coupled, without the intervention of gearing. The engine is fitted with electric head lights, bells, and brakes, in addition to electric connections for incandescent lamps and continuous brakes throughout the train. It has no reciprocating parts, and is equally well adapted for use with overhead, surface, or sub-surface connection with the central power station of the line.

THE TELEPHONE IN SOUTH AFRICA.—In St. Paul de Loanda, the capital of the Province of Angola, a Portuguese possession on the South West Coast of Africa, there is an excellent and economical telephone system. The whole of the Government offices and a number of private houses are connected with a central office and with the terminus of the telegraph system, which penetrates some 200 miles into the interior. The telephone apparatus used is a modification of the Blake transmitter and Bell receiver; and the prices charged are very moderate, *i.e.*, about £4. 10s. for installation, and about £6 per annum subscription. The system works very well indeed, and is highly appreciated by those who had formerly to employ the expensive Maxilla as a means of locomotion, or plod through the sand-laden streets of Loanda. There are already sixty-one subscribers.

SOLID ELECTROLYTES.—At the meeting of the Physical Society, held on June 12, a voltaic cell with a solid electrolyte was exhibited by Mr. Shelford Bidwell. Its construction is as follows:—Upon a plate of copper is spread a layer of quite dry precipitated sulphide of copper; if on this a clean plate of silver be placed, and the cell joined up to a galvanometer, a slight deflection is observed due to the unavoidable presence of moisture. If, however, the silver plate be covered with a slight film of sulphide of silver, by pouring on it a solution of sulphur in bisulphide of carbon, and evaporating the free sulphur by heat, and then placed with the prepared side down as before, a deflection is obtained far greater than, and in the opposite direction to, the former. The resistance of the cell was very great, but was enormously reduced by compression. The E.M.F. was about ·07 volt.

TELEGRAPH POLES. — Mr. Greenhill, in a paper on "Creosoting," read before the Institution of Civil Engineers, Ireland, gives the following information as to the system for the preservation of telegraph poles for Government. Creosoting is universally adopted, all other systems having fallen into disuse. It is reported that, to obtain the specified quantity of 10 pounds of creosote injected per cubic foot, the fine skin

Digitized by Google

which grows upon the pole just underneath the bark must be carefully removed by planing. Native larch and other timber is reported to have failed, and no other timber but Baltic red-wood well seasoned and then creosoted is used. All the sundry processes for the treatment of timber with salts of zinc, copper, and mercury seem to have fallen into disuse owing to the corrosion of the receiver and apparatus by the materials employed, a defect not possessed by creosote, and also to the solubility in water. Oil paint in many cases, when used out of doors, conceals rather than prevents decay.

THE TELEPHONE IN TROWBRIDGE.—The New Telephone Company (Limited) have, according to the *Trowbridge Chronicle*, completed their labours in fixing the telephone to Mr. W. Walker's mills, whereby the four mills in different parts of the town are now all connected. "The telephone is Prof. S. P. Thompson's patent, and, unlike other companies, this company sell theirs outright, demanding neither rentals nor royalties; and this system enables persons to talk through miles of line. The wires are carried over the streets on properly insulated supports, and connect the four mills in telephonic communication with each other. We had an opportunity of testing the installation, and could converse freely from the Home Mills to either Yerbury-street, Duke-street, or the Stone Factory; in fact, the articulation was so clear that we could tell who we were conversing with. The entire arrangements have been carried out by Mr. Samuel Diplock, engineer, of London and Trowbridge, who, we understand, has other contracts to carry out under the same system."

BLEACHING BY ELECTRICITY.—This process, which has been brought to commercial success by M. Hermit, is about to be introduced into this country by the inventor, who has appointed as his sole licensees Messrs. Paterson and Cooper, who are commencing the manufacture of the requisite plant on a scale commensurate with the expected demand from the bleaching works of the United Kingdom. One great advantage claimed for the electric process is that a saving in cost is effected of about 50 per cent as compared with the use of bleaching powder, and another is that it does not involve that danger to the tissues operated upon which exists in the present system owing to the presence of lime in the bleaching solution. The working of the apparatus is also very simple, and by means of an ammeter and voltmeter it can be regulated and controlled at any distance from the bleaching tanks. A solution of chloride of magnesium is submitted to the action of an electric current with an E.M.F. of 4 volts through platinum electrodes, causing chlorine to be liberated, and at the same time oxygen from the water, a cycle of changes taking place which ultimately result in the regeneration of the chloride of magnesium.

SHAVER'S MECHANICAL TELEPHONE.—Mr. George F. Shaver has established an exchange station at New York in accordance with his system of mechanical telephony. On entering the station the line is split, one branch being attached at each hole round the bottom of a circular rack, where it is permanently fixed. The other branch of the same line is then attached to a small block placed directly over the lower terminals, and capable of sliding freely up and down between the vertical rods. All the upper terminals are at the same height when the lines are not in use; and it is only when cross connection is made between any two of them that the blocks are lifted to the height of the arm carrying the pulley for tightening the connecting wire. The work of the operator in communicating with the subscriber is facilitated by the use of hand telephones, provided in the rear with two brass strips, hooked at the top so that the instrument can be hung at any point upon a circular hoop running round the interior of the frame. The diaphragm has attached to it a small length of wire hooked to the terminal of the line; and the operator, by gently pressing forward the handle of his telephone, creates a tension on the diaphragm which allows him to communicate with the subscriber. Though some of the lines are about three-quarters of a mile long, the articulation is said to be very satisfactory.

COST OF ELECTRIC LIGHTING.—Writing to a recent number of the *Revue Industrielle* on this subject, M. Delahaye gives some interesting facts. He says that at the Essones paper mills there are 300 Edison lamps of the "A" type, driven by steam power, and the cost per lamp per hour is declared to be not more than 0·0175fr., in consequence of which the mill-owners have decided to discontinue the use of gas. In another paper mill in Central France, possessing water power, the cost of incandescent lighting for the past eighteen months has been determined to be 0·0103fr. per lamp per hour. Upon this basis the incandescent electric lighting in question compares with gas at about 10c. to 15c. per cubic metre, or 2s. 3d. to 3s. 4½d. per 1,000 cubic feet, which is considered to be an unremunerative price for French provincial gas supply. M. Delahaye is very sanguine of even obtaining better results. If the new Edison 2·5-watt lamps are practically successful in working, he points out that a horse-power will supply 14 lamps of 20 candle, instead of as now only eight lamps of 16 candle-power. A Russian electrician, M. Lodyguine, is also reported to have made lamps yielding a candle-power for every 1·6 watt of electrical energy. At this rate a horse-power should supply a score of lamps of 20 candle illuminating value. M. Delahaye is not quite satisfied that the new pattern lamps of which he speaks will really do all this; but he says that they may do so.

ELECTROLYSIS.—At the last meeting of the Chemical Society a paper was read by Prof. H. McLeod, F.R.S., on "The Electrolysis of Aqueous Solutions of Sulphuric Acid, with special reference to the forms of Oxygen obtained," of which the following is an abstract:—"The experiments were instituted to determine the quantity of ozone that can be obtained by electrolysis. The negative electrode consisted of a small platinum plate, and the positive of a tube containing mercury and with fine platinum wires of 0·45 mm. and 0·027 mm. in diameter fused into the glass. Several wires were used, the total length being about 6 mm. The electrolysis was carried out in a U-tube surrounded by ice and water; the hydrogen was collected over water, and the ozonised oxygen passed through a tube containing a solution of potassic iodide, the oxygen being afterwards collected. The quantity of ozone was determined by acidifying the potassic iodide solution and decolorising by a standard solution of sodic thiosulphate. In the electrolysed acid an oxidising substance is present which is not hydroxyl, but is probably Berthelot's persulphuric acid. The amount of this 'active oxygen' was found by adding potassic iodide to the liquid and decolorising by the solution of thiosulphate. The electric current was measured by a tangent galvanometer, and the dimensions of the wires of the positive pole were determined; from these data the intensity of the current was calculated. Acids were used of relative densities varying between 1·025 and 1·7. The maximum quantity of ozone was obtained with solutions about 1·075 or 1·1 in density, the electrolytic oxygen containing about 16 or 17 per cent. of its weight of ozone. The maximum quantity of 'active oxygen' in the oxidising substance referred to was produced with acids about 1·2 to 1·25 in density, the proportion being 16 or 17 atoms to 100 atoms of hydrogen."

CYRUS FIELD V. LABOUCHERE.—The action which was brought by Mr. Cyrus Field against the proprietor and editor of *Truth* for libel, has, fortunately for both parties, terminated amicably. The libel and inuendos were set forth in the plaintiff's statement of claim as follows:—"At a meeting of the company" (meaning the Anglo-American Telegraph Company, Limited), "held last week, Mr. William Abbott moved that Mr. Cyrus Field should not be re-elected. This worthy philanthropist, it would appear, was concerned in the issue of the Wabash Preference Stock, on which shares dividends were paid until the British public had been induced to buy it, when they fell from 92, the issue price, to about 12. According to the American newspapers Cyrus Field has made by the operation about £1,000,000. Under these circumstances Mr. Abbott was right in opposing the re-election of this gentleman." The case was heard before Mr. Justice Denman and a special jury. Sir Henry James, Q.C., and Mr. Pollard were counsel for the plaintiff; and the Attorney-General (Sir Charles Russell, Q.C.), Mr. Crump, Q.C., and Mr. E. Hume Williams appeared for the defendant. Sir Henry James opened his case in an able speech, in which he met the allegations contained in the libellous paragraph with a direct denial. He further pointed out that Mr. Field's only object in bringing the action was to clear himself from the imputations cast on him, and that, the defendant having withdrawn all the imputations, the parties had agreed that a juror should be withdrawn, and the plea of justification struck out. The Attorney-General said that Sir Henry James's case was that Mr. Field had had nothing to do with the transactions in question, but did not deny that such had taken place. On inquiry Mr. Labouchere had found out that Mr. Field's connection with the company had ceased before any of the Wabash Preference Stock was issued. The statement was made on the authority of Mr. Abbott. Sir Henry James then said that Mr. Abbott, when his attention was called to the statements, wrote withdrawing those he made at the meeting of the Anglo-American Telegraph Company. His lordship assented to the course proposed by the learned counsel. A juror was accordingly withdrawn and the case settled.

THE SOCIETY OF TELEGRAPH-ENGINEERS.—The members and friends of this society, invited by its president, Prof. Hughes, F.R.S., and Mrs. Hughes, held a *conversazione* in the rooms of the Royal Institute of Painters in Water Colours, Piccadilly, on Tuesday evening 29th inst. A very large company of ladies and gentlemen were presented, and during the whole three hours, from nine till midnight, the rooms were crowded by a brilliant array of beauty and learning. It is the first time the society's annual gathering has taken place in the rooms of this institute, on whose walls the display of a vast collection of water-coloured drawings of unique interest added greatly to the charm of the scene and the pleasure of the visitors. Among the visitors present were:—Lord Alfred Churchill, Count Victor Wimpffen, Sir James Crichton Brown, F.R.S., Sir James Ramsden, Sir Henry Thompson, F.R.C.S., Sir Henry Mance, C.I.E., Sir Charles Bright, Sir Samuel Canning, Sir Frederick Abel, C.B., F.R.S., Sir James Linton, President R.I.; Admiral Sir Edward Inglefield, C.B., F.R.S.; Captain Sir George Nares, R.N., K.C.B., F.R.S.; Major-General E. R. Festing, R.E., F.R.S.; Major-General C. E. Webber, R.E., C.B.; Major-General J. T. Walker, F.R.S.; Colonels Stotherd, R.E., Sir Francis Bolton, Granville Puget, Harrison, C.B., R.E.; Majors R. Y. Armstrong, R.E., J. G. B. Stopford, G. E. C. Beresford, R.E.; M'Gregor R.E.; Captains H. R. Sankey, R.E., C. A. McEvoy, Douglas Galton, C.B., F.R.S., Ladds, F. R. de Wolski, R.E., H. J. Holden, R.A.; Lieutenant Anstruther, R.E.; Monsieur E. Hospitalier, Gaston Roux; Herr Hogmeister; Profs. G. G. Stokes (President R.S.), J. C. Adams, LL.D., F.R.S., G. T. Bonney, F.R.S., Vernon Harcourt, F.R.S., G. D. Liveing, F.R.S., A. S. Herschell, F.R.S., Roberts-Austen, F.R.S., W. G. Adams, F.R.S., W. E. Ayrton, F.R.S., John Perry, F.R.S., G. C. Foster, F.R.S., A. W. Reinold, F.R.S., J. S. Fleming, M.A., D.S.C., George Forbes, F.R.S.E., Silvanus P. Thompson, F.R.A.S., F. Guthrie, F.R.S., W. N. Stocken, M.A., E. Ray Lankester, LL.D., F.R.S, John Tweedy, A. J. Bernays; Drs. Hugo Müller, F.R.S. (President Chem. Soc.), Benjamin Ward Richardson, F.R.S., E. Frankland, LLD., F.R.S., John Rae, F.R.S, J. H. Gladstone, F.R.S., J. Hopkinson, F.R.S., R. Quain, F.R.S, H. J. P. Sprengel, F.R.S., M. J. Jackson, Meymott Tidy; Messrs. J. M. Swan, W. Crookes, F.R.S., Latimer Clark, Willoughby Smith, C. E. Spagnoletti, W. H. Preece, F.R.S.; E. Greaves, W. T. Ansell, R. E. Crompton, Alexander Siemens, A. Stroh, Lant Carpenter, Gisbert Kapp, John Munro, C. H. B. Patey, J. Farquharson, E. Cowper, Conrad Cooke, C. H. W. Biggs, H. R. Kempe, S. M. McGowen, H. G. Erichsen, J. Wimshurst, Trueman Wood, C. W. Vincent, P. W. Willans, R. von F. Treuenfeld, F. Despointes, D. FitzGerald, H. Clifford, and Daniel Adamson.

TELEPHONIC STATISTICS.—The following is a continuation from our last issue of M. Rothen's telephonic statistics:—

Inter-Urban Communication.

Germany

Berlin–Magdeburg (110).	Hamburg–Bremerhaven.
Berlin–Lubec.	Francfort-s./M.-Mayence.
Berlin–Potsdam (17½).	Hamburg–Lübeck (42).
Berlin–Ludwigsfelde (25).	Brême–Bremerhaven (43).
Berlin–Charlottenburg.	Cologne–Deutz.
Crefeld–Bonn (16).	Barmen–Elberfeld.
Crefeld–Lobberich (16).	Hamburg–Altona.
Düsseldorf–Crefeld–München-Gladbach.	Cologne–Bonn (16).
	Mannheim–Heidelberg (14).
Elberfeld-Barmen-Langenberg.	Dresden–Pirna (12½).
Neuss–Cologne–Bonn.	Mulhouse–Thann (13).
Francfort-s./M.-Mannheim(53).	Mulhouse–Guebwiller (14).

The total length of the inter-town wires already amounts to 1,378 miles.

Sweden.

Stockholm-Rotebro-Upsala-Södertelji-Moulbo-Trosa-Dalarö-Vaxholm.

The gradient of these distances is 50cm.

Switzerland.

1st Group.	4th Group.
Berne-Bienne (19).	St-Gall-Amrisweil (11½).
Berne-Thoune (18½).	St-Gall-Arbon (8).
Berne-Muri (3).	St-Gall-Hérisau (6).
2nd Group.	St-Gall-Rorschach (7½).
Chaux-de-Fonds-Gernier (8½).	St-Gall-Speicher (3).
Gernier-Neuchâtel (8½).	St-Gall-Teufen (2¼).
Neuchâtel-St-Blaise (3).	5th Group.
Chaux-de-Fonds-Locle (1).	Zurich-Adliswyl (2½).
Chaux-de-Fonds-St-Imier (12).	Zurich-Affoltern (11).
3rd Group.	Affoltern-Lucerne (19).
Geneva-Bellevue (4).	Zurich-Baden (14½).
*Geneva-Lausanne (38).	Zurich-Horgen (9).
*Geneva-Nyon (14).	Horgen-Richtersweil (4½).
Geneva-Vandœuvres (3).	Zurich-Thalweil (6¼).
*Lausanne-Morges (8½).	Thalweil-Wädensweil (7).
*Morges-Nyon (15).	Zurich-Uster (11).
Lausanne-Vevey (11).	Uster-Wetzikon (4½).
Vevey-Montreux (4).	Zurich-Winterthur (12½).
Montreux-Aigle (8½).	Winterthur-Schaffhousen (16½
Aigle-Bex (6).	*Zurich-Stäfa (14½).
	Bâle-Liestal (11).

All the exchanges of each group can converse with one another. Except between Geneva and Lausanne and between St. Gall and Hérisau, where two wires are available for telephony, there is only one wire.

The communications marked with an asterisk are established by means of the Van Rysselberghe system.

ALTERNATING AND INDUCED ELECTROMOTIVE FORCES.—I.

BY W. H. SNELL.

The first mathematical investigation on the subject of alternating and induced electromotive forces was, I think, given by Clerk Maxwell in the year 1865 (see *Phil. Trans.* for that year, p. 469). Since that date Mascart and Joubert have treated the question at length in the *Journal de Physique*, and more recently all electricians will remember that both Dr. Hopkinson and Mr. T. Blakesley have added largely to our knowledge of the subject.

So far, however, neither these writers, nor any others with whom I have made acquaintance, have shown any merciful consideration for that numerous and not wholly undeserving class of individuals whose mathematical attainments are of limited extent. There are undoubtedly many electricians who have frequently to deal with alternating currents to whom this important series of investigations remains a sealed book, or who at the best have had to content themselves with getting some idea of the general character of the results. With the advent of secondary generators these questions have become of more immediate importance, and it therefore seems to be desirable that the subject should be presented in as simple a form as its nature will permit. The writer will endeavour to show that it is possible to make considerable progress in the treatment of these problems without resorting to any abstruse mathematics; and, at the same time, it will be his endeavour to keep well in view of the physical as well as the merely mathematical reasons for the results which are obtained.

It will, however, be absolutely necessary that we should wander far afield from the primitive simplicity of the law of Ohm. It is really a remarkable fact that so long as we are dealing with electromotive forces, continuous in direction and constant in value, then no matter how numerous these may be, or how complex the circuit in which they operate, the law of Ohm, together with the corollaries deduced therefrom by Kirchoff, will suffice to determine the electrical conditions in every part of the conducting circuit. But whenever the electromotive force undergoes continual fluctuations, either in numerical value or in direction, the case immediately becomes widely different. Even in the most simple circuit we have now to consider not merely the three terms whose relations were formulated by Ohm, but we must also know the value of the coefficient of self-induction, the periodic time of the alternations, and the shape of the curve which represents the rise and fall of the electromotive force. Furthermore, if there should be any independent conducting circuits in the immediate neighbourhood, we have, in addition, to consider the coefficients of mutual induction with those circuits, and the reaction of their currents upon the current in the primary.

It seems not unlikely that some additional difficulty has been thrown in the way of students who approach this subject for the first time, by certain statements which either expressly assert or else seem distinctly to imply that the law of Ohm no longer holds good at all in the case of alternating currents. For instance, we are told that "the phase of the current lags behind the phase of the electromotive force," or in other words that the current is not at a maximum at the same moment at which the electromotive force is a maximum. Now, if so stated, this is clearly inconsistent with the law which we have been taught to consider in the light of the fundamental principle of dynamic electricity. Nevertheless, it need hardly be said that the statement is perfectly true in the sense in which it is intended by the writers who make use of it. But the electromotive force referred to is not the actual total electromotive force to which the current in the circuit is really due, but only one component part of that total. The statement, in fact, applies solely to the "impressed" electromotive force, that is to the electromotive force which is the original source of the electrical action taking place in the circuit.

Now if any circuit contain an electromotive force whose value changes from moment to moment, then that circuit must *de facto* possess at least one and possibly two or more separate and distinct electromotive forces in addition to that of the original source. It follows, of course, that the current at any moment will be equal to the algebraic sum of these electromotive forces divided by the actual resistance of the circuit. And, for reasons which we shall consider later, it also happens that the maximum value of the current at each alternation is attained somewhat later than that of the impressed electromotive force. But, upon the other hand, the rise and fall of the current is necessarily and absolutely concordant with that of the resultant or total electromotive force.

The problem of determining the periodic values of an alternating current under any given conditions is therefore resolved into that of determining the resultant E.M.F. at each moment. If we can do this, we return forthwith to the simple application of the law of Ohm; dividing the resultant E.M.F. at any moment by the actual resistance of the circuit, we obtain the current at that moment.

For the complete solution, then, of any problem whatever relating to a conducting circuit traversed by alternating currents we require only one additional fundamental principle. That principle is usually stated in the following terms:—Induced electromotive forces are at all times proportional to the rate of decrease in the total number of lines of force passing through the circuit. It may be worth while to remark at this point that the number of lines of force enclosed by a circuit can only decrease by some of the lines passing through, or "cutting," the conductor. This is because a line of force only disappears by retreating into the magnet or the conductor to which it belongs; it cannot vanish in mid air.

Let us now consider a particular case of the generation of an alternating electromotive force; and assume, in the first place, that there is no self-induction in the circuit; that is to say, suppose that none of the lines of force generated by the current in the circuit pass through the conductor at any point. It is well known that under these circumstances the lines of force belonging to the circuit surround the conductor in a series of concentric rings lying in planes perpendicular to the path of the current.

In such a circuit imagine a single loop of wire* placed in a uniform field of magnetic force, and let it be rotated about an axis which passes through the loop as a diameter, in a direction perpendicular to the direction of the lines of force. Then it is obvious that when the plane of the loop is perpendicular to the direction of the lines of force, the number of lines passing through the loop will be a maximum; when it has turned through an angle of 90° the number will be zero, and after turning through 180° the number of lines threading the loop will again be a maximum; but they now enter the loop at the opposite side.

Let the maximum number of lines which can pass through the loop be N. And let θ be the angular position of the coil, measured always in the same direction from 0° to 360°, from the position where the number of lines threaded is a maximum. Then if N_1 be the number of lines for any given valve of θ, we shall always have

$$N_1 = N \cos \theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and as θ has all values from 0° to 360°, cos θ will have all values from + 1 to − 1.

Now, let E_1 be the impressed electromotive force generated in the coil at any point during the revolution. Then we know that E_1 is proportionate to the rate of decrease of the values of N_1. It therefore depends not only upon N_1, but also upon the rapidity of the rotation of the coil. Let t be some very short interval of time, then the rate at which N_1 changes during that short interval will be measured by taking the first differential coefficient of N_1 with regard to t. That is

$$E_1 = -\frac{d N_1}{d t}.$$

Substituting the value of N_1 from (1) we have

$$E_1 = -\frac{d N \cos \theta}{d t} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Now, if the time occupied in a whole revolution—that is in describing an angle of 2π radians—be T, it is obvious that the

* Of course, there would actually be a certain amount of self-induction even in a single loop.

Digitized by Google

angle θ, which is described during the short time t will be given in radians by

$$\theta = 2\pi \frac{t}{T} \quad \ldots\ldots\ldots \quad (3)$$

Inserting this value of θ in (2) and performing the differentiation, we obtain

$$E_1 = \frac{2\pi N}{T} \sin \frac{2\pi t}{T} \quad \ldots\ldots \quad (4)$$

It will be understood that in this equation t must be given succcessively all values from 0 up to T.

The successive values of E_1 during one complete revolution may therefore be represented by the ordinates of a sinusoidal curve, and the greatest ordinate will be equal to $\frac{2\pi N}{T}$. It may be as well to note here that the rise and fall of an alternating current is not necessarily represented by a curve of sines. Theoretically the alternations might be made to take place according to some quite different law.

Let us now introduce into the circuit a coefficient of self-induction; this is usually denoted by L. And, in the first place, it must be remembered that coefficients of self (and also mutual) induction properly belong to the circuit *as a whole*, so that if the value of L be the same it is a matter of indifference whether the self-induction takes place in the armature of the dynamo or in any other part or parts of the circuit. Now, there are four separate and distinct terms belonging to self-induction which it is important to carefully distinguish. These are (1) the coefficient of self-induction; (2), the total self-induction; (3), the electromotive force of self-induction; (4), the current of self-induction. And their definitions are as follows:—(1), the coefficient of self-induction is a concrete quantity representing the numbers of its own lines of force which would be enclosed by the circuit if it were traversed by a unit current; (2), the total self-induction of a circuit at any time is measured by the product L I, where I is the current at the moment; (3), the electromotive force of self-induction depends, like other induced electromotive forces, upon the rate of change in the number of the lines of force to which is due. It must therefore be measured by

$$E_2 = -\frac{d\,L\,I}{dt} \quad \ldots\ldots\ldots \quad (5)$$

[4.] Finally, the current of self-induction is, of course, equal to E_2 divided by the total actual resistance of the circuit.

There are several points in connection with these definitions which it will be well to notice before we proceed. Strictly speaking the coefficient of self-induction depends solely upon the geometry of the circuit. It has a minimum value when the conductor takes the form of a single wide loop, but in a circuit of the same length and resistance, part of which is coiled up, the value of L increases very nearly in proportion to the square of the number of turns in the coil. But if L be taken as a function of the geometry of the circuit alone, then the *total* self-induction of the circuit will depend not only upon L and upon I, but also upon the magnetic permeability of the space adjacent to the circuit. And if this space contain iron the self-induction will be very greatly increased. Theoretically we ought, therefore, to express the total self-induction as a function of the strength of the current multiplied into the sum of two terms, of which the second would be a somewhat complex expression—it would contain a saturation term, and also the coefficient of magnetic permeability, which latter varies for every different kind of iron. In practice it is, therefore, much more simple to take L as representing the whole number of lines of force embraced by the circuit, and due immediately to the current in the circuit, whether they belong to the conductor or whether they belong to adjacent masses of iron. This convention will not require any alteration in our definition of L, but the total self-induction will now only be proportionate to L I so long as we are working at some distance from the saturation point of the iron. Practically, in induction circuits it may be safely assumed that this will be the most general case. Another point that may be noted in connection with L, is that this number bears no necessary relation whatever to the number of lines in the magnetic field in which the current is generated. This will be sufficiently obvious if we consider that L may be increased indefinitely by continuously increasing the length of the conductor. And if its diameter be increased at the same time in such a manner as to maintain its resistance constant, then the *total* self-induction will also increase indefinitely.

Now, let E be the total or resultant E.M.F. in the circuit, so that E is equal to the sum of the values of E_1 and E_2 taken with their proper signs. That is from (4) and (5)

$$E = \frac{2\pi N}{T} \sin \frac{2\pi t}{T} - L\frac{d\,I}{d\,t} \quad \ldots\ldots \quad (6)$$

Now, in this equation we cannot directly perform the differentiation indicated in the last term, because we do not at present know the value of I nor its relation to t. But we may proceed to solve the equation by means of a series of successive approximations (without treating it as a differential equation) in the following way:—Divide both sides by R, the total resistance of the circuit, thus

$$\frac{E}{R} = I = \frac{2\pi N}{RT} \sin \frac{2\pi t}{T} - \frac{L}{R}\frac{d\,I}{d\,t} \quad \ldots \quad (7)$$

Now, as a first approximation to the value of I we may neglect the term containing L and put

$$I_1 = \frac{2\pi N}{RT} \sin \frac{2\pi t}{T} \quad \ldots\ldots \quad (8)$$

Substitute I_1 for I in the second term of (7), then as a second approximation we have

$$I_2 = \frac{2\pi N}{RT}\left(\sin\frac{2\pi t}{T} - \frac{L}{R}\frac{d}{dt}\sin\frac{2\pi t}{T}\right)$$

$$= \frac{2\pi N}{RT}\left(\sin\frac{2\pi t}{T} - \frac{L}{R}\frac{2\pi}{T}\cos\frac{2\pi t}{T}\right)$$

We may now replace I by I_2 on the right hand side of (7), and so obtain a third approximation. If we proceed in this way the following are the values of the successive approximations for the first four terms after I_1. For the sake of brevity we will put θ for $\frac{2\pi t}{T}$ as before, and we will also write a for the expression $\frac{L}{R}\frac{2\pi}{T}$.

$$I_2 = \frac{2\pi N}{RT}(\sin\theta - a\cos\theta) \quad \ldots\ldots\ldots \quad (8a).$$

$$I_3 = \frac{2\pi N}{RT}(\sin\theta - a\cos\theta - a^2\sin\theta) \quad \ldots\ldots \quad (8b).$$

$$I_4 = \frac{2\pi N}{RT}(\sin\theta - a\cos\theta - a^2\sin\theta + a^3\cos\theta) \quad \ldots \quad (8c)$$

$$I_5 = \frac{2\pi N}{RT}(\sin\theta - a\cos\theta - a^2\sin\theta + a^3\cos\theta + a^4\sin\theta) \quad (8d)$$

We have written down these four terms in full in order that the law of their formation may easily be seen by inspection, especially with regard to the signs of the successive terms.

It will now be clear that the value of I may be expressed as the sum of an infinite number of terms of this series, multiplied into the factor $\frac{2\pi N}{RT}$. But the series may be written in the form $\sin\theta(1 - a^2 + a^4 - \ldots) - \cos\theta(a - a^3 + a^5 - \ldots)$; that is, $(1 - a^2 + a^4 - \ldots)(\sin\theta - a\cos\theta)$.

And the sum to infinity of this geometrical progression is equal to $\frac{1}{1+a^2}$

So that finally

$$I = \frac{2\pi N}{RT} \cdot \frac{(\sin\theta - a\cos\theta)}{(1+a^2)} \quad \ldots\ldots \quad (9)$$

or in full

$$I = \frac{2\pi N}{RT} \cdot \frac{\left(\sin\theta - \frac{2\pi L}{RT}\cos\theta\right)}{\left\{1 + \left(\frac{2\pi L}{RT}\right)^2\right\}} \quad \ldots \quad (9a)$$

Digitized by Google

The value of I may, however, be obtained in a more convenient form by making the following trigonometrical transformation. First let ϕ be an angle whose tangent is equal to a, that is let

$$\phi = \tan^{-1} a.$$

Then

$$\frac{\sin\theta - a\cos\theta}{\sqrt{1+a^2}} = \frac{\sin\theta - \cos\theta\tan\phi}{\sqrt{1+\tan^2\phi}}$$
$$= \sin\theta\cos\phi - \cos\theta\sin\phi$$
$$= \sin(\theta - \phi)$$

Making this substitution in (9) we get

$$I = \frac{2\pi N}{RT} \cdot \frac{\sin(\theta-\phi)}{\sqrt{1+a^2}}$$

or

$$I = \frac{2\pi N}{T} \cdot \frac{\sin(\theta-\phi)}{\sqrt{\left(\frac{2\pi L}{T}\right)^2 + R^2}} \quad . \quad (10)$$

Now, if there were no self-induction in the circuit I would have the value I_1 in (8). It, therefore, appears that self-induction has the effect of reducing the mean value of the current in the proportion

$$\frac{R}{\sqrt{\left(\frac{2\pi L}{T}\right)^2 + R^2}}$$

and at the same time the rise and fall of the current is evidently retarded. The impressed E.M.F. will be at a maximum when $\theta = 90°$; that is, when the plane of the coil is parallel with the lines of force of the magnetic field, and the number of lines passing through the coil is for the moment zero. But the resultant current attains its maximum at the moment when $\sin(\theta - \phi) = 1$, that is when $(\theta - \phi) = 90°$. In the next paper we shall give a diagram from which the physical cause of the retardation of the current may very readily be inferred. All that we have done at present is to ascertain its existence as a mathematical fact. In the meantime, we may note that the angle ϕ remains constant (through all the changes of θ) so long as the resistance of the circuit, its coefficient of self-induction, and the speed of rotation are unchanged.

PRACTICAL ELECTRICITY FOR AMATEURS.—IV.* Electric Bells and Indicators.—*(Continued.)*

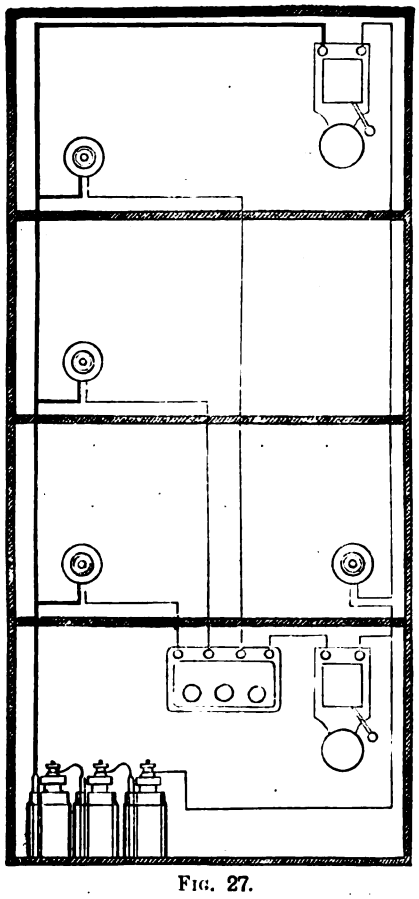

Fig. 27.

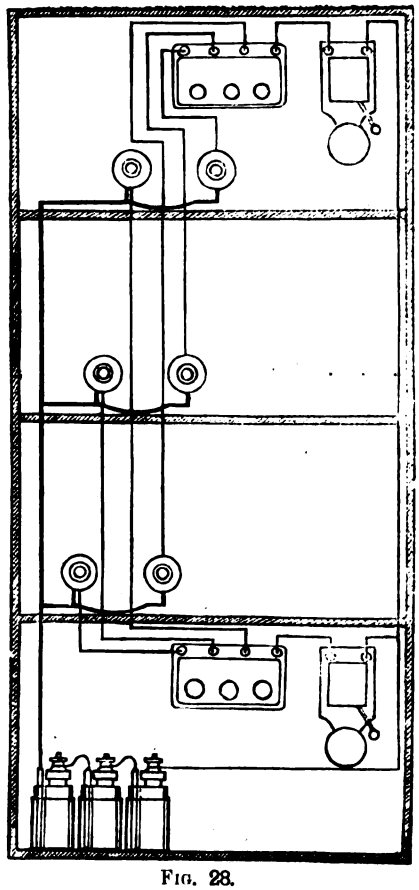

Fig. 28.

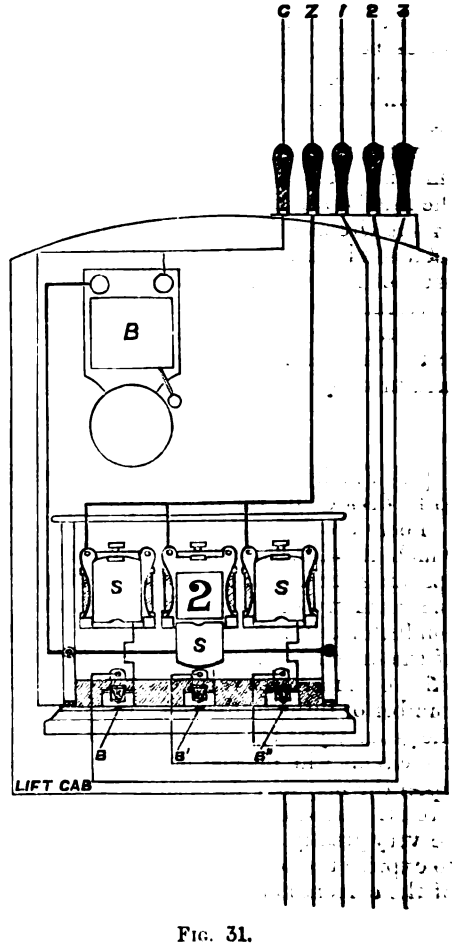

Fig. 31.

Fig. 27 shows the most simple arrangement of electric bells and indicators, having three rooms to ring downstairs, and one push in hall to ring at top of house.

Fig. 28 shows arrangement having two pushes in each room, one to ring upstairs and the other downstairs.

Fig. 29 shows an arrangement such as would be used in a hotel or large establishment. The indicator placed on each floor shows the particular room, the indicator on ground floor merely indicates the floor. This arrangement saves carrying all the wires to the ground floor, and is more convenient in many respects.

Figs. 30, 31, and 32 show an arrangement of electric bells and indicators applied to a lift enabling any person from any floor to ring a bell and indicate the floor in the lift cab, and to receive a ring in reply, and this can be done in whatever position the lift cab may be in. Fig. 30 shows the bare wires, C, Z, 1, 2, 3, running from top to bottom of lift well, and kept tight by weights placed at the bottom, also the connections on each landing. The connections with the cab are maintained by the rubbing contacts C, C', and are shown in Fig. 31, which also shows the connections in cab.

Fig. 32 shows how the contacts C, C', &c., act against the bare wires before named.

THE BASSANO TELEPHONE APPEAL.

There is a sign of returning common sense amid the amusing and ludicrous pronouncements that are delivered by eminent and learned lawyers who sit in judgment on scientific patent cases. The decision of the Court of Appeal given on Monday last in the case of the UNITED TELEPHONE COMPANY *versus* BASSANO, though it nominally upholds the decision of Mr. Justice NORTH, does not altogether endorse the peculiar logic and the travesty of science which distinguished the judgment in the earlier case. We commented in our issue of April 2nd, upon the amazing features of that judgment and the comical farce enacted by the eminent experts who were retained to give evidence in the case. They deluded the Court into declaring that a conical tube of wood open at both ends was a "diaphragm," because it was thin enough to vibrate when someone talked into it. They succeeded in establishing the notion that EDISON had called carbon a semi-conductor, when the fact was that in his specification the well-known substance, carbon, was never once mentioned; and, more amazing still, they worked upon the imagination with such exaggerated accounts of EDISON'S merits that finally EDISON, not GRAHAM BELL nor REIS, was declared the true inventor of the first electric speaking telephone, and was therefore entitled to have the language of his specification construed in the widest possible sense.

Quite apart from any question as to this mischievous doctrine of "benevolent construction," quite apart, too, from the fact that the questionable practice of giving to an inventor more than the plain wording of his claims entitle him to is exercised by judges in those cases only where the suit is brought by a wealthy firm or corporation, the unreasonableness of this judgment was so apparent that at one time the "North diaphragm," as contrasted with a real diaphragm, seemed destined to pass into the current language of electricians. The Appeal Court has certainly been a little less unscientific, a little more strict in its logic. The Court was invited, on the one hand, by the counsel for the defence to decide whether Mr. BASSANO would still be infringing the Edison patent by using the open wooden tube without the backboard of mahogany which closed diaphragm-wise its lower end. It was exhorted, on the other hand, by the counsel for the plaintiffs to declare, with Mr. Justice NORTH, that a thin tube, because it can vibrate as a thin diaphragm does, is a diaphragm. In the sequel the Court, by the mouth of Lord Justice COTTON and Lord Justice LINDLEY, declined to follow where Mr. Justice NORTH had rushed in, and refused to make any answer on the point, declaring that it was not the duty of the Court to point out the exact particular of the construction to which the infringement was due, and added that the question would be discussed when it arose.

We venture to think that on this point the Lords Justices of Appeal might have been more explicit. The point had actually arisen in the Court below; it had been treated as a distinct issue by Mr. Justice NORTH. Some of the actual instruments brought into court as infringements possessed no backboard. A grievous injustice has, as it seems to us, been inflicted on Mr. BASSANO by the refusal of the Court to entertain and decide this simple issue. It is perfectly plain to every unbiased mind that when EDISON said diaphragm he meant diaphragm, and did not mean tube. The refusal of the Appeal Judges to hear and decide this simple issue is much to be regretted, as it is giving countenance to a growing impression that in cases of this kind the Court must always lean to the side of the man in possession. Why cannot our judges pluck up a little more independence, and say plainly that a tube is not a diaphragm when the question is put before them? Suppose it possible for a learned judge to give a decision, based upon expert evidence, that black was red, and that the case were taken to the Appeal Court with a formal request that the issue should be heard and decided whether black was red. What would be thought of the Judges of Appeal who should reply that they would discuss the question when it arose?

Still more to be deplored is that part of Lord Justice COTTON'S decision which relates to the carbon question. It is notorious that EDISON never named carbon, or anything approaching a pencil microphone, until after HUGHES'S classical researches. It is equally notorious that on the strength of a decision snatched in a Scotch Court against a bankrupt defendant the advocates of the telephone monopoly have continued to instil into the English Courts the notion that EDISON in some way is entitled to claim HUGHES'S microphone. Lord Justice COTTON delivers himself thus on the matter:—"Edison had mentioned several sorts of tension regulators, but in that which had ultimately been preferred there *were fixed blocks and suspended pencils of carbon.*" We italicise the words from a report in *The Times*. Anything more strangely inaccurate can hardly be imagined. Every one conversant with the subject knows that these words are not found in EDISON'S specification, and do not describe

Digitized by Google

anything to be found therein, but describe HUGHES'S microphone. The judge goes on to say: "Substantially *the same thing* was used in the defendants' instrument, *though the carbons were fixed to the base of the speaking tube* instead of being situated, as in EDISON'S instrument, on the other side of the diaphragm. *In his Lordship's opinion the defendants' instrument was an infringement of Edison's patent.*" It is difficult to conceive a more unscientific mode of argument. First import into EDISON'S specification something that was not there to begin with, but which was the subsequent invention of Hughes; then discover that the defendants' instrument is so much like it as to be practically the same; then declare it to be an infringement! This is virtually what the united wisdom of bench, bar, and professional experts has succeeded in doing.

CORRESPONDENCE.

THE THOMSON-HOUSTON SYSTEM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We notice in to-day's paper that you mention the City of Hernosand, Sweden, as being the first city in Europe where electricity has entirely superseded gas for public lighting, and as you have mentioned the fact, we think it right that you should also name the system adopted, which is the Thomson-Houston. This installation was the first result of the gold medal awarded to us at the Inventions Exhibition last year, and the plant has been running with the utmost satisfaction to everybody concerned since November last.—Yours, &c.

LAING, WHARTON, AND DOWN.

London, E.C., June 26th, 1886.

THE UPWARD PRIMARY BATTERY.

For a long time past great efforts have been made to induce the general public to believe in primary batteries for electric lighting purposes. The most glowing accounts as to cost, cleanliness, non-supervision, and other properties, appealing to the public have been freely circulated. It needs a strong mind and most careful analysis to cast aside the glamour of

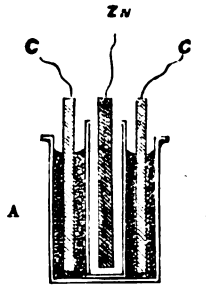

FIG. 1.

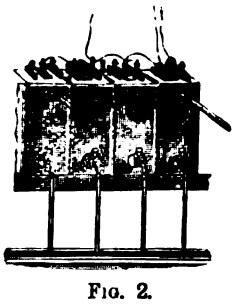

FIG. 2.

the descriptions given by patentees and manufacturers, and to show that so far, there is in existence no single battery that is anything but a luxury for electric lighting purposes. The public is imposed upon by half truths. Primary batteries are not such simple things as many imagine. It is needless, however, to enter into a long discussion upon these points at present. Let us accept for the moment that such apparatus is intended for those only who can afford to pay for luxuries, and our way is made clear. Under these conditions the battery invented by Mr. Upward, and made by Messrs. Woodhouse and Rawson, is a success. Viewed scientifically it possesses many interesting features. It is at once a gas battery and a single fluid battery. Our readers will better understand the battery from the section in Fig. 1, and the cells as in use in Fig. 2. In Fig. 2 the vertical glass tubes are the drainage tubes.

A is a glazed earthen vessel containing a porous jar. Inside the porous jar is placed a slab of zinc. Carbon plates CC are placed on each side the porous jar, and surrounded by granular crushed carbon packed and pressed closely together. The top of the carbon compartment of the cell is hermetically sealed by a material of the nature of marine glue—hence, no gas let into the carbon can escape except through the porous jar. The zinc plate in this jar is surrounded by a solution of chloride of zinc. When the cell is required for use gaseous chlorine enters, or rather is drawn into, the cell by a very interesting arrangement. A lead pipe goes from the top of one cell to the bottom of the next, and the gas passes from cell to cell through these pipes. Messrs. Woodhouse and Rawson have favoured us with a copy of Prof. Lodge's report upon this battery, and to this report we are largely indebted in this article. Dr. Lodge says, "The elements of the battery are zinc immersed in a solution of chloride of zinc contained in a porous vessel, on the one hand; and crushed carbon immersed in gaseous chlorine and kept moist by the deliquescent action of the zinc-chloride which oozes through the porous pot into the outer vessel, on the other. The outer vessel is allowed constantly to drain so as to never contain any loose liquid; it is only intended to contain as much as will keep the carbon properly moist. When the circuit is closed zinc dissolves and chlorine is taken up in precisely equivalent proportions, and when the circuit is open no chemical action occurs, the zinc being entirely unattacked, and all chemical action being in abeyance except when a current passes. The solution in the inner vessel tends to become stronger as the battery is worked, the chloride of zinc needed being generated by the battery's own action; so if loss of fluid be made up by addition of plain water it is possible to keep the solution at a reasonably constant strength. The deliquescent property of zinc-chloride prevents any difficulty with crystallisation and creeping. If the battery is in regular work it should give little or no trouble, and even if it stand idle for long the only change is that the liquid in the porous cells either falls in level or else becomes more dilute. . . . No mixing of solutions can occur, as there is only the one liquid and there is no electrical waste on standing, for as soon as the supply of chlorine is exhausted the battery stops working. The E.M.F. of the battery is from 2 to 2·1 volts, and it is extremely constant so long as a free supply of chlorine is maintained."

It will be seen that the active ingredient is chlorine gas. This gas is by no means a harmless gas to handle, and precautions have to be taken for its manufacture and storage. In the experimental installation at the works of Messrs. Woodhouse and Rawson it is obtained from common salt. A glazed earthenware jar, or retort, of the size required, is placed in a sand bath. The retort is charged with the materials used, and a gentle heat applied. The gas is given off and stored in an ingenious gasometer, consisting of glazed drain pipes placed on end and hermetically sealed at the junctions. From tier to tier of pipes is a leaden tube carrying a glass bulb. This bulb being placed near the top of the tier enables the workmen to see when the gasometer is full. The gas can be drawn from the store as required. "From the holder the gas passes through lead pipes to the series of cells into which it is drawn by their own action in a constant stream while they are working. At intervals, however, a supply is needed for a short time greater than what the mere absorbing power of the carbon can provide. Whenever this happens a very beautiful automatic arrangement turns on a small water aspirator, and sucks in the necessary extra gas. This part of the apparatus may be taken as almost perfect or likely at once to become so. The obvious question of smell suggests itself, but it will be found that the battery and the gas holder are so well sealed up that from them there is practically no smell at all. Any slight excess of unconsumed chlorine which the water aspirator may suck through (and it is very slight, for the aspirator only acts for a minute or so at a time, and rests for an hour or more) is at once carried down into the drains, where it must do the reverse of harm. The internal resistance of a cell as now constructed is rather high, being about a quarter or a fifth of an ohm. This is a distinct disadvantage, as it renders the battery non-self-regu-

Digitized by Google

lating when working by itself, but the patentees have evaded this objection by combining with it a secondary or storage battery of about half the number of cells; these constitute the real source whence the external circuit is worked, and, of course, they are perfectly self-regulating, so that whether one lamp or thirty are lighted the change need make no difference to the potentials of the terminals, and therefore to the brilliancy of the lights. The function of the primary battery is thus simply to keep the storage battery always full. . . . The primary and secondary batteries are never in practice disconnected. So soon as the secondary is full the primary slackens and chlorine is drawn into it less quickly. Directly the secondary is drawn upon, the primary at once begins to make up the deficiency and its activity varies with the demand made upon it. No back current can ever be formed, and the constant filling and occasional overfilling of the accumulators is exactly the condition under which they are known to work best and last longest. Accumulators so charged are, in fact, in quite the most favourable circumstances, and may be expected to give no trouble. The virtual power of the primary is of course by this arrangement enhanced, since it may take all day to replenish the loss of a few hardworking hours, so that a battery of given dimensions and prime cost is enabled to run a larger number of lamps than if it were only working during lighting hours. Moreover, the use of accumulators enables the battery to work often at more moderate activity instead of always straining at its maximum output.

"When the battery is properly and finally set up it may be trusted to work quite regularly and without attention day and night so long as the chlorine is made when required, and so long as fresh water is added both to the primary and the secondary cells. This last operation, the addition of water, is a very simple one, and it may perhaps be made automatic, in which case there will be nothing to see to but the manufacture of chlorine whenever the store in the gasholder gets low." Dr. Lodge says that "the main first cost of an installation consists of the cells, of which two primary and one secondary are needed, for every couple of volts demanded in the circuit. The working cost is made up of zinc, chlorine, and attendance. The last item may be treated as negligible in any house where a boy or man is already kept. 1·2 gramme of zinc are dissolved in each cell per ampere-hour. When the battery is working at full power this means 1,200 grammes of zinc per 1,000 watt hours; when it is gently maintaining the charge of a full accumulator it means little more than 900 grammes of zinc per 1,000 watt hours. But, inasmuch as something is lost in storage we can hardly reckon less than 1½ kilogrammes or 3·3lb. of zinc consumed altogether per 1,000 watt hours actually used."

With regard to the cost of chlorine, it must differ according to the method by which it is prepared, and also according to the quantities required. Dr. Lodge agrees that certain claims made by the patentees as to the advantages of this battery over others in the market are not claimed unjustly. We are entirely in accord with him on this point. They are—

"1. So long as the battery is in regular work, and provided the porosity of the cells has been properly adjusted to begin with, nothing but plain water has to be added occasionally to the battery and no emptying and filling of cells with acid or corrosive liquid of any kind is required.

"2. The plates are never touched or moved from the batteries from the time the zincs are put in till they are consumed, which may be about once a month of usual electric lighting work.

"3. When the battery is at work the zincs are consumed uniformly down to a thin wafer, thus using the whole plate without waste, and enabling all the plates to be renewed on the same day. This equable wear of the plates is an important point, and it is not a matter of accident. It is due to the fact that the same current passes through every cell and to the absence of local or irregular action.

"4. The carbonplates are once for all sealed into their places and never removed.

"5. There is no creeping, and consequently the terminals do not corrode.

"6. There is no polarisation, and the E.M.F. is constant.

"7. There is no local action, and when idle the zincs are not at all corroded. They may stand in the solution unaffected for any length of time. The consumption of materials is simply proportional to the current drawn off, and ceases altogether when the circuit is open.

"8. No removing of the plates for amalgamation is necessary, nor is there any expense or trouble with mercury, ordinary commercial zinc cast in plates without any amalgamation being used.

"9. No washing of porous pots or other parts of the battery is required.

"10. The battery is mainly self-acting; all that is wanted is to supply the cells occasionally with water, and to make the chlorine, a process which by special design of generator is rendered simple.

"11. The light is available at any time of day or night, and it is perfectly steady.

"12. The high E.M.F. of 2·1 volts is that due to the direct action of chlorine upon zinc, and no third substance or 'depolariser' is used at all.

"13. The battery is of a permanent nature. The whole primary battery apparatus may be left standing for months without depreciation, and can be started by filling up the pots and admitting the gas.

"14. There is no smell, dirt, or fume from the cells or from the gasholder.

"15. The arrangements for storing the chlorine, and for its automatic supply to the cells as required, are exceedingly satisfactory and ingenious."

We shall have to return to this subject.

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 139.)

The equations we have arrived at for the dielectric currents seem inconsistent with Helmholtz's definition of them; for since

$$x = \epsilon X,$$

with similar equations for y and z, and since in a medium at rest

$$X = -\frac{dU}{dt} - \frac{d\phi}{dx}, \quad Y = -\frac{dV}{dt} - \frac{d\phi}{dy}, \quad Z = -\frac{dW}{dt} - \frac{d\phi}{dz},$$

where U, V, W are the components of the vector potential. If we consider a surface separating two portions of the same dielectric and coated with electricity whose surface-density is σ, we have, since U, V, W are not discontinuous on crossing the surface,

$$l(\dot{x}_1 - \dot{x}_2) + m(\dot{y}_1 - \dot{y}_2) + n(\dot{z}_1 - \dot{z}_2) = -\epsilon \frac{d}{dt}\left[l\frac{d\phi}{dx} + m\frac{d\phi}{dy} + n\frac{d\phi}{dz}\right]_1^2,$$

where $\left[l\frac{d\phi}{dx} + m\frac{d\phi}{dy} + n\frac{d\phi}{dz}\right]_1^2$ denotes the difference between the values of $l\frac{d\phi}{dx} + m\frac{d\phi}{dy} + n\frac{d\phi}{dz}$ on the two sides of the surface.

But $$\left[l\frac{d\phi}{dx} + m\frac{d\phi}{dy} + n\frac{d\phi}{dz}\right]_1^2 = -\frac{1}{1+4\pi\epsilon}\sigma,$$

so that $$l(\dot{x}_1 - \dot{x}_2) + m(\dot{y}_1 - \dot{y}_2) + n(\dot{z}_1 - \dot{z}_2) = \frac{\epsilon}{1+4\pi\epsilon}\frac{d}{dt}\sigma,$$

and so cannot vanish if the surface-density of the electricity changes; thus Helmholtz's equation seems to be inconsistent with the principle that the change in the quantity of free electricity is caused by conduction currents. In the case above considered, Maxwell's equations lead to no difficulty; it does not follow, however, that Maxwell's assumption that the total current behaves like the flow of an incompressible fluid is absolutely necessary. We shall consider later on the differences which the abandonment of this assumption will make in the theory.

Digitized by Google

We shall now go on to consider Helmholtz's equations and compare them with the corresponding ones in Maxwell's theory.

The quantities U, V, W are given by equation of the form

$$U = \tfrac{1}{2}(1-k)\frac{d\psi}{dx} + \iiint \frac{u}{r}\,d\xi\,d\eta\,d\zeta,$$

where k is the constant which we mentioned before as occurring in Helmholtz's theory, and

$$\psi = -\frac{1}{2\pi}\iiint \frac{d\phi}{dt}\frac{1}{r}\,d\xi\,d\eta\,d\zeta,$$

where ϕ is the electrostatic potential; it follows from these equations that

$$\frac{dU}{dx} + \frac{dV}{dy} + \frac{dW}{dz} = -k\frac{d\phi}{dt}.$$

The corresponding equation in Maxwell's theory is

$$\frac{dU}{dx} + \frac{dV}{dy} + \frac{dW}{dz} = 0,$$

so that these equations coincide if $k=0$. On Helmholtz's theory, this quantity would also vanish, whatever be the value of k, if the *total* current behaved like the flow of an incompressible fluid.

If α, β, γ are the components of the magnetic force, then, on Helmholtz's theory,

$$\frac{d\gamma}{dy} - \frac{d\beta}{dz} = A\left\{\frac{d^2\phi}{dt\,dx} - 4\pi u\right\},$$
$$\frac{d\alpha}{dz} - \frac{d\gamma}{dx} = A\left\{\frac{d^2\phi}{dt\,dy} - 4\pi v\right\},$$
$$\frac{d\beta}{dx} - \frac{d\alpha}{dy} = A\left\{\frac{d^2\phi}{dt\,dz} - 4\pi w\right\},$$

where A is a quantity depending on the unit of current adopted, and is such that the force between two parallel elements of currents at right angles to the line joining them is

$$\tfrac{1}{2}\frac{A^2}{r^2}\,ij\,ds\,ds',$$

where r is the distance between the elements, ij the current through them, and ds ds' their lengths; the corresponding equations on Maxwell's theory are

$$\frac{d\gamma}{dy} - \frac{d\beta}{dz} = 4\pi u,$$

with similar equations for v and w.

If λ, μ, ν are the intensities of magnetisation, θ the coefficient of induced magnetisation, the equations satisfied by the components of the dielectric and magnetic polarisation are of the type

$$\nabla^2 x = \frac{4\pi\epsilon(1+4\pi\theta)}{(1+4\pi\epsilon_0)(1+4\pi\theta_0)}A^2\frac{d^2x}{dt^2} + \left\{1 - \frac{(1+4\pi\theta)(1+4\pi\epsilon)}{k}\right\}\frac{d}{dx}\left\{\frac{dx}{dx} + \frac{dy}{dy} + \frac{dz}{dz}\right\},$$

$$\nabla^2\lambda = \frac{4\pi\epsilon(1+4\pi\theta)}{(1+4\pi\epsilon_0)(1+4\pi\theta_0)}A^2\frac{d^2\lambda}{dt^2},$$

where ϵ_0 and θ_0 are the values of ϵ and θ for air.

These equations show that the dielectric and magnetic polarisations are propagated by waves. For the dielectric polarisation longitudinal waves are propagated with the velocity

$$\frac{1}{A}\left\{\frac{(1+4\pi\epsilon)}{4\pi\epsilon k}\frac{(1+4\pi\epsilon_0)}{(1+4\pi\theta_0)}\right\}^{\frac{1}{2}}.$$

Transverse waves are propagated with the velocity

$$\frac{1}{A}\sqrt{\frac{(1+4\pi\epsilon_0)}{4\pi\epsilon}\frac{(1+4\pi\theta_0)}{(1+4\pi\theta)}}.$$

Longitudinal waves of magnetic disturbances are propagated with an infinite velocity, and transverse ones with the same velocity as the transverse waves of dielectric polarisation. The electrostatic potential is propagated with the velocity $1/A\sqrt{k}$. In Maxwell's theory the corresponding equations are

$$\nabla^2 x = \mu K\frac{d^2x}{dt^2}, \qquad \nabla^2\lambda = \mu K\frac{d^2\lambda}{dt^2},$$

where μ is the magnetic permeability and K the specific inductive capacity, so that for both dielectric and magnetic polarisation the velocity of the longitudinal wave is infinite, while the velocity of the transverse wave is $1/\sqrt{\mu K}$. The velocity of propagation of the electrostatic potential is infinite. If in Helmholtz's theory we put $k=0$, $\theta_0=0$, $\epsilon/\epsilon_0 = K$, while both ϵ and ϵ_0 are infinite, we see that the results of his theory will in this respect agree with Maxwell's.

Though in Maxwell's theory the velocity of propagation of the electrostatic potential is infinite, and in Helmholtz's theory $1/A\sqrt{k}$, the electromotive force at a point, and consequently the dielectric polarisation, does not travel with an infinite velocity in Maxwell's theory, or with the velocity $1/A\sqrt{k}$ in Helmholtz's. We can see the reason of this more easily from Maxwell's theory, as the equations are simpler.

Using the notation of that theory, viz., f, g, h, for the components of the electric displacement, F, G, H for the components of the vector potential, and ϕ for the electrostatic potential, then in a dielectric the equations are

$$\frac{4\pi}{K}f = -\frac{dF}{dt} - \frac{d\phi}{dx}$$
$$\frac{4\pi}{K}\frac{df}{dt} = -\frac{d^2F}{dt^2} - \frac{d^2\phi}{dx\,dt};$$

but since $$4\pi\mu\frac{df}{dt} = -\nabla^2 F,$$

we see that $$\frac{1}{\mu K}\nabla^2 F = \frac{d^2F}{dt^2} + \frac{d^2\phi}{dx\,dt}.$$

Now, since $\nabla^2\phi = 0$, a particular solution of this differential equation will be

$$\frac{dF}{dt} + \frac{d\phi}{dx} = 0,$$

while the general solution will be the sum of this solution and the general solution of

$$\frac{1}{\mu K}\nabla^2 F = \frac{d^2F}{dt^2}.$$

(To be continued.)

WEST AFRICAN CABLES.

We learn that on July 1st the India Rubber, Gutta Percha, and Telegraph Works Company handed over to the African Direct Telegraph Company the cables between St. Vincent and S. Thiago, and between the latter place and Bathurst; these sections having been laid by the Silvertown Company, whose ships, the "Dacia" and the "Buccaneer," have, as previously announced, also completed the cables between Senegal and Bathurst, and Bathurst and Bolama.

The West African Telegraph Company has received information that their cable has been completed between Konakri and Sierra Leone by the Silvertown Company's ships, and as the Telegraph Construction and Maintenance Company have two ships in the same locality we may expect from day to day to hear of the completion of the African Direct Telegraph Company's cable between Bathurst and Sierra Leone, thus giving duplicate communication with Europe to the latter place. The rate agreed to by the West African Telegraph Company and the African Direct Telegraph Company for messages to Sierra Leone, either *viâ* Cadiz or *viâ* St. Vincent, is 6s. 9d. per word.

The "Dacia," having completed her portion of the work, is now on her way home, and the "Buccaneer" is now laying the shore ends at Grand Bassam, Accra, and Porto Novo for the West African Telegraph Company's cables.

The "Silvertown" sails on Saturday with the deep sea part of these sections, and with sufficient cable to continue the West African Telegraph Company's system from Porto Novo on to S. Thomé, Principe, Gaboon, and S. Paulo de Loanda.

ORIGIN OF THE ELECTRIC DISCHARGES OF THUNDER CLOUDS.

M. D. Colladon, in a paper to the *Academie des Sciences*, says it is a well known fact that electric potential constantly increases as we ascend from the earth, and we suppose that a positive electrification reigns in the upper regions of the atmosphere.

M. Palmieri attributes the abundant production of electricity in the storm clouds to the condensation which draws the aqueous particles into drops of rain, and he thence concludes that every cloud which resolves itself into rain is a continual source of electricity.

Now experience shows that the condensation of water does not produce a notable amount of electricity, whilst it is a fact generally demonstrated at all seasons that the layers of air above the clouds are positively electrified in respect to the earth.

M. Faye thinks that the origin of the permanent electrification of the thunder clouds is caused by a continual descent of the layers of air above these clouds; but he seems to attribute the descent always and only to the gyratory and translatory movements which are, he says, always taking place during storms.

The author does not agree with this latter point. He says that the continual observations of electric storms, which he has carried out for 60 years, as well as those given by many other observers of stationary electric storms, accompanied by hail, oblige him to admit that, as well as the great storms engendered by gyratory motion of the atmosphere, and passing rapidly from one place to another, there are others just as numerous, perhaps more so, where the storm cloud remains long stationary, and where the descent of the upper layers of air is essentially due to a shower of rain, apparently the sole cause of the incessant renovation of the electricity of the clouds and sometimes also of the freezing of their drops of rain into hailstones.

The author proceeds to state the ground of his belief that the descent of the upper layers of air is caused by the rain, and he thus explains the frequent continuance of the thunder clouds in a state of strong electric tension unceasingly spent and renewed. Every nearly vertical fall of water produces a wind directed towards the earth. All waterfalls produce a strong current of descending air, which spreads itself out over the ground, and gives birth to what has been called the *vent des cascades*. This wind for large falls of water forms in certain cases a veritable tempest near the foot of the fall.

In the same way each drop of rain is the source of a vertical elementary current of air, which takes it birth at the very point where the rain begins to fall—that is to say, in the interior of a cloud. The larger the volume of the drop the greater the current of air. Thus every shower necessarily drags with it a descending wind whose source is in the same cloud as that of the drops of rain; and the more heavy the shower the greater the intensity of this wind.

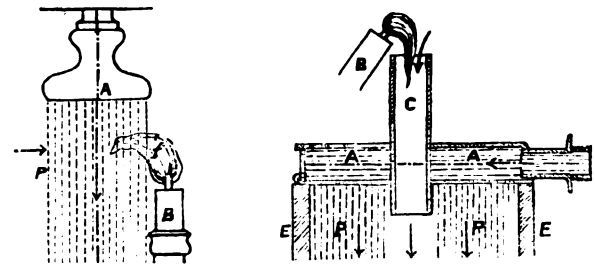
The rain continues to drag the air with it more or less as long as it continues to fall, so that it is only set free when it reaches the earth, and then escapes laterally without being able to re-ascend. There will necessarily be produced, then, in this cloud and at the source where the rain is formed, a considerable atmospheric depression, which must certainly be compensated by an attraction of other air which can only come laterally or from above. When the shower is of considerable extent, towards its centre it must be from above only.

When the rainy clouds are very dense and high up—which is frequently the case in summer—the air attracted from the upper regions ought to bring with it a provision, constantly renewed, of positive electricity, of needles of ice from the cirrus and little globules of water in the state of surfusion. This mixture of ice needles and of globules of water below zero will be more than sufficient to counterbalance the heating of the upper air, which will be produced by its increase of density, and the mean temperature of the rainy cloud might fall considerably below zero. The author thinks that the following facts thus receive an explanation:—

First.—The rapid renovation of the electric tension in most storm clouds, despite the continual discharges of their electricity in the earth, whether these manifest themselves by a succession of lightning flashes, or take place in an invisible manner in consequence of the great electrical conductivity of the lower air strongly charged with rain and moisture.

Second.—The accidental formation of hailstones, which make their appearance more especially in the months of July and August, when the storm clouds are most dense and elevated.

The figures show experiments which illustrate the drawing down of the air by a fall of water. Fig. 1 represents the rose of a watering pot, from which the water descends vertically. If a lighted taper is brought close up, as shown, the flame will be seen to be attracted into the column of water drops. Fig. 2 represents an apparatus which the author has had constructed to imitate, on a small scale, the drawing down of the upper air, which showers of a certain extent produce above the area from which they start. In this apparatus the rose of the watering pot is replaced by a reservoir, A, which has the form of a flattened cylinder of large diameter. The bases of this cylindrical reservoir are traversed normally by a central tube open at both ends. The numerous holes, pierced on the under face to produce the shower, surround this central tube. Finally, an exterior cylindrical envelope of stuff, E E, serves to prevent any lateral attraction of air. The reservoir A being placed horizontally, if we pass water into it the rain which



falls produces an inspiration of air through the tube, which can be rendered visible by bringing near the top of this tube a lighted candle, as shown in the figure.

ELECTRIC TRAMCARS.

The editor of the *Centralblatt für Electrotechnik* says that lately he had the opportunity of being present at the trial trip of Herr Huber's first electric tramcar in Hamburg. This tramcar is constructed after the Julien system, which was distinguished at the Antwerp Exhibition with the first prize or great diploma of honour. Thus the electric vehicle was brilliantly victorious in the competition over the locomotive, a result which would not have been thought possible a few years ago.

Among the definitions of requirements for the competing systems were the following:—Freedom, more or less perfect, from escaping steam; freedom from smoke and sparks; freedom, more or less perfect, from noise; an exterior agreeable to the eye; facility with which the motor can be detached from the carriage; arrangement of the brake so that this may act upon the greatest possible number of wheels of the vehicle or train; disguise of the motor, so that it may be hid as much as possible from the public eye, although it is easily accessible and manageable in all parts for the machinist; ease of intercourse between the driver and conductor of the train; protection of the working parts against dust or dirt, evenness and quietness in the motion; arrangements to go round curves of small radius; simplicity of construction; the relation of the dead weight to the number of seats; facility with which the motor can be got ready for service; the greatest possible daily length of service without other detention than that which is required by the service; working expenses per carriage, and per kilometre; the smallest use of burning materials, and the same of lubricating materials.

The electric carriage was considered to most nearly meet all these requirements. Even in the matter of consumption of burning material the indirect electric working of the motor was found cheaper than the direct steam working, because cheap pit coal could be employed instead of the more expensive coke.

The Julien system concerns, first, improvements in the accumulators, and second, the contrivance of the car. The improvement of the accumulators consists in that the lead is replaced by a metal composition called Julien metal, which secures a greater endurance of the accumulators.

Mr. Huber has entered into association with the directory of the Hamburg Roadway Company, whereby shortly two electric cars will be tentatively worked. The one which we are describing contains 33 seats, and weighs with full equipment 4,830kgs. Of this weight 1,200kgs. is that of the accumulators. The accumulator consists of 96 cells, of which every three are united in a single three-celled holder Glass and brittle substances have to be dispensed with for fear of breakage. The cells are formed out of a new material, something like hard gutta percha but rather more flexible. Each cell contains 15 plates, seven positive and eight negative. The plates have a surface of only 134 by 147mm., and are about 4mm. thick. The charging requires about eight hours.

The accumulators are distributed in eight low wooden boxes, of which four are stowed away on each side of the car in the space under the seats. The boxes move along greased slides, and can easily be drawn out by opening two long traps in the side of the car. In the car house the vehicle is drawn between two tables, on which the charging takes place, and the accumulators are slid from the car on to the tables. The shunting of the boxes, both in the car and on the charging table, takes place automatically by a contact apparatus both simple and sure, constructed by Mr. Huber.

Four double conductors lead from the accumulators in the car, which are shunted in four groups, to the Julien commutators, of which one is placed on each perron. By turning a handle which forms part of the key of the commutator six different positions can be given to it, viz.:—

(1) So that there is no connection between the accumulators and

Digitized by Google

the motor. (2) The four groups of accumulators are shunted in parallel arc and placed in connection with the motor. (3) The groups are shunted two and two in parallel arc, and the two pairs in series and in connection with motor. (4) Two in parallel arc behind the other two in series. (5) All four groups in series. (6) All four groups in parallel arc, but unconnected with the motor. The commutator stands in this position with the key up during the periods of stoppage.

A great advantage of this arrangement is that different velocities are obtained without the application of any current regulator or resistances.

The positions (2), (3), (4), (5) of the key correspond to the E.M.F.'s 48, 96, 144, and 192 volts on the motor, and its velocity again corresponds to these E.M.Fs. The normal current amounts to about 18 amperes, while on inclines and curves the current may sometimes reach 80 amperes. The motor is a Siemens series machine, model D, with about 0·6 ohm resistance, which is hung under the car, and gives out its power by means of hemp cords to a blind axle between the two wheel axles, and from hence the power is given out by means of chains to the wheel axles. The hempen ropes are protected as much as possible against the influences of weather by a special preparation.

The reversal of the direction of rotation of the machine is brought about by changing the position of the brushes; there are two pairs of brushes about 90 deg. apart, of which only one pair rubs at one time.

One charging is sufficient to drive the car 50km. Since such a car has to traverse about 100km. daily, one change of the accumulators is enough.

The charging of the accumulators is performed at the inn of Schürbeck. Here there is a little machine house built on, with a Lilienthal motor of 10 horse-power fastened to the wall, which receives its steam from a little boiler with a hose. The steam engine is condensing and works extremely economically. It drives at present one contact-machine of Schwerd of Connstatt. The velocity is controlled by a Tachometer of the Buss system, whilst the electrical quantities are regulated by instruments of Paterson and Cooper, Breguet, Ayrton and Perry, and Manuel. These instruments differ by 20 to 30 per cent., whence the value of their indications appears to be somewhat doubtful.

The trial trip passed off brilliantly. The coachman showed that he knew well how to manage his electric horses. A trial on the efficacy of the brake at great speed gave a surprisingly good result. The motion of the vehicle was essentially quieter and pleasanter than one is accustomed to in horse-tramways, also quieter than on the Frankfort electric tramway. The violent jerks, which are very unpleasantly noticeable at starting in the Frankfort car, are not present in the Hamburg one. The car starts softly, and the increase of velocity takes place almost uniformly.

SOUTH KENSINGTON EXAMINATIONS.

(Continued from page 142.)

Voltaic Electricity.

10. How could you boil water by means of the current from a voltaic battery? Give a sketch of the apparatus you would use.

A.—Join the thick copper wires A C and B D coming from the opposite ends of a powerful voltaic battery by means of a coil of thin wire of some metal having a high resistance, such as platinum or iron, and place the coil in a small vessel filled with water.

Owing to the resistance of the coil of thin wire being very great compared with that of the rest of the circuit, the greater part of the heat generated by the action of the current flowing through the circuit will be evolved in the coil, and if the battery be a powerful one, and the quantity of water not too great, the heat generated will be sufficient to make the water boil in a short time.

11. One end of a copper wire is fastened to the copper end of a battery, and one end of copper wire is fastened to the zinc end of the battery. What happens if the other ends of these two wires are put side by side (but not touching) into a solution of sulphate of copper?

A.—1. Owing to the circuit being completed by the solution of sulphate of copper, a current of electricity will be set up, flowing from the copper end of the battery through the solution of sulphate of copper, as shown by the arrows.

2. The sulphate of copper will be decomposed.

3. The copper, which will be liberated at the end of the wire connected with the zinc plate, will be deposited on the immersed portion of that wire, while sulphuric acid (hydric sulphate) will be formed in the neighbourhood of the wire connected with the copper

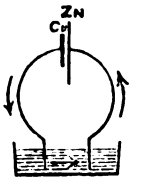


plate of the battery, and will gradually dissolve the immersed part of that wire, and so keep up the strength of the solution.

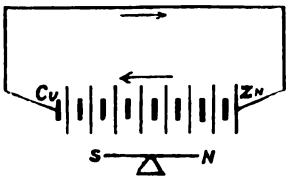
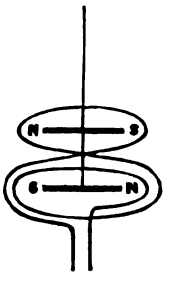
12. A number of galvanic cells are connected together in a row so as to form a battery. This row is laid on a table so as to lie N. and S. The zinc is to the N. The poles of the battery are connected together by a wire, which passes from one pole, up one wall of the room, across the ceiling, and down the opposite wall to the other pole of the battery. How will a magnetic needle be affected which is placed under the table and just below the battery?



A.—The magnetic needle, being immediately underneath the battery, will be acted on by the current flowing through the battery, and will not be sensibly influenced by the distant current flowing in the opposite direction across the ceiling.

As the current through the battery is flowing from north to south over the needle, the north seeking end of the needle will be deflected towards the east.

13. How is it that a galvanometer with astatic needles is more sensitive than the same instrument would be if furnished only with a single needle?



A.—If two magnetised needles, equal in every respect, and equally magnetised, be fastened rigidly together with their axes parallel, and their corresponding poles pointing in opposite directions, as shown in the diagram, the earth's magnetic force will have no directive power on the combination. If such a combination were used in a galvanometer, the only directive force determining its position of equilibrium when no current was passing, would be that due to the torsion of the suspending fibre. By using a fibre in which only a a small restoring force was called into play by its torsion, the combination could be made very sensitive to the action of even very weak currents.

It is, however, practically impossible to manufacture such a system, for even if the needles, to begin with, were magnetised to an exactly equal extent, and were fixed perfectly parallel, one of them would almost certainly in time become weaker than the other.

In practice, therefore, we generally use two needles, one of which is magnetised somewhat more strongly than the other, and therefore the combination will take up a position of equilibrium in the plane of the magnetic meridian (supposing a suspending fibre be used whose torsion does not produce an appreciable restoring force) in obedience to the action of the more strongly magnetised needle; but the restoring force called into play when the combination is deflected out of the plane of the magnetic meridian, depending as it does on the difference of the earth's directive action on the two needles, can be made very small by magnetising the two needles to very nearly an equal amount, and therefore a very weak current will be sufficient to produce an appreciable deflection.

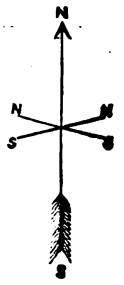
In the second place, the wire being wound round the needles, as shown in the figure, it will be seen that the effect of the current

Digitized by Google

upon each of the needles will tend to deflect the combination in the same direction. Thus we see that a galvanometer with an astatic combination of needles is more sensitive than it would be with a single needle. Firstly, because the earth's directive action upon the combination is less than it would be upon a single needle. Secondly, because the deflecting action of the current upon the combination is greater than it would be upon a single needle.

Remarks.—There is another form of astatic galvanometer in which the two needles are fixed together in the same way except that they are not quite parallel, though very nearly so.

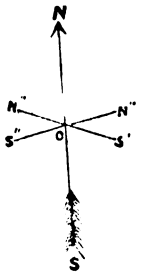
When we look down from above on such a combination we shall see the two needles projected upon a horizontal plane, as shown in



the accompanying figure, where the want of parallelism is very much exaggerated for the sake of clearness.

It is easy to see that if the two needles were magnetised with exactly equal strength, such a combination would take up a position of equilibrium with the plane of the magnetic meridian bisecting the vertical planes drawn through the needles, as shown by the arrow in the diagram.

If one of the needles N′ S′ be rather more strongly magnetised



than the other one, N″ S″, the combination will set itself so that the angle N′ O N is somewhat less than the angle N″ O N.

As, however, the two needles are very nearly parallel, and as nearly equally magnetised as possible, the combination will set itself so that the two needles are sensibly perpendicular to the plane of the magnetic meridian.

14. If a charged battery is to be kept for some time ready for use, why is it important to take care that the ends of the battery are not connected together outside the battery?

A. If the ends of the charged battery are connected together outside the battery, the circuit will be closed, and therefore an electric current will be set up, accompanied by chemical action in the battery and a consequent waste of material.

(To be continued.)

LIGHTING EXHIBITION AT BRUSSELS.

The Belgian Society of Engineers has opened in the Brussels Bourse an interesting exhibition, both modern and retrospective, of apparatus for illumination, including old Grecian oil lamps, the first oil lamp that lighted the streets of Paris, a quantity of old candlesticks, recent improvements in lighting by gas and petroleum, and a few elegant applications of the electric light. An interesting historical object is the first Foucault regulator, borrowed from the laboratory of the Brussels Municipality, which served to light up the Rue Royale, Brussels, on the occasion of the twenty-fifth anniversary of national independence in 1855. The square, horizontal carbons are mounted on trucks working on incline planes, being regulated by clockwork connected with the electro-magnet.

The Brussels company, "L'Electrique," whose automatic electric tramcar gained the diploma of honour at the Antwerp Exhibition trials of last year, arranged a small lighting installation to show the several applications to houses, offices, and vessels. The fittings, with fusible plugs and bayonet joints for the glasses, are very strong, and yet present an elegant aspect. One lamp for domestic purposes has a coloured glass enclosed in an opal globe, for use where a strong light is not required, so as to preserve the sight. A passage or hall lamp is covered by a trunco-conic glass in the form of a shield or rather buckler, cut with innumerable facets for distributing the rays. In the centre, where the light is strongest, the glass has a boss which still more effectually diffuses the light. An office desk is provided with a movable standard, carrying a shade and two incandescent Lane-Fox lamps of about 12 candle-power, the current for which is supplied by a small battery of twelve accumulators, having plates of amalgamated lead, which is stronger than ordinary lead and lasts much longer. These accumulators, which are contained in one of the compartments of the desk, are of the same type as those used for the electric tramcar at Antwerp. A four-branch lustre and a pendent electrolier produce an agreeable effect, while another form of lamp with shade attached to the wall, resembles an ordinary gas bracket, contacts being made by switches in the form of stop-cocks. An electric torch consists of a Lane-Fox incandescent lamp fixed to a handle and protected from injury by a wire cage, so that it can be thrust into corners without fear of breakage. The conductor, which passes through the handle, is strong, flexible, and well covered.

Besides some miners' safety lamps, with electrical means for the detection of firedamp, M. Léon Somzée has sent his apparatus for the production of light by incandescence and by infinitely small arcs. The exciting organs consist of but slightly conductive and extremely subdivided substances, such as metallised carbon powder and combustible gas. It combines the advantages of the arc and incandescent systems—that is to say, economy, divisibility and intensity—while, at the same time, ensuring continuity of the circuit, rendering the light relatively independent of variations of the current, and obviating a too great concentration of luminosity.

M. Somzée also exhibits his automatic regulating lamps, in which the arc and incandescent systems are again combined. The principle consists in producing incandescence in a thin carbon, and developing the voltaic arc round a *colombin** fixed to the second rheophore, which is of large sectional area. This arrangement gives an arc light terminated by the incandescence of the carbon. The arc is invariable, for its resistance depends on the ratio of the sections of the *colombin*, and of the incandescent carbon, this ratio being absolutely constant. The arc is practically uniform, for its development is guided by the *colombin*; and the carbonaceous mass is directed towards the interior of the arc. The wasting away chiefly takes place from the thin carbon, its replacement being effected automatically without the aid of mechanism. It follows from the fact that the arc is developed round the *colombin*, between the carbon and the large block, that the tension current may have a large surface for a given sectional area of carbon, so that both the conductivity and the duration of the carbon increase. The luminosity is considerable, seeing that it is an arc lamp that can be maintained by a continuous current, while the light may also be divided. The interposed refractory substance may be movable, in which case its degree of volatilisation or disaggregation is independent of the wear of the large carbon. It may, on the one hand, be fixed, in which case it must disappear concurrently with the combustion of the carbon. In either case the extent of the arc, and, consequently, the intensity of the light, may be as great as can be maintained by the current at disposal, without the resistance varying or exceeding the assigned limits on account of the thickness of the insulating substance.

M. Léon Lennaerts has installed two appliances constituting a happy combination of gas with electricity. In case a fire should break out in a building lighted, in the ordinary manner, by gas, it is the main gas supply which constitutes the greatest danger. M. Lennaerts has succeeded in closing the meter automatically, and also in utilising this motion of the lever for so setting a switch that the current from a secondary battery or dynamo shall light up some incandescent lamps, where otherwise darkness might prevail through the cutting off of the gas supply. This is brought about by the lever of the gas meter, which is counter-weighted, being held in the position of "open" by a fusible wire, and its fall, on the wire being fused by the current, working the switch which sends the current through the lamps. In order to inspire the utmost confidence in this arrangement, a safety lead, consisting of two wires kept apart by a combustible insulating substance, is disposed about the building, so that contact is made automatically on a fire breaking out.

M. Lennaerts' other apparatus is for electrically opening or closing the main supply of gas from any desired point or points, without the necessity of going down into the cellar, owing to which trouble so many meters are never closed at all. Moreover, as soon as the stop cock is closed, any burner that may not be turned off gives warning of the fact by an electric bell, which continues to ring until the matter is set right, while an indicator shows exactly which burner is not turned off.

The Société Nouvelle des Produits, of Namur, shows some enamelled sheet iron reflectors of various forms for electric lamps.

* An intermediary non-conducting substance.

PROF. FORBES' CANTOR LECTURES.

LECTURE V.

I commenced my last lecture by showing you the remarkable experiment made by Prof. Œrsted. This experiment has been spoken of by some as having been an accident. At the moment that he saw the influence which a wire carrying a current had upon a magnet, he was trying to detect the influence in a totally different manner. He was trying to detect the influence of the heat generated in a wire upon a magnet. Instead of finding that, he found the remarkable result which formed the basis of our demonstrations in the last lecture. I say by some it has been said that Œrsted's experiment was the result of an accident. I protest against any such interpretation being put upon it; it shows comparatively feeble knowledge of the means of progress in scientific discovery. It is by such constant labour and the readiness to grasp all unexpected phenomena that present themselves that the greatest discoveries have been made. Were we to say that the philosopher studying in his laboratory after numerous experiments happens to come across something that he never knew before—were we to say that that was an accident, why then we should have to say that the discovery of the planet Uranus was an accident, and the discovery of many continents and islands over the world were accidents; in fact, that half the discoveries of philosophers in their laboratories had been accidents. As the result of that brilliant discovery of Prof. Œrsted we saw last week that several conclusions could be drawn—the continuous rotation of a magnetic pole round an electric current, the motion of a wire carrying an electric current in the neighbourhood of a magnet, and the attraction or repulsion of two parallel currents, according as they were in the same or in opposite directions. The discoveries of Faraday and Ampère are necessary conclusions from Œrsted's experiment. At the same time, that does not detract from the originality or the merit of these great men, who followed out the experimental work, and proved the truth of those facts which were new to science. And so it is in the present day. Frequently we find new discoveries which, upon investigation, are found really to be deducible from what we knew before; but that in no way detracts from the merits of those investigators who, by their laborious researches, have introduced to us facts which at the time were new to science. And especially is this the case in electrical science. Frequently we have new facts presented to us that none of us were before acquainted with, and it is common for us to say that such facts were deducible from the known theory of electricity. That may be so, but it does not detract from the value of these new researches. I will, with your permission, before going on to the question of induced currents, which is a continuation of the deductions which may be made from Œrsted's experiment, illustrate the subject of the last lecture by means of a different apparatus, of great beauty, and one which, with the same fidelity, proves the truth of the rotation of a current of electricity round a magnet. I have here a globe partially exhausted of air. The density of the air within this globe is very much smaller than the density of the atmosphere around us. I shall pass a current of electricity through this globe, passing it along the outside of the tube, which you see going down from the top through the middle of the globe. Within that tube I have a piece of iron with a coil round it, so that with the wires connected to the battery I am able to magnetise that central piece of iron either with the north pole downwards or with the south pole downwards. We saw before by numerous experiments that when a current is travelling parallel to a magnet it tends to rotate round it in one direction or another, according to the direction of the poles of the magnet. In the experiments in connection with my last lecture we always used a solid body—generally a copper wire—to convey the current of electricity. In this case I am going to pass the current through attenuated air. Now, when we send a current through this induction coil you see a current of electricity passing parallel to the magnet from the top down to the bottom. [Shown.] I am now able, by means of a commutator which is on the table before me, to send a current through the coil within the tube in either direction, so that I can magnetise that bar of iron in either direction at pleasure. I will magnetise it with the north pole downwards, and you see a continuous rotation of the electricity round it. I will now reverse the direction of the magnetisation, and put the south pole downwards in place of the north pole, and the current stops, and then commences to revolve in the opposite direction. [Shown.] All the phenomena of movement of a wire carrying a current were shown in the last lecture to be due to the presence of a magnetic field. The wire itself acts in such a way as to create a magnetic field in its neighbourhood. The magnet itself, however, may be looked upon as an agglomeration of electric currents, and I showed you a model giving the ideal magnetic molecules. Let us consider the question now of Œrsted's first experiment, or one of the experiments that follow directly from it. I will take a coil of wire with a magnetic pole in its neighbourhood. When we pass a current of electricity through that coil it moves the magnet—moves it against the force of terrestrial magnetism which is trying to hold it in its place. Now, the principle of the conservation of energy proves to us that a motion like that of a magnet towards the coil or away from it cannot take place without the consumption of energy. I have a current of electricity passing through this coil, and as soon as I bring it near to the magnetic pole energy is consumed. What is the energy which is consumed? Where does it disappear from? Clearly it must disappear from the energy of the current which is circulating in the coil. In other words, when the magnetic pole approaches the coil the energy of the current is diminished. The diminution of this current on the approach of the magnet towards the coil simply means that an inverse current is tended to be set up by the approach of the magnet; in other words, by a consideration of the principle of the conservation of energy we are able to deduce from Œrsted's experiment this remarkable fact, that when the pole of the magnet approaches the coil, a current is generated in the coil by the influence of their mutual approach. However desirable it may be to trace the connection between all these different phenomena, the facts themselves must be demonstrated, and we must see the experiments before us in order to convince ourselves of their reality. I have upon the mantelpiece there a small galvanometer, which consists simply of a suspended magnet attached to a highly polished mirror, and placed in the centre of a coil of wire which surrrounds the magnet. When the limelight is thrown upon it it will deflect a beam on the scale which you see on the wall there. The vertical wire is placed in the position which would be occupied by the slide of a magic lantern, so that we should have the image of the wire moving upon the screen in accordance with the motion of the magnet within the coil of wire. The ends of the coil of wire are carried away here [indicated], and are continuously connected together, so that that coil of wire has at present no ends, for the two ends come over here, and are coiled up in half a dozen parts. I hold in my hand here a magnet with the north pole pointing towards you at the present moment, and my object in this experiment will be to prove the truth of the deduction that we made just now, and to show you that by the approach of the magnet simply into a coil of wire like that we are able to induce a current of electricity in the wire which will circulate round the coils of the galvanometer, and so deflect the compass needle. [Experiment.] There you see the bar slightly oscillating, owing to a slight movement of the compass needle. At the present moment it is my intention to reverse the north pole of the magnet within the coil of wire, and as I do so the spot of light moves towards the right. When I move the north pole into the coil of wire in this direction the spot of light moves to the right, and if our theory be true it would immediately follow that on the withdrawal of the north pole from the coil of wire we should get a motion in the opposite direction. I withdraw the magnet, and the spot of light moves to the left. I will now introduce the south pole instead of the north. I force the south pole in, and the spot of light moves to the left—the opposite direction to what it did before. [Shown.] I will now complete the set of experiments by withdrawing the south pole, and the spot of light in this case ought to go to the right. [Shown.] There are a vast number of experiments which were undertaken by Faraday, who made this brilliant discovery, explaining the application of these general principles. And just as we have found that that experiment with a magnet and a coil is a direct result of the brilliant experiment of Prof. Œrsted, so we shall see that other experiments which were performed by Faraday are the necessary and natural consequences of the results arrived at by the French philosopher Ampère. Ampère found that when two coils of wire were placed in proximity to each other, and currents of electricity were flowing through both, there was attraction or repulsion between them according as the direction of the currents of electricity were the same or opposite to each other in the two coils. Exactly similar reasoning to that which I used a short time ago upon the principle of the conservation of energy proves to us that this energy which is thus used up is derived from the energy in the currents, and that at the moment of the approach of the two coils there must be a diminution in the strength of the currents of electricity; and if there be a current of electricity in only one of the coils this approach of the two coils together must cause the creation of an inverse current in the second coil. I have connected now one coil to the galvanometer, while the other is connected with a commutator here, by means of which I am able to send a current of electricity through it. At the present moment there is no current passing through it. I have now got a current passing through my coil, and I approach the coil towards the one which is connected with the galvanometer. As I approach it the spot of light is moved to the right. That shows the creation of a current in an induced coil inverse to the direction of the current in the inducing coil when the spot of light went to the right. When I withdraw the two coils we ought in the same way to see a motion of the spot of light to the left. I will now reverse the current of electricity, and the opposite effects ought to take place. We shall now be able to prove that a current induced in a second coil is always in the opposite direction to the inducing coil. [Showing.] I approach them and the motion of the spot of light is to the right. In conclusion, I will show you next that when I keep the two coils together and make or break a circuit the same effects take place. I first make the circuit and the spot of light moves to the right. That is equivalent to the bringing of the two coils together. I will now break the circuit and the spot of light moves to the left, which is equivalent to the opposite effect of withdrawing the two coils. [Showing.] There is one more experiment that I will show you in connection with this, and that is the enormous influence of the introduction of a bar of iron into these coils. We have seen that the whole of these electro-magnetic effects are due to the production of magnetic fields in the neighbourhood of the wires. If, then, I introduce a bar of iron partly into the secondary and partly into the primary coil, and then make and break the circuit, the spot of light will be found swinging right round. [Showing.] Faraday worked at this experiment a great deal, and tested the accuracy of his conclusions in a variety of ways. It is all very well for us just to look at a few experiments like these, and to say that they are the necessary conclusions from Œrsted's experiment. But that is not sufficient to convince the philosopher when he is for the first time investigating these new facts, and it was the laborious study on the part of Faraday that completely established the whole of the truth of the laws of induction. Faraday showed that the terrestrial magnetism was sufficient to induce a current of electricity in a moving wire, and it is evident that this must be the case. I will show you that it is so by means of this apparatus which I have here. I will place this coil of wire so that I can rotate it about a horizontal axis which will cut the magnetic field created by the earth's magnetism. The lines of force in the earth's magnetism in a horizontal plane are going in a direction perpendicular to the axis about which I rotate the coil. You see, then, that at any one moment while this half

Digitized by Google

of the coil is cutting the lines of force in one direction the other half is cutting the lines of force in the other direction. It follows from this that a current of electricity will be created in the one half of the coil from your left to your right, and in the lower half of the coil it would be at the same time from your right to your left. The combined effect of this is always to produce in both parts of the coil a continuous current in one direction round the coil. But after this has been accomplished at one half of the revolution the tendency during the other half revolution is to create a current in the opposite direction. It would be in the same direction in space, and therefore in the opposite direction in the wires. In order to get over that difficulty, what is called a commutator is introduced here, by means of which the direction of the currents which are taken away here to the galvanometer are reversed at each half of the revolution. Thus, if there is a reversal of the direction of the current in the coils of wire at each half of the revolution, and also a reversal of the connections of the two wires to the galvanometer. the current through the galvanometer must remain always in the same direction, and thus by turning the handle rapidly we are able to add together the effects of half rotations, and we shall have a continuous deflection of the spot of light on the scale. I will rotate this coil, and you see a movement of the spot of light to the right. I will now rotate it in the opposite direction, and it moves to the left. I will get up a swing now to the right and to the left, rotate to the right and rotate to the left, and by showing that swing you are able to show perfectly easily the creation of these currents of terrestrial magnetism. I will intensify your belief in this by causing the spot of light to come to rest. [Shown.] The generation of currents of electricity by this means—that is to say, by the motion of a magnetic field and the motion of a wire in a magnetic field—has given rise to practical applications of the very highest importance, and when speaking of those powerful currents of electricity which are created by our dynamo machines I will show this. But I may at least introduce one illustration here of the intensity of the currents which can be so induced. I have upon the table an apparatus consisting of a horseshoe magnet with soft iron pole pieces, and around these pole pieces are ribbons of wire, and there is a keeper placed upon the poles here at the ends of the pieces of soft iron. Thus at the present moment there is an intense degree of magnetisation in these iron cases round which the coils of wire are placed. If I suddenly remove the keeper from the magnet I diminish the amount of magnetisation in the soft iron pole pieces to a very great extent. This change in the intensity of the magnetism inside the coils is equivalent to the passing of lines of force through these coils. The result of this diminution in magnetism is to create an intense E.M.F. in the wires. That E.M.F. which is created may be utilised for several purposes. At the present moment I have placed upon it one of those fuses generally known as Abel fuses, from the name of our president, who constructed them for explosive purposes, and for use in mines, and the current of electricity which we shall be able to get simply by withdrawing this keeper from the magnet will be able to explode the fuse, which is connected to the wires which surround the soft iron poles. [Shown.] You all saw the explosion from that little detonator. That, I need hardly say, is a current of very great intensity indeed, of very short duration, but very powerful during the short time it lasts, and capable of overcoming a very great resistance.

There are many other experiments illustrative of induction which I should like to show you. Here is one of a very important character, and very instructive, when we see the reason why it works. I have a copper disc supported upon a vertical axis, to which I have the power of giving very rapid rotation. Above that I have a sheet of glass considerably larger than the copper disc, and not touching it, and fixed upon the centre sheet of glass is a pivot with a compass needle attached to it. When I rotate the copper disc the compass needle is seen to rotate in the same direction. There are no air currents capable of influencing it, because the glass plate shields it from all currents of air. This was a discovery of Ampère, and Faraday was the first to show that it was simply a consequence of these induced currents which he had been investigating. And now let us first see how the explanation is arrived at. Consider that above this north pole a copper disc is moving, and therefore a current of electricity is generated in the copper disc; but when the current of electricity is in the neighbourhood of the pole, it causes that pole to move, and therefore the rotation of the copper disc has the double effect of first inducing an effect in itself, and then reacting owing to the existence of the current upon the magnet pole itself, and so being able eventually to pull it round in the same way. You see the motion of the needle and the force of the earth's magnetism counteracting it; still it is able to overcome the earth's magnetism. Now it is rotating in the same direction as the copper disc, and it is gradually acquiring velocity, and would eventually rotate at almost exactly the same speed at which the copper disc is itself rotating. This phenomenon of Faraday was also examined by other people, and there are a vast number of instructive results which come from modifications of this experiment. I am only going to show you one modification, which was first shown to me by Dr. Guthrie, it is a very striking experiment indeed. I suspend here a horseshoe magnet, so that the poles are just above the rotating copper disc. There is an effect which I wish to show you, which is due to what has been spoken of as electric momentum—that is to say, that the electric current has a species of momentum very much as a moving body has a momentum. I think we are very certain that electricity is not a material substance, yet it is influenced by electromotive force, very much as material substances are influenced by ordinary forces. And there is such a thing as momentum in connection with it—that is to say, a current once created tends to maintain itself. One of the consequences of this is that when we rotate the disc the action, whether attractive or repulsive, lasts for a considerable time, and it does not take place at the same points where you expect it to take place if we did not consider electro-magnetic momentum. If we did not consider this momentum as any point of the copper disc is approached towards the magnet, it would be repelling it. But any point of the copper disc receding from it would be tending to attract it. If there were no electro-magnetic momentum, the upward motion tended to be produced by the approaching part of the plate would be equal to the downward pull of the receding part of the plate. But if there be an electro-magnetic momentum, so that the current once established tends to keep itself going, then the action of the approaching part would be nearer to the pole than the action of the receding part, and therefore the repulsion afterwards would be in excess of the attraction downwards produced by the receding part of the copper disc. [Shown.] It would lead me very far if I were to go on to consider all that is due to the phenomenon of electro-magnetic momentum, but I shall have a few words to say about it presently. I want, however, in the first place to show you an experiment showing the powerful nature of an induced current when a good conducting material is moving in the neighbourhood of a magnet. I have here a copper medal placed between the two poles of a powerful magnet. I shall give this medal a considerable spin. I shall twist the thread which suspends the medal between the poles, and when I have twisted it so that it will maintain the spin for a good long time, I shall allow it to spin freely. As soon as I create a magnetic current by connecting this electric magnet with a powerful battery, this copper medal will be creating induced currents of great intensity, as it cuts the lines of force of the magnetism. The result of that will be that these currents will react upon the magnet, and the magnet will always tend to stop the motion which gives rise to the currents, and, therefore, as soon as I let it spin, and then connect the magnet with the powerful battery, you will see the rotation of the copper medal stopped. It is now rotating rapidly. I make contact, and immediately the rotation of the copper medal is stopped. The higher the velocity it has the greater is the rapidity with which it is stopped. [Shown.] When we use a large mass of metal like this the intensity of the current which is created in it depends partly upon its form and partly upon its conducting power. The greater the conducting power of the metal the greater is the effect of this kind which is produced. Had I used a comparatively bad conducting material, such as lead, the effect would not have been nearly so marked; but by using a highly conducting material, such as copper, the effect was very appreciable indeed. Thus the intensity of induced currents in bodies of the same form, subject to the same inducing influence, depends upon their conducting power. And this property has been utilised by Prof. Hughes in a very ingenious instrument which he has called the induction balance, in order to detect minute differences in metals; and not only so, but he is able to measure the difference of conductivity of different metals, and of the same metal with slight variations of impurities in them. The apparatus I shall be able to show you. But in speaking of induction it is essential that attention should be drawn to this very beautiful apparatus. It consists essentially of two pairs of coils—one pair at each side of the board, one coil rising above the other, with a hollow cup in their centre. When we send an interrupted current through one of these coils, an induced current is created in the second coil by the action of the one through which the battery is sending the current, but there is nothing more than that. In the centre of the coils we have now placed a mass of metal. The currents are now also induced in that mass of metal, and they should re-act upon the secondary coil, too, and the intensity of the reaction can be shown by connecting a secondary coil with a telephone; this was the means by which Prof. Hughes examined it. He got sounds from the telephones which depended on their intensity, and by arranging two pairs of coils in this way and connecting them in such a manner that when there was no metal in the centre of either pair of coils the one counteracted the other so that no sound was heard on the telephone, but so soon as the metal was introduced into the one or the other the balance was disturbed, and effects were apparent on the telephone. And so delicate was this test that the placing in the centre of two coils two sovereigns was actually heard, and he was able to trace a difference in the effect either due to resistance or due to the difference of form or due to the difference of material of the two sovereigns. The two sovereigns being turned out at the same time you might naturally think they were the two likest things in the world, yet they were found to be different by this telephone. I now show you some specimens of copper and the difference of their conductivity upon the scale which you see here. [Indicated.] This specimen low down on the scale is the ordinary commercial copper, and its conductivity is indicated by that short distance [indicated], while high up there we have a higher conductivity of copper which is used for all refined electrical researches and which is nearly pure. The conductivity is represented by nearly three times the distance, while beyond there is a copper which Prof. Hughes found produced a conductivity very considerably in excess of that of the finest copper which had been taken for other experimental purposes. I am afraid the time will not permit me to explain this more recent and exceedingly beautiful apparatus of Prof. Hughes. Perhaps it may be better if I leave it for the present and speak of it in the next lecture. But I will simply briefly allude to this induction bridge, as he calls it, and tell you the object for which it was designed. We all know now that when a current of electricity is passing through one wire, and there is another wire in its neighbourhood, that an induced current is brought about in the other in the opposite direction. If the current came through both these wires simultaneously, each one would at the same moment be tending to create a current in the opposite direction in the other wire. Thus, the current is diminished owing to this mutual influence between the two wires, and this effect arises from their being both conductors. I will simply say that this apparatus was designed for the study of this property of self-induction which is possessed by wires, and it was by means of this apparatus that Prof. Hughes was enabled to enlarge our knowledge very considerably. The lecturer having demonstrated the theory of induction by means of a telephone proceeded to say: I will now show you a few other experiments.

Digitized by Google

This induction coil consists of a primary coil of wire wound round a bundle of iron wires; this is connected with a battery, which enables us to make and break contact in succession; and we have alternately a current and no current passing with interruptions. Around that is a high resistance coil of wire, and the making and breaking of the current on the primary with the influence of the iron which is in its centre causes induced currents to be created on the outer coil, creating at the terminals of the two wires an enormous difference of potential, such as we obtain from the Wimshurst machine, which we were examining the first day of these lectures. I will show you the almost continuous charge between these two points, when we make and break the primary circuit. [Experiment.] You see what an enormous length of spark we are able to get. This enormous length of spark is obtained from four cells in the battery, which of themselves could not produce a spark a thousandth part of the length which we are able to get in this way. I will now put a Leyden jar in the secondary circuit. By this means we do not get anything like so long a spark, but we get a much greater quantity of electricity, and the effect is quite as striking as before. Here I have two specimens of glass which were on the table when I was speaking to you about the differences of potential in my first lecture. One is a thick piece of glass 1in. in diameter, which was pierced from the spark of Mr. Spottiswoode's machine. The other piece of glass has been pierced by the machine before you, and it is very beautiful to see the nature of the discharge through the glass. Here I have half-a-dozen of Abel's fuses, which we shall explode altogether at the same time in series. [Shown.] I will now show you—as we have this apparatus on the table—a very beautiful form of discharge. This jar has a conductor from the top, passing through an insulated tube down into the interior of a tumbler, where it consists of a flat disc of metal. Beneath is another flat disc, on which the tumbler is supported. The tumbler itself is made of fluorescent glass, and the discharge cannot pass from pole to pole, but has to mount up and pass over the lip of the cup. [Experiment.]

LEGAL INTELLIGENCE.

United Telephone Company (Limited) v. Bassano and Slater.

The question in this appeal from Mr. Justice North, which came on for hearing on Monday in the Court of Appeal before Lords Justices Cotton, Lindley, and Lopes, was whether the telephone made and sold by the defendants, Messrs. Bassano and Slater, of Traffic-street, Derby, was an infringement of Mr. Edison's patent, which had become vested in the plaintiffs. The considered judgment of Mr. Justice North was given on the 27th of March and was then reported at length. The main point was with regard to the vibrating diaphragm made use of in the Edison telephone, the defendants contending that in their instrument there was no diaphragm within the meaning of the word in Edison's specification or performing the functions of the diaphragm in his instrument. The general nature of a telephone is well known. It may be popularly described as an instrument by means of which the sound waves set in motion by the voice at the receiving station are made to cause corresponding variations of resistance in a continuous electric current so that the current will at considerable distances reproduce the sound waves in the air at the receiving station. The arrangement for, so to speak, converting the sound waves into variations of electric resistance is called an "electric tension regulator." In Edison's instrument the pulsations of the voice strike upon a vibrating diaphragm, which communicates with the tension regulator, the diaphragm being between the speaking tube and the tension regulator. The defendants placed their tension regulator at the base of the speaking tube, which was attached to a board, to which the wires for conveying the electric current were fixed. The plaintiffs maintained that the board was, in fact, a diaphragm within Edison's specification, and performed the part played by the diaphragm in his instrument. Mr. Justice North having held that the defendants had infringed the Edison patent, the defendants appealed. The defendants said they could construct their instrument without the vibrating board, and asked the Court, in the event of the judgment of Mr. Justice North being upheld, to decide whether they would still be infringing the Edison patent if they omitted the board.

Mr. Bigham, Q.C., Mr. Aspland, and Mr. Claud Plumptre were for the appellants; Mr. Aston, Q.C., Sir R. Webster, Q.C., Mr. Moulton, Q.C., Mr. Micklem, and Mr. Dove for the respondents.

The hearing of the appeal was begun last Friday and concluded this morning.

In giving judgment, Lord Justice COTTON said the only question was whether the machine used by the defendants was an infringement of Edison's patent now vested in the plaintiffs. The question was a nice one. The patent was for improvements in telephones, and the essential thing was to have a continuous current of electricity, but varied in intensity from time to time by the pulsations of the voice, so that the current of electricity should reproduce those pulsations at the receiver. This object was attained by means of the tension regulator, and Mr. Edison said he made use of a diaphragm the vibrations of which acted upon the tension regulator by increase and diminution of pressure. In his specification Mr. Edison gave a general description of his instrument, pointing out the position of the diaphragm, but he did not pretend that this was the only way of acting on the tension regulator. He mentioned other possible diaphragms, and did not confine himself to any particular kind. What he said was:—"I would observe that I do not claim generally the transmission and reproduction of sounds by increasing and decreasing the resistance of the circuit, nor do I claim separately any of the parts or arrangements hereinbefore described and illustrated in the accompanying drawings, except as hereinafter mentioned, but I claim as my invention, first, in an instrument for transmitting electric impulses by sound the combination with a diaphragm or tympan of electric tension regulators substantially as hereinbefore described for varying the resistance in a closed circuit substantially as set forth." The questions, therefore, were whether there was in the defendants' instrument a diaphragm or tympan; whether there was a tension regulator substantially the same as Edison's; and whether there was a combination of the tension regulator with the diaphragm so as to perform the operation described in Edison's specification. What was a diaphragm according to the proper construction of the specification? It was necessary to see whether the word was used as a term of art. The scientific witnesses had not taken the word in any extraordinary sense, but they said that, having regard to the addition of the word tympan and to the terms of the specification, the word diaphragm must be taken to mean something capable of vibrating by pulsations of the air moved by the human voice. Examining the defendants' instrument it was clear that the board acted as and was a diaphragm according to the definition given by Lord Justice Fry:—"The ordinary signification of the word diaphragm I take to be a mere partition or separation—something, as one witness said, which separates something from something else." "United Telephone Company *v.* Harrison, Cox-Walker and Co." (21 Ch. Div. at p. 734). Was it a diaphragm within Edison's specification? It was startling at first that the board to which the speaking tube was attached should be acted upon so as to vibrate and communicate the vibrations to the tension-regulator, but experiment had proved that such was the case whether one spoke through the speaking tube or not, and whether the voice was directed to the front or the back of the board. It was clear, therefore, that in the defendants' instrument there was a "diaphragm." Then was there a tension regulator substantially such as was described in Edison's specification? In his lordship's opinion there was. Edison had mentioned several sorts of tension regulators, but in that which had ultimately been preferred there were fixed blocks and suspended pencils of carbon which acted by varying the tension according to the distance between the carbon points. Substantially the same thing was used in the defendants' instrument, though the carbons were fixed to the base of the speaking tube instead of being situated, as in Edison's instrument, on the other side of the diaphragm. In his lordship's opinion the defendants' instrument was an infringement of Edison's patent, and it was not the duty of the Court to point out the exact particular of the construction to which the infringement was due. The Court would therefore not say whether the defendants' instrument would still be an infringement if the diaphragm was removed.

Lord Justice LINDLEY, in concurring, observed that the only point of difference between the instruments was that the defendants put their tension regulator between the voice and the vibrating diaphragm, while Edison put his on the further side of the diaphragm. It was no good for the defendants to say that they did not want the vibrating board. The answer was, "Then do not use it." In fact, the defendants were using a diaphragm and infringing the plaintiffs' patent. As to whether they would be infringing if they got rid of the vibrating board that question could be discussed when it arose.

Lord Justice LOPES was of the same opinion, and the appeal was dismissed with costs.

We have taken *The Times* report of this appeal.

COMPANIES' MEETINGS & REPORTS.

Australasian Electric Light, Power, and Storage Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held last Monday at the offices, 41, Coleman-street, Bank, to consider, and if thought advisable to confirm, the special resolutions passed at the extraordinary general meeting on the 11th ult. for approving, *inter alia*, the indenture, dated May 20th last, made between Edison's Indian and Colonial Electric Company (Limited) of the first part, Thomas Alva Edison, of Menlo Park, New Jersey, United States of America, electrical engineer, of the second part, and this Company of the third part. The object of the indenture, in brief, is to effect an amalgamation between the Company and the Edison Company. Mr. Benjamin H. Van Tromp presided.

The CHAIRMAN: Gentlemen, you may remember that at the last meeting when these special resolutions were submitted and approved, we were not quite aware whether the Edison Company would, on the same day, pass a series of special resolutions having the same object. I am now in a position to inform you that those resolutions were duly passed unanimously by the Edison Company, and I have no hesitation whatever in saying that we believe that they will be equally unanimously agreed to to-day. All that we have, therefore, to do is to ask you to be good enough to confirm to-day by your vote the resolutions which you passed at the meeting held on the 11th of June. I do not know that I need read them, but I will take them *seriatim*, as before. He then proceeded to submit the resolutions.

Mr. JOHN JAMES CATER seconded every resolution, and they were all unanimously confirmed.

The CHAIRMAN: Gentlemen, that concludes the business. I am very much obliged to you for your attendance, and I can assure you—having regard to the fact that you have been good enough to confirm these resolutions, enabling the Directors to complete arrangements with the Edison Company—that they will do all they can in your interest to make the

Digitized by Google

arrangement a good and profitable one for the shareholders of the Australasian Company.

Mr. PEEK proposed a vote of thanks to the Chairman and Directors for having carried out so well the arrangement which had been so long in hand. The task had been an onerous one, and in some respects difficult; but he had watched the proceedings all along, and though in some respects the original proposals had been modified, he thought that from the explanations he had received the modifications were rather in favour of the Company than otherwise. Anyhow, he thought the thanks of the shareholders were due to the Directors for their pluck and assiduity, and for the way in which they had—he would not say dragged the concern out of the mire, but certainly placed it in a much more favourable position than it was in 18 months ago. He hoped that what they had done would lead to making the Company, if not the great success originally anticipated, yet much more prosperous than it was at present. Of course, that would be a work of time, but he wished to thank the directors for what they had at present done.

The CHAIRMAN: I desire to thank Mr. Peek for the kind observations he has made, and having regard to the fact that that gentleman is the largest shareholder in the Company (he holds between 3,000 and 4,000 shares), and that he has devoted a great deal of interest, not only in consequence of that, but also because he is a man of business, in watching the progress of the Company, I need not say with what intense gratification it is to me and my co-Directors that we hear such observations falling from such a gentleman.

Mr. PEEK said he also desired to thank Mr. Duncan, who had laboured with so much assiduity in the interests of the Company. Whenever he (the speaker) had called at the offices for information, Mr. Duncan had put before him very lucidly the points on which he had desired information.

Mr. CATER said he did not know whether the shareholders had noticed that heavy rains had fallen in Australia. He should think that that would greatly benefit the colony, and give a better tone to business there.

The proceedings then terminated.

Edison's Indian and Colonial Electric Company (Limited).

An extraordinary general meeting of the members of this Company was held at the offices, 4, Lothbury, last Monday, under the presidency of Major S. Flood Page, when the following resolutions, which were passed at the extraordinary general meeting of the members of the Company held on the 11th ult., were submitted for confirmation as special resolutions, viz. :—

1. "That it is expedient to effect an amalgamation of this Company with the Australasian Electric Light, Power, and Storage Company (Limited), and that with a view thereto this Company be wound up voluntarily."

2. "That Samuel Flood Page and James Drayson Austen Norris be and they are hereby appointed liquidators of the Company for the purpose of winding up its affairs and distributing the property"

3. "That the remuneration of the liquidators be £210, to be divided between them in such proportions as they shall think fit."

4. "That the Company do hereby approve and ratify the Conditional Agreement, dated the 20th day of May, 1886, made between the Company of the first part, Thomas Alva Edison of the second part, and the Australasian Electric Light, Power, and Storage Company (Limited), of the third part, which has been submitted to this meeting, and that the liquidators be and they are hereby authorised to adopt the said agreement, and carry the same into effect, with or without modification as may be mutually agreed upon."

5. "That the fully paid ordinary and deferred shares respectively of the Australasian Electric Light, Power, and Storage Company (Limited), coming to the hands of the liquidators, under the provisions of the said Conditional Agreement, shall be applicable in the winding up of this Company for the purpose of distribution amongst the members thereof, ratably in proportion to the number of their fully paid 'A' shares in this Company, one of the said fully paid ordinary shares, and one of the said fully paid deferred shares of the Australasian Electric Light, Power, and Storage Company (Limited) being given in exchange for one fully paid 'A' share of this Company."

The SECRETARY (Mr. J. D. A. Norris) read the notice convening the meeting as above.

The CHAIRMAN proposed the confirmation of the resolutions, and in the course of his remarks stated that all the shareholders of the Company, except one—who was not in England, and who could not be got at—had expressed cordial approval of the arrangement. Lord Tweeddale had also been good enough, at some inconvenience, to attend the meeting that day, in order to show his approval of it. He himself felt that there was some hope of their being able to do some business in Australia under the new order of things. He then read the resolutions, as above.

In answer to Mr. MOUNT,

The CHAIRMAN explained what was done at the last meeting. He stated, in further reply, that since Mr. Verity's letter was written, Lord Tweeddale and Sir V. Barrington had seen Mr. Verity, who had stated that he would not have issued the letter if he had known what he had been told afterwards. Mr. Verity also withdrew the letter.

Lord TWEEDDALE supported the statement regarding Mr. Verity's withdrawal of his opposition to the arrangement. He believed that Mr. Verity was entirely satisfied. Personally, he congratulated the shareholders and the Directors on having brought the arrangement to a head, and he believed there would now be a good prospect for the Company.

The resolutions were seconded and confirmed.

On the motion of Lord TWEEDDALE, seconded by Mr. PURMAN, a vote of thanks was passed to the Chairman, and the proceedings then terminated.

United Telephone Company (Limited).

Report of the Directors for the year ending 30th April last, to be presented to the shareholders at the sixth annual ordinary general meeting of the Company to be held at the City Terminus Hotel, Cannon-street, London, on Tuesday, the 6th inst., at 2 o'clock p.m. A reference to the capital account will show that up to the 30th April, 1886, the sum of £186,666. 14s. has been expended upon the works in connection with the metropolitan district and instruments on royalty in the metropolitan district and subsidiary companies, being £25,799. 18s. 8d. more than the outlay shown in the last balance-sheet. The revenue accounts show that the receipts of the Company from all sources properly attributable to the year have been £122,283. 15s. 1d., as against £103,000. 8s. 4d. in the preceding year, or an increase of £19,283. 6s. 9d., and the expenditure has been £54,681. 6s. 1d., as against £46,408. 6s. 1d., or an increase of £8,273. The working expenses for the year in the metropolitan district have been £32,548. 4s. 8d., as against £30,172. 19s. 7d. for the preceding year, or an increase of £2,375. 5s. 1d. The balance of net revenue account is £70,276. 17s. 3d., of which amount the sum of £17,711. 19s. 7d. has been absorbed by the payment of an interim dividend at the rate of 8 per cent. per annum for the first half year ending 31st October, 1885, and the directors recommend a further dividend of 9s. per fully paid £5 share (part paid shares receiving in proportion) for the second half year ending 30th April, 1886, amounting to £40,279. 19s., making a total dividend of 13 per cent. for the year. The directors also propose to carry £10,000 to reserve, leaving a balance of £2,284. 18s. 8d. to be carried forward. A sum of £2,753. 9s. 11d., representing profits derived from exceptional sources, has been carried direct to the reserve fund, in addition to the amount set aside for depreciation. The directors have, subject to confirmation by the shareholders, elected Mr. E. Dwyer Gray, M.P., to a seat on the Board. The shareholders will be asked at the general meeting to confirm the appointment. Mr. Dillwyn Parrish and Mr. W. Cuthbert Quilter, M.P., retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Quilter, Ball, and Co., and Messrs. Price, Waterhouse, and Co., also retire.

BUSINESS NOTICE.—Messrs. Henry F. Joel and Co. have removed from Tower-chambers to more commodious premises at 31, Wilson-street, Finsbury, where they will carry on the business of manufacturers of electric light apparatus and contractors.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 2nd inst. amounted to £2,889.

GUNMETAL VERSUS IRON WIRES.—The French Minister of Posts and Telegraphs has ordered gunmetal wires to be substituted for iron on some telegraph lines.

ELECTRIC SIGNAL BALLOONS.—Mr. Eric Bruce's balloons, with incandescent lamp inside, for military signalling at night, are to be tried by the French Government.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts for the month of June were £1,513, against £1,343 in the corresponding period of last year.

LONG DISTANCE TELEPHONY IN AUSTRIA. — Telephonic communication has been effected between Vienna and Brünn, a distance of 150 kilometres, or about 100 miles.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June amounted to £45,100, and to £41,514 in the corresponding period of 1885.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June amounted to £38,894, and to £37,846 in the corresponding period of 1885, showing an increase of £1,048.

MR. GORDON'S TREATISE ON ELECTRIC LIGHTING.—We are informed that Messrs. Gauthier, Villans and Co., of Paris, are bringing out a French translation of Mr. Gordon's book on electric lighting.

ELECTRICITY IN SCHOOL.—The subject of the theme set the pupils of the Ecole Centrale for the end of the scholastic year is "The utilisation of a waterfall, equal to 300 h.-p., for the public and private lighting of a town."

COLONIAL TELEGRAPHS.—To-day a paper will be read at the Indian and Colonial Exhibition, on the subject of Colonial Telegraphs, by Mr. James Sivewright, C.M.G., a report of which will appear in our next week's number.

LIGHTING IN PARIS.—The new Military Club, at the corner of the Place de l'Opéra and the Avenue de l'Opéra, which was lighted, at its opening, by Edison lamps, maintained by storage batteries, is to be permanently lighted by electricity.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 2nd July, were £2,266, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

GREAT NORTHERN TELEGRAPH COMPANY.—The receipts of this company in June were £23,600, and the receipts for the period of January to the 30th June, £124,560; for the corresponding months in 1885 and 1884 to £142,840 and £129,520 respectively.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 30th June are £2,862, as compared with £2,895 in the corresponding period of 1885. The March receipts, estimated at £5,959, realised £6,193.

DOMESTIC ELECTRIC LIGHTING.—The Electrical Power Storage Company have successfully started an installation of the electric light at the residence of Mr. J. Goddard, of Leicester. A 3½-horse gas engine drives a 3 unit dynamo, the total number of lamps fixed being 85.

TRANSMISSION OF POWER.—The Marquis Luigi Fonti has conceived a new method for the transmission of power, consisting essentially of decomposing water by the current of a dynamo, driven by hydraulic power, and transmitting the gas by the conductor to gasometers at the receiving station.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of June was 3,376, estimated to produce £2,775, against 3,715 messages, producing £3,032 in the corresponding month of last year. The traffic receipts for the month of March, estimated at £3,300, realised £3,345.

THE TELEPHONE IN ITALY.—The Italian Government, recognising the necessity for bringing up the telephone service to the requirements of the country, has appointed a Commission, which met for the first time on 16th June, and decided to consult the Chamber of Commerce, the Municipalities, and the existing telephone *concessionnaires* in the kingdom.

BLACKBURN TOWN COUNCIL AND THE TELEPHONE.—At a recent meeting of the Blackburn Town Council a resolution was passed accepting the offer of the Lancashire and Cheshire Telephone Exchange Company (Limited), to connect the Bowland works with the local municipal exchange by telephone, at a rental of £65 per annum for a term of five years.

THE NON-DESTRUCTION OF FILAMENTS.—Messrs. Siemens Brothers have lately been making lamps filled with hydrogen, and they find that these lamps do not become sooty on the inner surface of the glass. Next to a filament which will remain incandescent in the open air an envelope which will remain clean and not of itself destroy the filament is a desideratum.

SCHOOL OF TELEGRAPHY.—We notice that some interest is being taken on the Continent in the method adopted in England for teaching what we may term applied electricity. An article has appeared in our Italian contemporary, *L'Elettricita*, describing the school in Princes-street, now under the management of Mr. W. Lant-Carpenter. This is, we believe, at once the oldest and the most flourishing of our private schools.

LIGHTING AT MONACO.—The lighting installation at the Ministry for War, Monaco, put down by Schuckert, of Nuremburg, comprises 600 Edison lamps of 16 candle-power, though only about 400 are likely to be required at the same time. The current is supplied by two compound Schuckert dynamos, one for a hundred and fifty and the other for two hundred and fifty 16-candle lamps, the respective speed being 780 and 670 revolutions per minute.

RATIONAL SPEAKING TUBES.—An improvement, suggested by the telephone, has been made in the old speaking tube, by introducing a fork or branch, one end of which receives the flexible tube carried to the ear, while the other terminates in a bell mouth for speaking into, thus preventing the necessity of transferring the end of the tube from mouth to ear, and *vice versâ*. This is called the Pontifex speaking tube, and it is made by the Electric Apparatus Company.

A FAR FETCHED IDEA.—The *New York Herald* gives prominence to a scheme of Mr. Cloudman for lighting the Atlantic ocean by ten stations, anchored in the bottom of the sea, along the European-American route. The ends to be served by this bold conception would be to make meteorological observations, to communicate with ships, to signal, to help distressed vessels, and to give storm warnings. Of course, the electric light would be employed, each station being provided with its characteristic light.

ELECTRIC LAUNCHES.—The Electrical Power Storage Company have recently completed another electric launch, which

Digitized by Google

was tested last Saturday on the Thames. It was arranged that the Duke of Bedford's launch should be run at the same time, and the two electric launches started from Kew Bridge up to Teddington, and thence back to Millwall, causing considerable sensation. The Duke and Duchess of Bedford and others were present at the trial, which was most successful throughout, and more than answered the expectation of the builders with regard to speed.

ELECTRICITY FOR THE HEALING ART.—The Electric Apparatus Company have brought out a new induction coil actuated by a bichromate battery, and self-contained in a small box; and also a new constant-current battery, with means for regulating the intensity of the current from one cell to another, so that the force is increased progressively without the patient perceiving it. Moreover, in no form of battery for cauterisation do the details appear to be so well worked out as in the Byng cautery battery taken up by this firm, because they found no other for the purpose that they could recommend.

AN ELECTRIC PROBLEM.—Has the question of the simple or consequent poles of dynamos been sufficiently considered and discussed? In the earliest form of electric generator simple poles were used, viz., one N, and the other S; but in the machines which prevail at the present day, the N and the S are each made by two or more coil magnets, resulting, of course, in consequent poles; that is, two making N and two S. In the first case there may be lines of force running to waste; in the second there may be eddy currents and lines of force contending with one another. Which is best?

RYDE ELECTRIC RAILWAY.—A few days since the annual meeting was held of the Ryde Pier Company, Isle of Wight, when the directors reported to their fellow shareholders that the Ryde Electric Railway had been completed and put into operation at an entire cost of £1,300. The experience so far acquired in regard to the new line is in every respect satisfactory, and the management stated that the increase of the traffic, and the small proportion borne by the working expenses to the gross receipts, justified them in congratulating the proprietors on the wisdom of their decision in adopting this mode of locomotion.

NEW WIRE TESTER.—A wire tester, specially designed by Mr. W. H. Bailey, has been constructed by Messrs. W. H. Bailey and Co., of the Albion Works, Salford, for the use of the South Australian Government Telegraph Department. The tensile strength of the wire is tested in an ingenious manner by means of a column of mercury, and when the wire breaks a back-pressure valve prevents the return of the mercury, so that the breaking strength of the wire is thus exactly indicated. There is also a diagram attachment used with the machine which indicates on metallic paper the elongation of the wire before the maximum breaking strain of the wire is reached. The arrangements of the machine are so simple that levers and springs are entirely dispensed with.

THE TELEPHONE IN FRANCE.—M. Granet, French Minister of Posts and Telegraphs, has formed a project for reorganising the telephone service of his country. According to the *Journal des Débats*, a company is to buy up, on account of the State, the lines temporarily conceded to the Societé Générale des Téléphones, which is to work for thirty-five years without any guarantee of interest, while it is to lay telephone lines wherever they are required. The yearly subscription is to be 400fr. (£16) for Paris, and 300fr. (£12) for the departments. The capital is to be 25,000,000fr., or £1,000,000, with power to raise three times the amount by debentures. At the expiration of the concession the lines will become the property of the State, which also reserves to itself 15 per cent. of the profits.

THE INDIAN TELEGRAPH DEPARTMENT.—A Government resolution, published in the Indian *Gazette* of June 26th, conveys the thanks of the Governor-General to the Telegraph Department, in connection with the advance into and the occupation of Upper Burmah; and it is a pleasure to note that appreciation is expressed of the excellent services rendered in circumstances of much difficulty and danger by this department. The Governor-General eulogises the ready devotion to duty displayed in cheerfully accepting the hardships and risks involved in operations with an army in the field. The foresight and ability displayed by the Director-General are specially mentioned, and the Governor-General in Council gives cordial thanks to Mr. Cappel, Director-General; Mr. Brooke, Director of Construction, and several other officers of the department.

"INDUSTRIES."—This is the title of a new paper, with central offices at Manchester. We believe the proprietors are going to make a bold bid to achieve the impossible. The late Lord Brougham went in strongly for a "little of everything," but he also added "everything of one thing." The new paper has, or is to have, a little of everything; but it is not to have a "speciality." A second weak feature is the giving of "prizes." Surely the best way to make a paper successful is to make it worth the purchase money. Adventitious aids of the "prize" character savour too much of *Tit Bits* and that class of literary work. The first number is well printed upon good paper, and contains some articles interesting to electricians. Of these we may mention one on the principles of "Secondary Battery Construction," and another on "Telegraphy in Japan."

A YANKEE DODGE EXPOSED.—A report comes from Boston that a gross telegraphic swindle has just been exposed. It appears that a certain syndicate, calling itself "The American Telegraphic Company," of 90, Washington-street, advertised situations to young men and women, in which from 45 to 125 dollars a month could be earned. Of course, like all similar advertising frauds the applicants had to pay so much in advance. A large number who had paid from 10 to 45 dollars, finding that there was no prospect of getting the promised situation, but were kept in suspense for weeks, combined and caused the head of the concern—one Hellehan—to be arrested for obtaining money under false pretences. It is not yet ascertained what punishment has been meted out to this enterprising gentleman, but it is to be hoped that both he and his confederates will receive a smart sentence.

ELECTRIC LIGHTING AS AN INVESTMENT.—With a view to put at rest the question whether electric lighting constitutes a profitable investment, the *Scientific American* lately addressed a circular to the general managers of a number of such companies, asking for their experience, especially directing their inquiries to those adopting the Thomson-Houston system. The general tenor of the replies is that many of the local companies are earning better dividends than are yielded by the majority of other new enterprises, the question of profit resting first with the locality and then with the system employed and the ability displayed in the management. The highest returns came from Omaha, Nebraska, where a company, operating four 30-light dynamos, had earned at the end of the first three months after incorporation 4½ per cent. on the investment, or at the rate of 18 per cent. per annum; and two more dynamos of the same capacity have since been added to their plant.

LIGHTING AT THE COLINDERIES.—The four 50-unit Elwell-Parker dynamos, driven by two compound Galloway engines,

Digitized by Google

each giving out 80 horse-power on the brake, maintain 11,800 incandescent lamps, chiefly Swan, for the most part of 5 candle-power, but including some of 10 and 20 candles. Though these lamps might be maintained by three dynamos only, all four are used, and there is no duplication, nor any storage batteries; yet there has been no failure or hitch of any kind. The Pilsen, Crompton, and Brush arc lamps, maintained by their respective dynamos, driven by the Davey-Paxman engines, already illustrated and described in *The Electrician*, have spare machines to fall back upon; but there is no general duplication. Yet there has been no extinction, and no serious mishap or accident, for the men, under the superintendence of Mr. Schultz, are all trained to their work, and have been engaged on it for two or three years. The happiest effect is produced by small red and green incandescent lamps hidden in the vases of flowering plants.

Silvering Glass.—The incidental remarks in popular books often tend to show the wide applicability of an art, and to indicate directions in which students of pure and applied science may work with advantage. How many of those who study electricity realise the precautions that have to be taken in various industries against its action? In some cases it is turned to good use, in others it proves a trouble. In the "Pictorial History of Lancashire," p. 98, is a short popular description of a method for silvering glass, wherein is the following reference to electricity:—"So long as the amalgam is in an imperfect state, portions of it are liable to be detached from it by any electrical charges in the atmosphere or violent concussions of the air, such as a thunderstorm, a very high wind, or the firing of artillery." An accident so caused means generally the doing of the whole work over again. It would be interesting to know if any attempt had ever been made to utilise electricity to aid in the silvering or tinning of glass, instead of considering it in the light of something to be avoided.

Chesterfield and Midland Counties Institution of Engineers.—At the annual general meeting of the members of this institution, held in Chesterfield on Saturday week, Mr. G. E. Smith, electrician, Nottingham, exhibited a patent safety electric miners' lamp, weighing 7lb., and said by Mr. Schanschieff, the inventor and patentee, to be capable of giving light continuously for seven hours. The light is an incandescent lamp of 3 candle-power. For the use of miners, and in other cases where necessary, the batteries are hermetically sealed. The peculiar simplicity of the ordinary cell extends to the hermetic cell also, which is recharged without any screwing or complicated manipulation, and in a very short space of time. The lamp exhibited had been carried about the workings in Annesley Colliery, where safety lamps were used, and was perfectly safe in gas. In answer to inquiry, Mr. Smith said the makers asked £2. 10s. for the lamp, but he thought the price would be brought down to half that amount. The fluid was 2s. per gallon, and the cost of each recharging of the lamp would be 6d.

Thermo-Electric Couples.—An abstract of a paper by G. H. Le Chatelier appears in the current number of the Chemical Society's *Journal* as follows:—Avenarius and Tait have shown that the electromotive force of a metallic couple increases between 0° and 400°, in accordance with a parabolic function of the absolute temperatures of the two junctions, $E = A(T_1 - T_0) + B(T_1^2 - T_0^2)$, or if one of the two junctions is kept in melting ice, $E = at + bt^2$, where t is the ordinary temperature of the warm junction, and a and b are constants depending on the nature of the couple. The author finds that this law holds good for temperatures above 400° up to a certain limit which depends on the nature of the couple, and beyond which the value of the coefficients suddenly changes, whilst the nature of the equation remains the same. Values of the coefficients for platinum and platinum-iridium at different temperatures are given in the original paper. The calculated results agree well with those actually obtained, and any divergencies may be attributed to the well-known irregularities of thermo-electric couples.

Testing Mercury Ores.—The *Journal de Pharmacie et de Chimie* gives two methods for testing mercury ores invented by Señor Luis de la Escosura, chief of the staff of the Spanish mines. The second and more simple of these is the following: The mineral, finely powdered, is placed in a platinum capsule in a mixture of water, hydrochloric acid and sulphite of ammonia. For a mineral with 10 per cent. of mercury the following proportions are adopted:—Mineral 200 grams, NCl. 10 c.c.m., water 90 c.c.m., sulphite 20 c.c.m., so that about 120 c.c.m. are obtained. These proportions ought to be modified according to the richness of the mineral. The platinum capsule is placed on a support, and a gold disc is plunged into it, soldered to a gold stalk which communicates with the zinc pole of a battery of a few elements. The capsule is connected with the other pole. At the end of twenty-four hours the operation is ended, the mercury precipitates itself on to the gold disc, the increase in the weight of which indicates the richness of the mineral. This simple process is, it appears, of rigorous exactness even for very poor ores containing less than one per cent. of mercury. The impurities which usually accompany mercury minerals do not interfere with the operation. This process, which has been employed at Almaden for about a year, has been found superior to all others.

Combination of Cadmium and Iodine.—Mr. A. P. Laurie, in a paper before the Chemical Society on "The Electromotive Forces developed during the combination of Cadmium and Iodine in Presence of Water," says he has determined, by means of a Thomson electrometer, the electromotive forces of cells consisting of a cadmium and a platinum plate immersed in a solution of cadmium iodide containing free iodine. In one set of experiments, the amount of cadmium iodide in solution was constant and the amount of iodine was varied; in another the amount of cadmium iodide varied, the solution being in each case saturated with iodine; in a third, a constant amount of iodine, but varying amounts of cadmium iodide, were used. The result of the experiments is to show that, if cadmium and water containing cadmium iodide and free iodine are brought together, a considerable electromotive force is developed, which steadily falls. This depends on the facts (1) that as the free iodine is diminished, the electromotive force falls gradually at first, but more rapidly the less iodine there is present; (2) that as the cadmium iodide solution increases in strength, the electromotive force falls very rapidly while very small quantities of the salt are present, but more and more slowly as the amount of salt present becomes considerable. In both cases the change may be represented by a continuous curve. The actual values are given in the paper.

Pressure on the Resistance of Electrolytes.—According to the Chemical Society's *Journal*, M. Fink, in a paper on the influence of pressure on the resistance of electrolytes, concludes: "That the researches of Colladon and Sturm, and of Herring have shown that the resistance of electrolytes is practically unaltered by increase of pressure, whilst the more recent experiments of Lenz indicate a decrease of 0·02 per cent. in resistance for every increase of one atmosphere pressure, a result which would be a probable deduction from the experiments of Röntgen and Warburg on the influence of

Digitized by Google

pressure on the specific viscosity of liquids. The results are here given of experiments with solutions of hydrochloric acid, sodium chloride, and zinc sulphate, of various degrees of concentration, compressed at various pressures up to 500 atmospheres by means of a Cailletet pump. The apparatus is described in detail. The principal results are as follows :—(i) The resistances of the above electrolytes decrease proportionally with the increase of pressure up to 300 atmospheres; at higher pressures the relative increase is somewhat diminished, although it is allowed that this result may be due to errors in the manometer; the numerical results are practically in accordance with those of Lenz, although they are somewhat modified by changes in other conditions, such as temperature, concentration of solution, and nature of the substance dissolved. (ii) It is shown by application of the formula $p=\frac{\Delta v}{\mu}$, in which p is the pressure and μ the coefficient of compressibility of a solution, that the change of resistance in a liquid by warming under atmospheric pressure is not conditioned by change of density, but by increase of molecular mobility."

TELEMAREGRAPHS.—The abstract of a paper by J. Troost, given in the Inst. of Civil Engineers' *Journal*, says that fifteen stations have been fitted up for tidal observations along the Scheldt and its tributaries, between Ghent and Lillo, and connected with a central registering station by four telegraphic wires. Each station is provided with a tidal indicator and an observer. The tidal indicator has a pulley, which is turned by the movement of a counterpoise float suspended from a cord wound round the pulley. A pinion on the axle of the pulley works in a segmental ratchet, turning on another axle, and thus imparts to it the motion of the float. The ratchet sector carries a pointer, turning on the same axle, and whose extremity travels along a concentric scale, and indicates the position of the float above a given datum. Another smaller sector is fastened on the same axle, and its motion is accordingly proportional to the motion of the float. This sector is in contact with the observer, and by aid of this ingenious apparatus, which is fully described in the article, it is enabled to transmit an electric current to the central station during a period proportionate to the distance it has turned from its initial position. The duration of the current, and consequently the height of the tide at the given time, is recorded at the registering station by a graver marking a horizontal line along a zinc plate on a vertical revolving cylinder. The graver is pressed against the plate during the passage of the current; and consequently the length of the line graven on the plate is proportionate to the height of the tide at the time. The observations are transmitted at intervals of five or ten minutes; and the graver descends a slight distance after each record, so that a series of equidistant parallel lines are marked on the plate, forming the ordinates of the tidal curve for the particular station. The records of four stations are successively registered by one instrument on the same plate, the greatest length of any line being less than a quarter of the circumference of the recording cylinder. If the variations in level were considerably less, one registering instrument would suffice for several stations. Copies of the records are printed off from the zinc plates.

PROVISIONAL ORDERS.—We have already dealt with the Chelsea provisional order, but a little more information is given in the following from *The Times* :—"A parliamentary return has been issued showing the applications to, and proceedings of the Board of Trade under the Electric Lighting Act, 1882. Applications for provisional orders were received by the Board of Trade on or before the 21st of December from the Chelsea Electricity Supply Company (Limited), and the West London Electric Lighting Company (Limited). The first of these orders was granted by the Board of Trade, and a Bill to confirm it was introduced into the House of Commons on the 11th of June, and will be proceeded with in the next session. In the second order the undertakers, besides the extension of area scheduled, sought power to extend for a period of one year the time within which the compulsory works were to be completed. This order was not proceeded with. Since the date of the last report a further extension of the time within which the deposit of capital should be made in the case of the Fulham District Electric Lighting Order, 1884, had been approved, but the period so extended expired on the 15th inst. Since the date of the last report the Board of Trade had received an application for a licence from the Dundalk Town Commissioners. This licence had been settled by the Board of Trade. The Board of Trade had also granted two licences, referred to in the last report—namely, one to the Dalton-in-Furness Local Board in respect of the district of the Board, and the other to Mr. J. E. Veale, in respect of the district of the St. Austell Local Board. After careful consideration, the Board of Trade had decided to insert in licences granted to local authorities provisions empowering the promoters, with the consent of the Board of Trade, to transfer all or any part of the powers, duties, and liabilities conferred or imposed upon them by the licence as to the whole or any part of the area comprised therein, to any other body or person, and provisions to this effect had been inserted in the Dundalk and the Dalton-in-Furness licences. In 1884 a licence was granted to the South-Eastern (Brush) Electric Light and Power Company (Limited) to light a specified area in the borough of Colchester. In August, 1885, the Company went into voluntary liquidation, but the Board of Trade had agreed to the transfer of the undertaking to the Colchester Electric Light and Power Company (Limited)."

TELEPHONY.—The following correspondence has appeared in *The Times* with regard to the recent decision discussed by us in our last week's issue. On July 6th Prof. S. P. Thompson writes: "In the columns of your Law Report of to day there occurs a most extraordinary instance of the evil tendency at present pervading the practice of even our highest Courts of warping or straining the language of a patent specification so as to make it read in some forced sense in favour of a patentee who is backed up by wealthy supporters. This evil tendency, which is deliberately fostered by eminent leading counsel and by a few professional experts, who lend themselves to this mode of securing a monopoly for the patentee, is rapidly bringing into discredit the administration of the patent laws. The present instance, which occurred in the Appeal Court in the case of the United Telephone Company *v.* Bassano, arose in the following way:—The defendants, who are a small provincial firm of telegraph engineers, had constructed a telephone transmitter in a manner which they honestly believed to be different, not only in design, principle, and mode of action, but even in the materials employed, from the transmitter invented by Edison, the American, whose patent is held by the plaintiff company. There had been some question whether the 'tension-regulator' or mechanism of the defendants' instrument was or was not substantially the same as that described in the Edison specification. Lord Justice Cotton, in giving judgment on this point, made the following statement:—'Edison had mentioned several sarts of tension-regulators, but in that which had been ultimately preferred there were fixed blocks and suspended pencils of carbon which acted by varying the tension according to the distance between the carbon

Digitized by Google

points.' That is a very clear statement of what the learned judge considered the defendants to have infringed. But now comes the extraordinary fact that not only is this passage not quoted from the Edison specification, but there is absolutely nothing in the Edison specification even to support it. 'Fixed blocks and suspended pencils of carbon,' 'distance between the carbon-points,' are not suggested and never were suggested by Edison. The words 'fixed blocks' and 'suspended pencils' are never mentioned by Edison. Nay, even the substance 'carbon' is never once named by Edison. The nearest approach to all this in the Edison document is tufts of silk fibre covered with plumbago, or with volatilised metals, and lamp-black contained within a case. That a High Court of Justice can be so influenced by eminent advocates as to be able to warp and strain tufts of metallised silk and cases full of lamp-black into 'fixed blocks and suspended pencils of carbon,' and then to add that 'it was not the duty of the Court to point out the exact particular of the construction to which the infringement was due,' is one of those things which would be incredible if it had not actually occurred yesterday. But can any one explain how or why it is that not only in suits about telephones, but in suits about gas-engines and electric lights, the same process of judicial warping of patents has gone on?" And in reply Mr. John Imray writes:—"Under the heading 'Judicial Warping of Patents' Prof. Silvanus P. Thompson, in a letter published in your issue of this date, alleges that judges and justices of appeal are misled by counsel and expert witnesses to such an extent that they quite misunderstand patent specifications, and consequently give unjust judgments. The learned professor does not think it necessary to mention that he has himself condescended to perform the part of an expert witness, but as he has happened to be on the wrong side, *hinc illæ lachrymæ*. In the case referred to by Prof. Thompson, that of Edison's telephone patent, a new invention of an important and fundamental character had to be dealt with by the judges. It was not, like most patented inventions, a mere improvement in constructive details or in specific arrangements or combinations; it was an altogether novel departure, which, coupled with Bell's great invention, has led to a system of communication marvellous as it is useful. In such a case judges who know their duty do not tie down the invention to the precise details given by the inventor; they look for the principle on which the invention is based, they ascertain what is the spirit and essence, the 'pith and marrow,' of the invention, and if they see that, notwithstanding variations of form, material, or arrangements of parts, some rival apparatus has in fact the 'pith and marrow' of the original, they justly pronounce that to be an infringement."

City and Guilds of London Technical College.—The *conversazione* of the students of this college was held on Friday last, when a numerous company of their friends and relatives were invited to examine the numerous objects of scientific interest in the institution, as well as to participate in the pleasures of what in polite circles is called an "at home." A visit to this admirable institution—one of the few educational establishments in this country formed on the German principle of inculcating instruction in the applied sciences by means of practical experiment—always repays the visitor, but on the occasion in question it was made doubly attractive by reason of the fact that in addition to the ordinary mechanical, physical, and chemical appliances belonging to the college there were a great many exhibits kindly lent for the evening by a number of firms in the City and elsewhere. Messrs. R. and J. Beck and Mr. Crouch sent some highly magnifying microscopes, which were provided with some interesting object of the vegetable, the animal, or the mineral kingdom. Under each of these an incandescent lamp was placed, so that the guests might get a glimpse of a few of those wonders of creation which can only be revealed by these means. Mr. E. Cetti contributed a valuable collection of physical apparatus. The industries of soap and candle making were worthily represented by Messrs. Paton and Charles, John Knight, J. and C. Field, E. Cork and Co., each of whom sent a pretty case of their several specialities exhibiting the various stages of their manufacture. Messrs. Hopkins and Williams, Townsend and Mercer, Gaskill Deacon and Co., of Lancashire, Bevington, of Bermondsey, Pontifex and Wood, the Broxburn Oil Company, and Mr. Whitebread, of Chiswell-street, sent exhibits relating to chemical manufactures, with special reference to alkali, brewing, tanning, &c.; whilst the Express Dairy Company had a case showing the constituent elements of milk, &c. Electricity was represented by Messrs. Woodhouse and Rawson and the Electric Apparatus Company, who loaned a valuable assortment of their electrical appliances. But in this branch of science the college itself is for such an institution unusually well endowed. Indeed, it would be difficult to name an educational institute in or out of the United Kingdom where better means are provided for a thorough technical training in electrical science than the City and Guilds College, more especially in view of the fact that it has as its principal so eminent an authority as Prof. Silvanus Thompson. The weary student of text-books might well be excused for heaving a sigh of enviable regret as he walked through its spacious rooms, so fully equipped with all the requisite apparatus for gaining practically the knowledge which he is painfully labouring to acquire by the midnight oil. No better testimony to the advantages of technical education could be afforded than this section of the college presents. The whole of the building is lighted by incandescent and arc lamps of a variety of types, the currents being supplied by five dynamos of the Edison, Gramme, Victoria, Brush, and Phœnix designs. On Friday evening, it is unnecessary to say that, as on previous occasions of the same kind, the college put on something more than its everyday aspect. All the staircases and rooms were profusely decorated with flowers and bunting, some pretty effects in the former being produced in the water fountains by means of coloured glass and incandescent lamps. Amongst the more serious part of the night's proceedings was a lecture delivered by Prof. Thompson on the theory of the waves of light and polarised light. The lecturer, with the assistance of Mr. Kockburn, gave numerous illustrations of his subject by the electric light and the analyser. It is superfluous to add that the wonderful and beautiful alternations of colour thus displayed of that mysterious something which, in the words of the lecturer, "scientific men have agreed, for want of a better name, to call the ether of space," excited the greatest admiration and drew forth repeated rounds of applause. To this succeeded a short lecture on the nature and the component elements of the different classes of explosives, by Mr. John Castell-Evans, which was also very interesting. Whilst these gentlemen were discoursing learnedly on their different themes, a concert was being given in an adjoining chamber by the college choir, assisted by Miss Dickinson, Mrs. Montague Burnett, Mr. Aspinall, and Mr. F. M. Smith. Not the least interesting feature in connection with this part of the programme was the arrangement of a number of telephones by which the guests could hear the singing in a separate part of the building. In conclusion, we have only to add a word of congratulation to the students on the success which attended their painstaking efforts to provide for the comfort and entertainment of their guests.

TELEGRAPH REFORM.

On Tuesday morning a Congress of the Chambers of Commerce of the British Empire was opened in the Indian and Colonial Exhibition. The President of the London Chamber of Commerce (Mr. J. H. Tritton) occupied the chair. Amongst the subjects that came up for consideration was that of postal and telegraphic reform. The Congress lasted for two days.

SIR JAMES ANDERSON read the following paper:

The London Chamber of Commerce having requested me to prepare a short paper upon Telegraphic Reform, for the purpose of opening a discussion at the present Congress, I have endeavoured, in the following observations, to comply with their request, taking the four points specified in their letter, viz. :—

1. Reduction of Rates,
2. Extension of System,
3. Government Supervision,
4. Neutralisation of Cables,

as those which appear to the Committee most deserving of consideration.

It will probably be found that if a satisfactory solution of the first point can be arranged, all the other points will naturally adjust themselves.

It is not claimed in this paper that any of the methods advanced as illustrations of what can be done are specially recommended, nor has the sanction of any of the Submarine Telegraph Companies been obtained for putting them forward as representing their views.

They are given with the object and hope that discussion may develop sooner or later some plan for reducing tariffs which will be satisfactory to the public, and not ruinous to the shareholders, who have risked so much capital to establish the existing system of submarine telegraphy, which has already united all the commercial points of the world.

As a first illustration of what could be done to meet all the four points referred to, and dealing only with round figures, the following statement is made:—

The capital invested in this enterprise up to date is about		£35,000,000
The total revenue is	3,250,000	
Expenses, including cost of repairs, about 35 per cent.	1,137,500	
Net revenue	2,112,500	
Deduct 2 per cent. upon the capital for reserve and renewals	700,000	
	1,412,500	
Guaranteed interest of 4 per cent. on the capital	1,400,000	
		12,500

The present reserve of all the companies is about 10 per cent. on the capital.

If, then, 4 per cent. were guaranteed by the states and colonies specially interested, it would be in their power to adjust tariffs so as to reduce those which seemed too high, and to raise those which are too low, so that no loss need accrue to the guaranteeing powers.

But the cry would no doubt be for further reductions, and it is easy to estimate that if all the tariffs which are considered high were reduced by one-half, and those which are at present ruinously low doubled, the amount required to make up the 4 per cent. would not much exceed £1,000,000 per annum to be divided amongst all the guaranteeing states.

Reducing the tariff as suggested would certainly give a substantial impulse to the development of telegraphy, and this would no doubt be followed by still further reductions, and the enormous increase of traffic which would result would in a few years provide a surplus for extensions which cannot now be carried out without state or colonial subsidies.

Several reasons readily suggest themselves which would justify Governments giving this guarantee, and running the risk of large reductions

Moderate reductions of tariff never give any great impulse to traffic, and private companies cannot incur the certain loss which reductions always involve otherwise than with extreme caution, and very gradually. It takes a considerable length of time to recoup such losses, and it may easily follow that by the time the revenue has recovered its former amount, opposition cables may be laid with the ultimate result of a combination to raise the tariffs to a point that will save the companies, with their unnecessary cables, from financial ruin.

If the states guaranteeing the 4 per cent. dividend were bold enough to reduce the tariff to a point below which it would not be necessary to go for many years, the enormous increase of traffic which would be developed would largely augment the growth of internal correspondence both by telegraph and post.

It would stimulate commercial activity, multiply transactions, and generally increase the wealth of the nations. Private companies cannot gain directly by these factors, but Governments gain in every particular, and gain at once.

Government can also effect economies by unity of management, absence of needless competition, and uniformity of an international system.

There is probably no system of inter-communication between nations so uniform as telegraphy—that is, the exchange of messages between two countries is, as a rule, about equal, and where this is not exactly the case, sufficient data exists to establish the respective proportions. So that the nations of the world could agree to deal with their receipts according to these proportions without rendering accounts.

This alone would effect a substantial economy, and is already done by a number of Continental states, and in my opinion it is in this direction and in that of low and uniform tariffs that we are progressing.

Another plan would be that, in consideration of a monopoly, Governments should regulate the tariffs, requiring a reserve for maintenance and renewals, and all excess of revenue over a given dividend to go in reduction of tariffs; but as there are companies which earn no dividend, this plan cannot be made so generally applicable, and I believe the experience with water and gas company monopolies has not made this system a favourite one.

Third Plan.—Germany, in the case of one company, has guaranteed a certain amount per annum, with the condition that a sum equal to 1 per cent. per annum of the capital be set aside for amortisation, and 10 per cent. of the revenue for repairs and maintenance, so that at the end of a given period the cable, together with the reserve, becomes the property of the Government.

They also retain the right to purchase at par any of the stock not cancelled by amortisation.

Fourth Plan, and this is a favourite proposition of Mr. Pender, the Chairman of the Eastern Telegraph Companies, who is absent upon his political contest. The Australian colonies at the present time have under consideration a proposal to guarantee to the Eastern Company and its partners and to the Eastern Extension Company the average revenue derived from Australian traffic over the last three years, and they may then reduce the tariff to what they please, subject to out payments to other Government administrations.

The colonies would thus take the risk of the increase, and if they are satisfied, as it is reasonable they should be, that a low tariff will give a great impulse to the traffic, then the amount payable under the guarantee will be comparatively small, and in any case the gain to the colonies commercially cannot fail to be very great. All the calculations on this point are now before the colonies interested. This plan is probably the simplest of all, requiring a minimum of negotiation, with the additional advantages of being immediately applicable and capable of being discontinued after an agreed period if found to be unsatisfactory. If adopted, it would probably, sooner than any other plan, lead to the adoption of a more general and extended international scheme.

It is obvious private companies cannot make sacrifices involving certain great loss, or if they must do so from undue competition, the benefit to the public will only be fitful, as either the companies must combine to raise the tariff or

Digitized by Google

capital will avoid a class of property so uncertain in its durability, and unsafe owing to needless and ruinous rivalry.

Telegraph Reform.

Two or three sentences only need be devoted to this point.

The commercial public should be warned that, sooner or later, the present abuse of the code system will be stopped to the great inconvenience of those firms who are building up a huge mass of made-up words, syllabic combinations having the appearance of words only, and unknown to any language. This practice, which is growing, is *unfair*, if not illegal, and contrary to the convention by which all telegraph administrations are bound, and will some day have an abrupt ending, especially if ever there is Government control of any kind.

The system of coding really enables merchants to send on an average about ten words in one. The formidable-looking tariffs are, therefore, not so extreme as they appear, and the companies think they should be fairly dealt with.

As the general result of the last ten years' working with India, we are carrying four times the number of telegrams and making 44 per cent. more money; but one-third of this increase of revenue is due to other causes than the number of commercial messages.

We do not make any objection to a free use of all words not exceeding ten letters in the eight authorised languages, which provide at least 100,000 fairly good telegraph words, each word differing by two letters, and each of these 100,000 words can be arranged to express five different references, such as quantity, quality, freight, price, and time, as to any article which merchants are accustomed to deal in.

The system of manufactured words which some firms are persistently trying to force upon us enables merchants to tabulate a million of words, with practically unlimited power of expansion. This in time may drive us to a high single letter tariff, an authorised code or rigid restriction to what is meant by eight languages, and the attention of the companies has quite recently been authoritatively called to their duty of strictly observing the Convention rules.

The foregoing remarks contain, I think, plans by which reduction of rates and extension of the telegraph system can be provided out of revenue, and Government supervision will naturally be claimed by the guaranteeing states.

Neutralisation of Cables.

I now come to the question of the neutralisation of cables, what promoters of other submarine lines like to call alternate cables for a time of war.

To my mind this is not the main object for which submarine cables should be laid. There is a growing federation of commerce in which all nations are already free to share.

For all nations the "foreign trade of the world has become an extended home trade," and the two great factors which make the federation of our own race possible are steam and telegraphy.

These points have been already formulated by Mr. Crump, of *The Times*, and Prof. Seeley, of Oxford, and they will yet claim far more serious international attention than is now dreamt of.

As for submarine cables in time of war, it will be evident that if a number of Governments undertake to guarantee interest upon submarine cable property for the sake of controlling the tariffs, it will not be permissible for any one nation to damage or destroy them wilfully with impunity.

Already this question is becoming complicated. America, France, Germany, Italy, Spain, Greece, Turkey, Denmark, and England all own or have a direct pecuniary interest in cables.

Some of the most important of these Powers are making sacrifices and great efforts to extend their colonial system. Cable communication is indispensable to the government and defence of these colonies—to Great Britain and her colonies supremely so—and to all of them, as well as to every other country commercially, it is of the utmost value nowadays to have all parts of the earth in telegraphic communication, so that belligerents may by-and-bye be taught that they must fight their quarrels out without destroying the means of international intercourse which are indispensable to the commerce of those nations not concerned in the quarrel, and who are strong enough to make their wish not to be cut off from the commercial world respected.

All that, however, is only so far so good. The greatest deterrent to the destruction of telegraph cables in time of war will be the knowledge that there are so many routes by which a message can be sent with only a moderate delay that the breaking of a cable would not really affect a campaign or a single battle, and it would not therefore be worth while to destroy cables.

At present there are exceptions where this condition of various routes does not exist, and where it would not pay commercially to create more lines, but in the event of war in which Great Britain, for instance, might be involved, about three or four months would suffice for strategical cables to be laid to secure all the telegrapic communication necessary for a campaign in any given part of the world. Ten thousand miles of cable could be made and shipped in four months.

It should not be forgotten that prior to the outbreak of any war the cables which exist suffice for the arrangement of fleets and armies.

It is altogether improbable that all the cables would be destroyed before war was declared, then, in that event, with the foresight we have a right to expect, the fleet, despatch boats, armed cruisers, and colonial defences would be so arranged that, at all events, telegraphic communication should not be all we had to rely upon. *In any case, there is no alternative that can be suggested other than strategical cables to be laid when required.*

Until necessary such cables should not be laid. It would be a waste of money, and their position would be known, which need not be the case if they were not laid until they became indispensable.

The conditions which should govern the laying of all submarine cables, as far as they can possibly be observed, are the following :—

They should touch at as many points as are likely to develop traffic.

They should be laid in the track followed by the mercantile marine of the world, because, first, in the event of war the same cruisers which protected our commercial marine and our transports would so far protect the cables.

Second, if interrupted upon any section, the commercial steamers passing to and fro can bridge over the broken section by carrying telegrams; and one or more would be chartered for this purpose until repairs were effected; or gunboats could in time of war bridge over the short interrupted sections; and *there is no doubt that hereafter ships with telegraph cables will always follow the fleet*, with the object of connecting any point best calculated to insure uninterrupted communication with the base of operations or head-quarters. Cutting cables, therefore, in time of war is not so important as it looks.

Long cables of several thousands of miles should be avoided as far as possible. There are no commercial points of the first importance at the present time unsupplied with telegraphic communication.

Any extensions of long cables cannot be made to pay. They can be cut as easily as any other cable in time of war, and require much time and great expense to repair, *so that they afford no additional security as alternate routes in case of war.* It would be better to employ the subsidy necessary to the existence of such cables in increasing the number of shorter sections where desired, touching at the commercial ports of the world; and in reduction of tariffs.

Fourteen years ago when I read a paper upon this subject the whole capital of the submarine cable companies was £10,000,000. It is now £35,000,000, and will probably ere long be £45,000,000, so that all the time the Governments of the world postpone acquiring control of submarine cables the more difficult it will become, as nothing anyone may write or think will prevent promoters of this class of enterprise from pushing forward schemes for more cables upon one pretext or another. Especially if the Governments are prepared to delude themselves by supposing that long commercially-unremunerative cables can have anything to do with securing a permanent communication in time of war.

Digitized by Google

Strategical cables for war purposes are one thing. Binding all the ends of the earth and every commercial point of the globe for the purpose of promoting trade is quite another affair, infinitely more worthy the consideration of the representatives of the chambers of commerce here assembled.

I believe these observations embrace all the points necessary to open up a full discussion of the international value of telegraphy.

DISCUSSION.

The Marquess of TWEEDDALE then said :—Having been connected with the different submarine telegraph systems for many years past, I am very glad to have an opportunity of offering a few remarks on some of the subjects referred to in the paper which has just been read, a copy of which I have had the advantage of perusing. The first subject, namely, the reduction of rates, is the most interesting and the most important. Perhaps, at the outset, I may be allowed to point out that submarine telegraph cable rates differ in one essential point from postal and railway rates. A postal or railway rate is a fixed figure for so long as it remains unaltered by the authorities controlling the Post Office or the railway company. It cannot be evaded or modified by the public. This is not the case with submarine telegraph cable rates. When a submarine telegraph cable rate is fixed the code system comes into operation, and at once modifies the rate so fixed in a manner and to an extent which is not appreciated by the public. Sir James states in his paper that "the system of coding really enables a merchant" (and he might have added every individual) "to send on an average ten words for one paying word." Now, let me indicate what this means. It means that where a cable rate is fixed at, say, 9s. 4d. a word, the public, in fact, pay 11d. a word only. Nor has coding done its best, or shall I say its worst, in modifying rates. When Sir James first investigated this subject, he found that about seven words were sent for one paying word. This has been increased to ten, and there is every reason to suppose that the art of coding will be still further developed, so that more than even ten words will be sent for one paying word.

I may say, in passing, that I am not alluding to what Sir James describes as the unfair practice of using syllabic combinations in place of real words. It may be unfair, but it is impossible in practice to prevent it. My remarks apply to legitimate coding. I have shown that by coding the rate to Australia, though nominally 9s. 4d. a word, is reduced in practice to 11d. a word only. Now, let me point out what this rate comes to per 100 miles, and how it compares per 100 miles with land rates. Australia is 11,499 miles from our shores. The codification rate per word being 11d., the rate per 100 miles is ·094 on the actual rate, or ·94 of a 1d. on the published rate—*i.e.*, 9s. 4d. a word. The telegraph rate in Great Britain is ½d. a word, with a minimum of 6d. Taking 400 miles as the average distance traversed by a message in Great Britain, the rate per 100 miles is ·12, or half a farthing a word. Now, when it is borne in mind that a submarine telegraph cable costs five times as much as a land line, that its maintenance is infinitely more expensive, and that it is exposed to war risk, which must be provided for by a special fund, I think it will be admitted that the real rate at present in force between Great Britain and Australia is not only not an extravagant one, but is, in fact, a very reasonable one.

Another point to be borne in mind in discussing submarine telegraph rates is that the conditions and circumstances are not the same in respect to cables laid to the West or to America and to those laid to the East. In the former case there is no land competition possible. No monopoly (except in respect to landing at Newfoundland) is possible. In the latter case there is competition by land lines for a great part of the way to East Australia and China. And if there is no distinct monopoly, there is a quasi monopoly which cannot be overlooked. In the Atlantic the question of rates—*i.e*, the rate which is ultimately to prevail—is still an open one, and can and will only be decided by the operation of competition. Several rates have been tried, a 2s., a 1s. 8d., a 1s., and now the rate is at sixpence a word — reduced by coding to less than a penny a word. This rate has been in operation for a few weeks only. The increase has been so far about 110 per cent. This is not an increase sufficient to constitute it a paying rate, but it is sufficient, I think, to encourage the cable companies to persevere with it, so that the rate may have a fair trial. If the rate is kept at sixpence a word for a year, or even two years, the question of the rate which is ultimately to prevail will receive, I trust, a final solution.

In the case of the submarine telegraphs to the East, the conditions, as I have stated, are not the same. The question of rates, more especially in the instance of Australia, cannot be settled by competition by parties unaided by governmental contributions. The present rates are, I believe, only fair and reasonable, and here I may say that I entirely concur with Sir James's remarks as to the little value of moderate reductions in stimulating traffic, and the impossibility of companies incurring the risk of loss attending large reductions. Take the reductions made in this country from 1s. to 6d. The Government is losing 2d. on every message. This state of things would render any company bankrupt in a short time. There appear to be in the case of Australia, at any rate, only two modes by which a further substantial reduction of rates can be effected. One is by the method referred to in this paper, that by which the Eastern Extension Telegraph Company shall be guaranteed the average revenue derived from the Australian traffic during the last three years, the Australian Government being at liberty to reduce the tariff rate to what they please. The other plan is to largely subsidise a cable or cables from Australia to, say, British Columbia. One of those cables that, to use Sir James's words, "promoters of rival submarine lines like to call alternate cables for a time of war."

It is not for me to offer an opinion as to which proposal is likely to find favour with our Australian fellow subjects; but I should wish to point out that nothing, in my humble judgment, could be more unwise than to spend a large sum of money annually in supporting a cable or cables which could not possibly pay in time of peace, and the exact position of which would be known to all the Powers in time of war. Sir James has pointed out with unanswerable force that a truly alternative line for use and protection in time of war—a line laid for strategic purposes—should not be laid until war is imminent. For in that way only could it be laid with some prospects of its position being concealed from an enemy.

Digitized by Google

On this subject of the protection of cables during a time of war I refer to the opinion of Admiral Sir Cooper Key, late First Sea Lord of the Admiralty. His opinion I understand to be that it will be idle to expect the Powers to agree to respect one particular class of private property, such as telegraph cables, rather than another during war. Consequently, the only way that we can hope to protect cables during war will be by means of swift armoured cruisers, which should be employed, not to convoy fleets of merchantmen, as of old, but to patrol the sea routes followed by merchantmen as well as by cables. It would be quite reasonable to expect the Admiralty to afford great if not complete protection to cables laid in the Red Sea between Aden and Bombay, between Madras and Singapore, and on to China and Australia, coinciding, as these routes do, with lines of commerce; but what protection could the Admiralty be expected to extend to a telegraph cable lying at the bottom of the sea for a distance of over eight thousand miles, altogether out of the way of the routes followed by merchant ships? The inference I should be inclined to draw from this reasoning is that if the Government of Australia are really anxious to bring about a large reduction of the telegraph rate, and are prepared to spend a considerable sum of money in rendering telegraphic communication not only more cheap but still more secure than it is, both in peace and in war, that money can be more usefully spent on the lines already existing than on cables to be laid in the Pacific, open to the serious objections of being laid at enormous depths and in long stretches.

In conclusion, I have only to say that I have not deemed it necessary to refer to that part of Sir James's paper which deals with the advantages likely to accrue from the submarine telegraph cables being taken over and transferred to the different Governments interested in them. It is an interesting matter for speculation, but scarcely within the range of practical politics. I will not occupy your time any longer, for I see more than one present able and, I hope, willing to take part in the discussion; but before sitting down I hope I may be allowed to express my regret at the absence of Mr. Pender, chairman of several telegraph companies, whose energy and success in promoting submarine telegraph enterprise is well known to many here present.

Mr. M'MILLAN (Chairman of Sydney Chamber of Commerce): Mr. Chairman and Gentlemen—We have two members of the meeting here connected directly with telegraphic work, Sir James Anderson and the Marquis of Tweeddale. This, of course, puts us to a certain extent in a somewhat delicate position, and I am sure that both Sir James Anderson and Lord Tweeddale will understand that in approaching this question, we must look at it from the point of view of our own interests. I think it may be considered an axiom that to further economy in the centre of the British Empire it is necessary to have greater telegraphic communication. Consequently, without meaning to emphasise my position as a representative from Australia, I think this matter of telegraphic communication is more urgent and of more moment in regard to Australia than any other part of the British Empire. I should like to clear away one misunderstanding in regard to one of the remarks in this paper of Sir James Anderson. I do not think that the movement in Australia towards having a separate cable was founded on any feeling inimical to those interests which already exist, but it was the result of what we could not help calling the very unneighbourly position taken up by the Indian Government. We found that the great drawback to the telegraphic system on our side was owing to the resistance of the Government to a reduction on the land lines, which we thought had been carried on by this country. Now, I had the honour to speak at a deputation where I interviewed the Postmaster-General of New South Wales, with regard to one of the schemes of Sir James Anderson's paper—that is to say, that the Australian colonies should make up any loss on any three previous years' working on the understanding that they would have the control of the rates. I may say that we have often suffered very much in the colonies from the want of a thoroughly commercial man at the head of the Post Office department. I am speaking now to commercial men, and while I do not wish to imply that a commercial man does not make as good a statesman as anyone else, yet I think if there is one department of the Government which requires a man of practical authority and business experience it is the postal department of the Government. This proposition was made, and I believe it received a great deal of favour at the hands of our Government, and steps were taken to get the other colonies of Australia to co-operate. I have another point to touch on, and that is the codification. I must say that I cannot myself see what limit could be put to the system of codification, and it would be very necessary, whatever may be the basis of future arrangements made, that if any arrangements were made between the Government and the colonies and the different telegraph lines, we should have a very clear understanding with regard to our position in this matter of codification. I may say that if there were stringent measures to narrow the codification it would practically do away with a great deal of the commercial use of the telegraphic communication a'together. You know the fact is, besides, that one of the greatest arguments for the reduction of charges is, in the first place, that by this codification you are liable to error, and, in the second place, as we all know, it unceasingly happens that, in order to avoid committing any errors, it is necessary to use the ordinary English language, and consequently this matter of cheap telegraphy is important from every point of view. I have no hesitation in saying that if the rates in Australia were reduced to a reasonable extent—if they were reduced to such an extent as to make the telegraphic code take the place of the ordinary letter or memorandum, so as to give us a chance of carrying out a large portion of our business operations through the telegraphic code—I was going to say if that reduction were made, I believe that so far as the Post Office Department is concerned the business would be doubled, if not quadrupled, so that, as a business transaction, they could not ultimately, as I urged upon our Government, lose upon it. I take it that we are met here to try and impress on the Government that it is of the utmost importance to thresh out this question.

Mr. J. K. BYTHELL, of the Bombay Chamber of Commerce, then said: Mr. Chairman and Gentlemen—I am sure that we are all greatly obliged to Sir James Anderson and the Marquis of Tweeddale for putting this question, from the companies' point of view, so clearly before us. When I got the list of subjects to be discussed at this conference I wrote to the Bombay Chambers of Commerce and asked them to give me their view on any question they wished me to refer to, and their opinion is that if the telegraph companies would make a reduction of 20 per cent., in their tariff it would be fully recouped by the increase of business that would assuredly follow that reduction. And in spite of the arguments laid before us by these two gentlemen, my own opinion is that if the companies did make a reduction, say of 20 per cent. in the rates to India, the revenue would soon be recouped by increased business. I agree with the last speaker in the remark he made that in spite of all our codes we are day by day obliged to telegraph literally to prevent mistakes. I may say as a matter of fact from my own experience, that we are very often deterred from communicating by telegraph simply because of the excessive cost. And I can speak from my personal experience, because the firm in which I am connected pay many thousands of pounds to the Eastern Company for telegraphy to India. With reference to the question of having a national guarantee, the question has come before us without any previous warning, and I do not feel that I am prepared to pass an opinion upon it. But I should like to take this opportunity of asking these gentlemen what they exactly mean by saying that some firms are having syllabic combinations of words which are unknown to any language. I thought that the rules of the last telegraph conference absolutely prohibited the making use of unknown words.

Sir JAMES ANDERSON said it was the abuse of consonant and vowel combinations making words unknown to any language that was complained of.

Mr. BYTHALL: We have only used Dr. Agar's books, which contain 150,000 words. We were not clever enough to do

Digitized by Google

what Sir James Anderson has suggested, and I do not think that others should be allowed to take advantage of those who keep to the regulation code (applause). At the same time, I believe that it will be necessary to allow mercantile men to have their codes. (Sir James Anderson: Certainly.) I am sure if we had not an elaborate code for telegraphing the cost would be prohibitory. These are the only two points to which I wished to draw special attention. It appears to me that there is not much need of making any international convention. I feel impressed with the argument that such a convention would not be acted up to in time of war, and that by the means to which Sir James Anderson referred it would be very easy to keep our telegraphic communications open, even in time of war.

Sir WILLIAM ADAMSON, Singapore: Mr. Chairman and Gentlemen—I did not intend to speak on this question. We must remember that the two eminent gentlemen—Sir James Anderson and the noble marquis—have spoken entirely from their point of view. They are both well known to be connected with telegraphic companies, and their ability has enabled them to put their side of the case before us with considerable clearness and power. Now, I was very much surprised at the prominence which Sir James Anderson gave to the code question. It seemed to me that it was a warning to some of us that they proposed to make a change. If Sir James remembers my name he will connect it with a firm which has always used fair means of codification with the company. I think we have never used any of those compound words, and I claim that we have been using codes, and we are one of his best customers. I maintain that the proper use of codes is absolutely necessary. I say distinctly that if it were attempted either by the companies that exist or by the Government—supposing they were to take up the lines—if it were attempted to do away with the codes the trade of the world would be interrupted to that extent that there would be a public outcry. I do not know whether it is known to all of you, but I may say—and I speak for Bombay—for an active business connected with the East Indies the cost of telegraphy is a charge of about 6s. 6d. per cent. on an operation. You gentlemen from Australia, who deal in large lines, such as in wool, and in matters which you can express in two or three words, do not appreciate the number of articles that are sent from India and from the far East. Is is quite a common practice to buy to-day in Calcutta, Bombay, and Singapore 25 tons of goods, which may come to £800 or £900, and to sell them to-morrow in the London market, and that has to bear the expense of four telegraph words, do it as cheaply as you can. If we were interfered with as to this subject of codes, it would be made the occasion of such an outcry that even the Eastern Extension Company would not be able to stand against it. Sir James Anderson told us, and made an important point of the fact, and I was astounded that it was a fact that some firms were in the habit of using compound words. I was very much surprised to hear this, because by the law that you have laid down we are limited to English, and to the four Latin tongues, and to German, to which I think was added Dutch. Therefore, I cannot understand how the companies should allow anyone to use such words, or if they do they injure men like myself who are dealing fairly with the company on their own system. There are two points to which I wish to draw attention. In the first place, Sir James put before us a statement that the total capital account of the telegraphic cables of the world was thirty-five millions, and then he went on to say that 4 per cent. on that would be so much. Now, 4 per cent. is not a large return for telegraphic property. That may be conceded at once. But I think we may draw a distinction between the amount of money which has been sunk on the Atlantic cables and the amount of money which has been spent on the cables which stretch from here to Australia, and I think if he separated these two, and told us how much had been spent on the Eastern cables, perhaps, then, he would find himself with the present traffic able to make a much larger return than 4 per cent, and put a very much larger amount to the renewal fund. You must also remember that since those cables were made an enormous economical improvement has come about in that direction. A cable to-day does not cost anything like what it did ten years ago, and, therefore, that capital already sunk in the cables of the world is not worth its first value.

Sir JAMES ANDERSON asked leave to explain that neither he nor any one else connected with telegraphy that he knew of had any desire to put down the use of codes. In fact, the Companies were the originators of code language, and his friend Mr. Weaver, whom he saw sitting in front of him, was the first to introduce the word tariff, so that merchants could send only one, two, or three words if they thought proper.

The discussion was adjourned.

The discussion was resumed on Wednesday morning by Major P. B. WALKER, Superintendent of the Telegraph System of New South Wales. He said: Mr. Chairman and Gentlemen—I am much obliged to the members of the conference for permitting an adjournment of the discussion on Sir James Anderson's paper upon telegraphic reform, as it embraces such broad principles that the consideration of the many points enlarged upon must prove of the greatest interest, not only to commercial people of Great Britain, but to all parts of the world. Sir James Anderson seems to think that a satisfactory solution of the question of reduction of rates would lead to a natural adjustment of the other three points of telegraphic reform specified in his paper, and no doubt it would materially assist matters, though I fail to see how it can possibly affect the question of Government supervision. That is a point which must be dealt with upon its merits, leading as it does to a question involving the deepest consideration owing to the numerous conflicting interests which are at stake where so many Governments would be interested. And we have had recently an instance of the difficulties surrounding this particular feature of the question in the matter of reduced rates to Australasia, adopted by the Berlin Conference, but delayed by the action of the Indian Government, thus showing that the difficulty in connection with Government supervision is great.

The telegraphic companies have done much to promote commerce, have greatly enlarged general progress throughout the world, and certainly they are entitled to the most favourable view of their interests that can be given, because without such aid we should never have been able to utter those well-known lines, that

> London speaks at twelve o'clock,
> Australia reads ere noon the shock.
> Seems it not a feat sublime,
> Intellect hath conquered time.

We must assume that it is only just that the cable companies should ask a fair interest as a guarantee if tariffs are demanded that do not accord with their expenditure sufficiently to enable them to submit fair returns to their shareholders, as all cable property is of a risky nature, and although the capitalist may for years receive his dividends regularly, he stands a risk that no other investor does, viz., the risk of storm and tempest, rendering himself liable to rise some morning to find his properties swept away. It therefore necessarily follows that the companies must look out to protect themselves. Nevertheless, when the general public find that a sum of £300,000 per annum is being paid on Australian traffic for international telegrams alone, it is considered a striking proof that a necessity exists for cheaper communication with other parts of the globe, and the colonists naturally look for more popular rates than those now conceded. The ruling passion of the modern age in commerce is for cheap telegrams, and in a young country like Australasia, where telegrams can be sent in some of the colonies for a penny a word, and in others at 1s. for ten words and one penny each extra word, it presses hard for the colonists to have to pay 10s. 10d. per word (including the local rates) to the United Kingdom. Nearly 29 years ago, when first I joined the telegraphic service in the colonies, the charges were as high as six shillings for the minimum local rate and 9s. the intercolonial minimum rate, but it was found necessary to meet the demands of commercial enterprise and progress by bringing the most popular means of communication by telegraph within range of all classes.

Sir James points out that it would be prudent and proper for the Governments to give a guarantee; but if it be admitted

Digitized by Google

(as pointed out by his paper) that reducing of the tariff, as suggested, would certainly give a substantial impulse to the development of telegraphy, and result in an enormous increase of traffic, I do not see why the companies do not in their own interests, and in the exercise of a commercial spirit, carry out these reductions. Experience has shown that other things have benefited financially, and made themselves popular institutions by adopting such a course, and perhaps the companies may yet see their way to assimilate their proposals to suit the public.

Sir James has suggested two ways of reducing the tariff, viz. :—

1. By a guarantee.
2. By a subsidy.

There is no doubt that a guarantee would be by far the best mode of dealing with the question asked, and leave the Governments interested free to deal with any further arrangements desirable for the public benefit by supplementing the means of communication, and although the traffic would be greatly augmented by a low tariff, still it would be necessary to regulate the guarantee upon the basis of the present traffic. I find that the traffic has for eleven years increased 40 per cent. per annum, and the last three years have shown a more moderate regular growth, which gives a sure basis for an estimate.

There is one other point in Sir James's paper having reference to the figures regarding the construction of cables which I cannot construe, owing to the absence of sufficient data. The cost is put down for expenses, including repairs, at 35 per cent., which appears to be a very heavy allowance, but I presume it is based on experience. The item of 2 per cent. for reserve and renewals also strikes me as heavy, especially as it can be reckoned that a reserve invested properly would recoup the principal in 20 years. Another reason which confirms my opinion that the proposed 2 per cent. for reserve and renewals is out of proportion to the necessities of the case is the fact that though the cables have been in existence for so long a time, the companies have only thought it necessary to make a reserve which at the present time aggregates 10 per cent. on the capital, and the company's judgment upon this point has been, I presume, borne out from the fact that they have hitherto sustained no serious loss.

Sir James Anderson points to the probability of codification messages being interfered with; but this would be a serious interference with the inter-exchange of mercantile as well as important Government and press messages. In addition to that, the companies themselves would suffer greatly, as although perhaps five or six words may be included in the code word, still it would lead to curtailment in the transmission of messages which, in the end, would cause a diminution in the traffic and loss to the companies. I would further remark that this system is also a great protection to the Governments and merchants in that it renders the secrecy of the messages inviolable. I know that difficulties have to be surmounted in dealing with this question, still the public convenience is one of the first principles of telegraphic reform, and to attempt to abolish the system of codification would be a retrograde step, disastrous alike to all classes of the community.

Sir JAMES ANDERSON, in reply, said: Mr. Chairman and Gentlemen—It would be very easy to prepare a paper to show that the Government save a great amount of money every year by having the use of the telegraphs in the matter of the concentration of our small forces in different parts of the world, and in the concentration of our fleet, as well as in moving them about from place to place. I have no doubt that is the great object they have in view when they talk of subsidies to the telegraph companies. It would, in fact, be easy to prove that they save much more money by the existing telegraphs than the amount that they give to us in subsidies. In my paper yesterday I tried to show that there were methods, if all the different countries of the world were combined, by which they could lower the tariffs very substantially. Major Walker just now says that if they admit that the traffic will grow largely they might very well show some public spirit and lower the tariff themselves. If, however, they were to lower the tariff, say, to 2s. to India and to 4s. to all other places beyond India, the companies would lose more than half their present revenue, and that would take possibly four or five years to recoup, and after that there would be no loss. But directors of companies are not allowed to take shareholders' money and run such risks. We are commercial companies, not philanthropists, and therefore you cannot expect us to do it. The loss of a million, however, divided amongst several Governments for two or three years, would be a very small loss indeed compared with the immense advantage of having cheap telegraphy. Probably no institution was ever devised more conducive to federation—just now so much talked about—than the making of telegraphy as cheap as possible to all parts of the world. I consider it is of far more importance than even cheap postage, because to be able to talk with the ends of the world in a few hours is a feature the vast importance and value of which has not yet been realised, and I do not think it is at all ridiculous on my part to show that there are methods by which this can be attained at a small risk and absolutely no loss to those giving the guarantee. If Government gave a guaranteed dividend, naturally they would want some supervision over the lines. Mr. Walker talked of the traffic increasing so much for eleven years, but he will be sorry to hear that it has fallen off very much now. There are cycles in the telegraph traffic of the world. Another of Mr. Walker's remarks was that the companies had not followed out the principles I had referred to of laying by a large reserve; but that has arisen from the fact that they are not all prosperous, and some of them, indeed, pay no dividend, and have no reserve to speak of.

A great deal has been said about the code. I beg to repeat it was the companies that introduced the code. I do not yield to any man in my enthusiasm for codification. When we were laying the first cable we talked about code language, and we have never faltered in our desire to have a good code. I have been for ten years the advocate of an authorised code, and at the last Conference the subject was passed by a large majority at two of the committees, but rejected by the full committee; and the reason why I advocated an authorised code was that we had many words that were very difficult and bewildering to our clerks, occupying four times as long to transmit as ordinary language. They were illegitimate words, which have given rise to a great deal of disagreeable correspondence and a good many meetings of the companies to try and suppress them. I have handed round the room a few prints with reference to these words which I happen to have at hand. I hope the meeting has no impression whatever that the companies desire to abolish code, or introduce anything other than what we would call a fair code. We have allowed eight languages, and we do not care whether you find 100,000 or 200,000 words in these languages, but I would like it to be established that there are certain books of reference to show that we are not being taken advantage of. I need not add anything more. I think, if my paper is carefully read, it will be seen that I have written with the view not of making any definite proposition, but of showing that there are plans for cheapening telegraphy, and it is most important for the interests of commerce and federation that this should be effected.

The CHAIRMAN then put the following resolution to the meeting, which was carried unanimously:—"That the reduction of the Anglo-Indian and Colonial postal and telegraph charges, and the neutralisation of cables, be commended to Her Majesty's Government and to the Governments of the various colonies as desirable in the interests of the Empire and of international commerce; and this Congress strongly urges Her Majesty's Government to advance such objects, when possible, by international treaty, and by inviting the joint action of the Colonial and Indian Governments thereon. In this view the Congress particularly points to the desirability of the assimilation of the Colonial and Indian postal tariffs to those of the minimum tariff of the International Postal Union."

SCIENCE AND ART.

The close relation which from the remotest antiquity has subsisted between Art and Science was agreeably brought into prominence the other evening, when one of the foremost branches of applied science assembled together in the splendid rooms of an Institute identified with the progress of that branch of pictorial art for which England is the most famous of modern nations. The conjunction was probably accidental, though the practical question relating to the preservation of water-colour drawings which the exhibition now on view is intended to solve may have had something to do with it; but one could not help being reminded of the fact that, although in the course of ages they have changed places in relative importance, Science and Art have never parted company, continuing as they ever have been, and probably ever must be, the one the helpmate of the other. The marked interest displayed by Prof. HUGHES'S friends in the rare pictorial show on the walls of the ROYAL INSTITUTE OF PAINTERS IN WATER COLOURS, marred only by the unfortunate absence of a catalogue, proved that the eye of Science is more appreciative and discriminating in matters of Art than its votaries are willing to acknowledge. It is rather the fashion for Art to depreciate Science; only the vulgarist of scientists ever run down Art.

Judged by the experience of history, these two great products of the higher human faculties always attain their supremest perfection at one and the same time, the period of greatest development in the fine arts being that of the most remarkable achievements of Science. Art only attained its modern stature with the help of Science; and Science has made most rapid growth when fostered by an age essentially artistic. The Renaissance was a scientific revival. LEONARDO and MICHAEL ANGELO were scientists by nature; the former boasted himself a master of almost all the sciences, and was certainly accomplished in some that had no apparent association with painting in oil. The greatest of living art critics prides himself on being a man of science, which if not an honour is at least a compliment to that field of intellectual labour in which he has won fewest laurels. It would be difficult to say precisely where a bias of mind in one direction or the other becomes a hindrance to the fullest development of powers; but it is certain that art has been known to degenerate into mechanism through too much science; whilst it would be hard to point to any scientific revival being degraded by over much imagination. For lack of it Science, as we may often witness, is but a lifeless machine; whereas, on the other hand, the scientists of greatest renown in ancient or modern times, have been men of vivid imagination and keenest insight, qualities which are strictly those of the poet and artist. Science is almost always a patron of the arts, and thus acknowledges the unconscious debt it owes them; and if the arts are a little shy of Science, it may in fairness be owned that their obligations are fewer and their apprehensions more just.

The occasion of the exhibition of old water colour drawings, to which members of the Society of Telegraph-Engineers were among the first visitors, seems to have been intended to demonstrate the permanency of that class of paintings, against the contrary assertion lately put about, to the alarm of everybody who possess water colour drawings of any value. The case against their permanency is fully stated by Mr. J. C. ROBINSON, in the *Nineteenth Century* for June, from which we extracted an interesting paragraph a fortnight ago. There can be no doubt that in sunlight water colours do fade; and our washerwomen would have told us the same without the help of a high-class magazine. The bleaching power of the sun over artificial colours is beyond dispute; just as is its power to give colour to the natural rose, whether on stems of summer garden or cheeks of healthy maiden. But there are evidently differences of colouring, both as regards method and medium, otherwise the majority of the pictures now exhibited on the walls of 191, Piccadilly would long ago have become mere shadows of their former glory, instead of being, as most of them really are, true and brilliant as if fresh from the painter's easel. A good many modern water colour drawings of priceless value have been ruined by exposure to daylight not directly in the sun's rays. On the other hand, a vast number of older paintings have survived exposure of all kinds, and remain to us apparently unimpaired. This is undeniable, whatever Mr. Robinson may argue to the contrary. Some of the newspapers, discussing the question, lay all the blame of fugitivity on the pigment; it would be just as safe to lay it on the paper. Pigments differ greatly in permanency; but so does the material on which they are imprinted, as every good housewife knows. The great art authority already referred to has always insisted on the importance of the drawing paper when the drawing is intended to survive; and has even recommended that the State should take upon itself the duty of manufacturing a standard paper of highest quality, duly stamped. Mr. RUSKIN knows what he is talking about, and we may conjecture that pigments wisely selected, on paper carefully manufactured, will stand any kind of light without serious detriment.

Digitized by Google

As, however, we have to deal with pictures which are not always painted under these favourable conditions, and have to preserve them as best we may, the question raised by Mr ROBINSON as to the relative effect of sun light and electric light becomes interesting, and is one which we hope the scientist will, as he suggests, take up and solve conclusively. The incandescent lamp is most likely to give favourable results; and it would be well worth while to institute with that kind of lamp a series of experiments similar to that which Mr. ROBINSON has carried out with water colours exposed to the sun. It was almost a surprise, and quite a disappointment, that the *conversazione* last Tuesday week was not illuminated by electricity. But we cannot blame the ROYAL INSTITUTE OF PAINTERS IN WATER COLOURS for not trying an experiment with so rare a collection of paintings until some trustworthy data to go upon are forthcoming. The same thought probably occurred to the eminent electricians who inspected these pictures the other evening by the light of gas jets from the ceiling. The friendly relations between Science and Art could not be better exemplified just now than by discovering a sure means of preserving such works of art as are artistically strong but scientifically weak.

CORRESPONDENCE.

NERVOUS FORCE AND ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As no opinions concerning my experiments appeared in your last issue, I now write to complete my narrative, and shall then subside. The nearest approach to my experiments that I have yet been able to find is one by Dubois Reymond, who found that a current was produced on the contraction of a muscle. I am not aware that he went beyond this. I explain how it is that the legs of a person whose spinal cord has been injured or severed are responsive to tickles and pricks in the following way:—

The grey substance of the spinal marrow being identical with that of the brain, it follows that the blood must have a similar effect upon it. But the electricity generated in the spinal cord below the injury resembles a statical charge in that there is no electromotive force to send it through the nerves. When the leg is pricked, it must be assumed that the equilibrium of the charge is disturbed, and by some means it is caused to flow along the motor nerves, making the limb contract. I think it was Descartes who said that all the lower animals were mere machines. I should be sorry to believe that; all animals which possess a "will" cannot be machines. But I can quite conceive that a decapitated cock and animals in a like unfortunate condition are reduced to the rank of machines. Dr. Stone, in his recently delivered lectures on the electrical conditions of the human body, mentioned six cases of hemiplegia which were tested for resistance, and in each case the paralysed side offered the least resistance. I am disposed to think that this was not due to the fact that degenerated tissue conducts better than sound muscle, but, that in the healthy side the current from the battery had to fight against the current already flowing in the form of nervous force, whereas in the diseased side there was no such counter-current.

Again, we hear a noise for the first time; if that noise continues regularly, we cease to notice it, but as soon as it is discontinued, we are once more sensible of its previous existence. An instance of this is to be found in church-sleepers. They hear the text given out, and then become sweetly oblivious of the rest, and wake up with a guilty start when the sermon is over. These phenomena connected with the auditory nerves closely resemble the extra currents produced on opening and closing the circuit in a coil of wire. It is the unusual rush of the current that makes us attend to a sensation. I regard the case of church-sleepers as a most noteworthy and interesting example of the hypnotic effect of the electric current; an effect which is almost inevitable when the sermon is delivered in monotone.

I should trespass too much on your space were I to dilate further on this very wide subject.—Yours, &c.,

ARTHUR WILLEY.

45, Gladstone-avenue, Noel Park, N., July 7.

IRON WATCHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the event of the above not having already been brought to the notice of your readers, will you allow me to suggest an iron case for a watch as a very ready specific against magnetism, for any who are interested in dynamo machines. I had a watch made with an iron case last year, and my experience is most satisfactory; the iron, besides being cheap and enabling one to put additional value into the works, affording also a good material for the deposition of any rare metal which may lend a charm to the idea.—Yours, &c,

Westfield, Reading, July 5th, 1886. WALTER PALMER.

THE DEAD TURNS OF DYNAMOS.

BY PROF. SILVANUS P. THOMPSON, D.SC., B.A.

Everyone who has worked with dynamo machines knows that when a self-exciting dynamo is running the electromotive force is not exactly proportional to the speed of the machine, but always somewhat less. Every dynamo acts as if a certain number of the revolutions in a second did not count—as if a certain number of the turns were "dead." The present article is devoted to a discussion of the "dead turns."

Suppose we write E for the electromotive force of a dynamo, and n for the number of actual revolutions per second. Then, *if* the field-magnets were separately excited in some way to absolute saturation we should have,

$$E = n B \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where B stands for the value in proper units of the "cutting" of the saturated magnetic field by the revolving coil in going round once. This quantity B depends both on the armature and on the field-magnets. In the notation employed in my treatise it is the same thing as $\frac{1}{\sigma}(4 A G \kappa)$; or, calling $\frac{G\kappa}{\sigma} = Y$, then $B = 4 A Y$. If we take as our unit of "cutting," the cutting of 10^8 magnetic lines of force as defined in the C.G.S. system, then E will be in volts. But when a machine excites itself it never absolutely saturates its own field-magnets, and therefore E never is as great as n times B. It may be n times something less than B, or may be B times something less than n. This latter way of expressing the matter is the convenient one for our present purpose. We will therefore write the fundamental equation of the dynamos from our new standpoint as

$$E = (n - n') B, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where n' stands for the number of "dead turns."

We have next to find out what n' the number of dead turns depends upon, for it certainly does depend on certain things inherent in the action and in the construction of the machine as well as on the resistances in circuit. And first, we must point out that, quite apart from the question of self excitation, there are two causes of "dead turns" to be found in all machines (even in separately excited and alternate current machines), viz., in the prejudicial actions of self-induction, and of the eddy-currents that arise in badly-designed machines. A very good example of this is afforded by the contrast between the Brush machine, with its old cast iron armature, and the same machine with its new laminated armature. The curves connecting speed and E.M.F., when run in a constant and separately-excited field, are given on p. 190 of my treatise (second edition). The old armature running at 430 revolutions per minute gave the same E.M.F. as the new armature running at 360. The old armature running at 800 gave the same E.M.F. as the new armature at 700. The old armature at 1,200 gave the same E.M.F. as the new armature at 760. The windings being identical, the difference is due partly to quality of iron, but chiefly to saving of eddy

Digitized by Google

currents by proper lamination. The dead turns of the old armature exceeded those of the new armature by figures which rose successively from 70 to 100 and finally to 440, increasing much more than in proportion to the speed, more nearly in proportion to its square, as, indeed, is the case with reactions producing eddy-currents. With both armatures there would also be a certain number of dead turns—probably small—due to the self-induction of the armature coils, proportional to the first power of the speed.

Such reactions are present more or less in all machines; but in most well-designed ones eddy-currents and self-induction are reduced to an insignicant minimum. The case taken above was an exaggerated one, but was chosen expressly to show that even in a separately excited dynamo dead turns may arise from these causes.

But we have rather to deal with the ordinary series-wound and shunt-wound dynamos that excite themselves, for they have dead-turns due to a wholly different cause, namely, that they have to spend part of their currents in self-excitation. In all that follows we assume the absence of self-induction and of eddy-currents.

Dead Turns of Series Dynamos.

We must examine the equations of the series dynamo to get at this matter. The equation for the current i is given on p. 279 of my treatise as:

$$i = \frac{1}{\sigma}\left\{\frac{4\,n\,A\,G\,\kappa}{R+r_a+r_m} - \frac{1}{S}\right\};$$

in which expression A is the armature coefficient, G and κ the geometrical and magnetising coefficients of the field-magnet, S the number of magnetising coils, σ the saturation coefficient, R the resistance of the external circuit, r_a that of the armature, and r_m that of the field-magnet coils. This we may re-write as

$$i = \frac{n\,B}{R+r_a+r_m} - \frac{1}{\sigma S}.$$

But, as pointed out in my treatise (p. 284) as a most important point, the quantity $\frac{1}{\sigma}$ is the same thing as that number of ampere-turns which will bring down the effective magnetic permeability of the iron of the machine to half its initial value, or will bring up its state of magnetisation to exactly half saturation. I have called the current that will half-saturate the magnets the "diacritical" current, and denote it by i'. Then, $S\,i'$ is the diacritical or half-saturating number of ampere-turns, and is equal to $\frac{1}{\sigma}$. Hence, the second term of the expression on the right-hand side of the last equation is equal to $\frac{S\,i'}{S}$ or to i'; and so we get

$$i = \frac{n\,B}{R+r_a+r_m} - i'. \quad \ldots\ldots\ldots \quad (3)$$

Now, examine the first term of the expression on the right hand side. We see that $n\,B$ is the same thing as the value of E at that speed if the field-magnets were somehow excited up to absolute saturation. Denote this "maximal" value of the E.M.F. as $\bar{E}$; then we see that this is (by Ohm's law) an expression for the "maximal" current $\bar{i}$ that would be sent through the given resistances by exciting the dynamo independently to saturation and running it at speed n. Or, in symbols,

$$\frac{n\,B}{R+r_a+r_m} = \frac{\bar{E}}{R+r_a+r_m} = \bar{i}$$

giving us for the actual current of the dynamo,

$$i = \bar{i} - i' \quad \ldots\ldots\ldots \quad (4)$$

This is a proposition of great interest, due to Dr. Frölich, and may be stated in words as follows: *The actual current of a series dynamo is always equal to the difference between the maximal current* (at the given speed and with the given resistances, as above defined) *and the diacritical current.*

Now go back to equation (3). It is clear that if i can be written in terms of a speed, a constant B and the resistances, the diacritical current i' may be similarly written, or

$$i' = \frac{n'\,B}{R+r_a+r_m}. \quad \ldots\ldots\ldots \quad (5)$$

Here, obviously, n' is that speed at which the dynamo must be driven, so that if its field-magnets were separately excited to saturation, it would send through the given resistances a current equal to the half-saturating or diacritical current. Put this expression for i' into equation (3) and we get this result:—

$$i = \frac{n\,B}{R+r_a+r_m} - \frac{n'\,B}{R+r_a+r_m}$$

or,

$$i = \frac{(n-n')\,B}{R+r_a+r_m} \quad \ldots\ldots\ldots \quad (6)$$

Comparing this result with equation (2) we see at once that we have here come back to the dead turns, and that equation (5) connects together directly the dead turns and the diacritical current. Hence we get for the dead turns

$$n' = \frac{i'\,(R+r_a+r_m)}{B}$$

or, putting in the value of B,

$$n' = \frac{\sigma\,i'\,(R+r_a+r_m)}{4\,A\,G\,\kappa}$$

But

$$\sigma = \frac{1}{S\,i'}$$

Hence

$$n' = \frac{R+r_a+r_m}{4\,A\,G\,\kappa\,S} \quad \ldots\ldots\ldots \quad (7)$$

This gives us some very definite information about the dead turns. In the first place, the dead turns are the same at all speeds of the machine (neglecting the slight effects of self-induction and eddy currents). In the next place, the dead turns increase with the resistance of the circuit. They can be diminished, however, by increasing the number of coils of wire on the armature, or by increasing the number of coils of wire on the field-magnet, provided at the same time the gauge of wire be increased so that r_a and r_m are not altered. Lastly, looking at G and κ, which depend on the quality, quantity, and form of the iron, we see that the better the magnetic circuit of the dynamo is the fewer will be the number of dead turns. Knowing, as every electrical engineer does, how disadvantageous high speeds are, both from the electrical and from the mechanical point of view, the great importance of saving dead turns is at once apparent. And it is satisfactory to observe that those very means that must be taken to diminish dead turns—namely, reducing internal resistances, and so designing the ironwork as to get the very best magnetic circuit—are already known for other reasons to be the essentials of a well-designed and efficient dynamo.

The next point to consider is the bearing of the above matters upon the least speed of excitation. It is known that for every given dynamo put in a circuit of given resistance there is a certain speed to be found such that, if run below that speed, the machine will not excite itself at all. This can be readily found by calculation from equation (3) or from equation (6). For, give to n a particular value n_1, such that $i = 0$, and we obtain an expression of the conditions for the limiting case, where the machine just does not excite itself. Equation (3) then becomes

$$0 = \frac{n_1\,B}{R+r_a+r_m} - i'$$

or,

$$n_1 = \frac{i'\,(R+r_a+r_m)}{B}$$

But, by equation (5) $i' = \frac{n'\,B}{R+r_a+r_m}$,

whence

$$n_1 = n';$$

that is to say n_1, the least speed of self-excitation, is the same thing as the dead turns. This result is obtained even more immediately from equation (6), in which, if one writes n_1, for n and equates to zero, the equality of n_1 with n' is at once evident.

Digitized by Google

It appears, then, that the least speed of self-excitation also depends upon the resistances of the circuit, and on the goodness of design and quality of iron in the magnetic circuit. It is because the least speed of excitation varies with the resistance of the circuit that I object to its being called the "critical speed" of the dynamo, a term given, wrongly, as I think, by some. I hold that this term ought to be reserved for the speed that is the proper one for self-regulation in the compound dynamo; which speed does *not* vary with the resistances of the circuit. The critical speed of self-regulation depends on the machine itself, not on anything in the circuit. The least speed of self-excitation depends on the resistances of the circuit as well as on those of the machine. Therefore, to call this the critical speed *of the machine* would be misleading. I prefer the term "dead turns."

Dead Turns of Shunt Dynamos.

It is easily shown that a similar argument is applicable to the shunt dynamo. Here, also, we may begin by writing

$$E = (n - n')B \quad . \quad . \quad . \quad . \quad . \quad , \quad (8)$$

This should be compared with the equation for the shunt-dynamo on p. 291 of my book,

$$E = \frac{1}{\sigma}\left\{4nAG\kappa - \frac{r_s r_a\left(\frac{1}{R}+\frac{1}{r_a}+\frac{1}{r_s}\right)}{Z}\right\},$$

where Z is the number of windings in the shunt-coil. The quantity $\frac{1}{R}+\frac{1}{r_a}+\frac{1}{r_s}$ is the same thing as the whole conductivity of the machine with its circuits, from terminal to terminal, and may be writen $\frac{1}{\mathfrak{R}}$, where $\mathfrak{R}$ is the resistance of the system from terminal to terminal. Remembering also that there will exist a diacritical shunt current i'_s such that Zi'_s ampere-turns will half saturate; also that $r_s i'_s$ may be written as a diacritical number of volts e', we may insert these and write

$$E = nB - \frac{r_a}{\mathfrak{R}}e'; \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

or, remembering the relation between the volts at terminals e and the whole E.M.F. to be

$$\frac{e}{\bar{E}} = \frac{\mathfrak{R}}{r_a} = \frac{e'}{E'},$$

we have $E = nB - E'$

or $E = \bar{E} - E' \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$

where $\bar{E}$ is the maximal value of the electromotive force of the armature (at that speed) and E' its diacritical value.

Comparing equation (8) with equations (9) and (10) we see that

$$E' = n'B = \frac{r_a}{\mathfrak{R}}e' = \frac{r_a r_s}{\mathfrak{R}}i'_s$$

and $$n' = \frac{r_a r_s i'_s}{B\mathfrak{R}}$$

or, putting in for B its value $\frac{4AG\kappa}{\sigma}$

$$n' = \frac{\sigma i'_s r_a r_s}{4AG\kappa\mathfrak{R}};$$

and, since $$\sigma = \frac{1}{Zi'_s}$$

$$n' = \frac{r_a r_s}{4AG\kappa Z\mathfrak{R}} = \frac{1}{4AG\kappa Z}\left\{r_s + r_a + \frac{r_s r_a}{R}\right\} \quad . \quad (11)$$

from which it appears that in the shunt dynamo the dead turns are diminished by increasing the windings on armature and field-magnets and by bettering the magnetic circuit; but that they depend on the resistances in a more complex way, the internal resistances going to increase the dead turns, the external resistance helping to diminish them as it increases, but increasing them as it diminishes; the dead turns becoming infinitely great when the machine is short-circuited.

For compound-wound machines several curious cases arise, and the calculation of the dead turns is less simple.

LITERATURE.

New Theories of Matter and of Force. By WILLIAM BARLOW. [Sampson Low, Marston, Searle, and Rivington. 1885.]

My doxy is orthodoxy, your doxy is heterodoxy is what each man practically says, although when driven into a corner he falls back upon authorities. It must of necessity be that every one who thinks for himself is more or less heterodox. If it were not so knowledge would be finite, and we should, in some branches at least, have almost reached the bounds. Many of our so-called scientific men act as if they really had explored the uttermost regions, and that no new fields were left for science to conquer. Their dicta are to be accepted without question, and woe to the poor wight who presumes to criticise. History is forgotten or ignored, as are facts; for, notwithstanding the intense conceit of modern science, which leads to hero-worship such as the world never knew before the nineteenth century, facts will prove too strong for theories. The Assyrians, Egyptians, and Greeks framed theories to suit their facts; the moderns have done nothing more. The theories differ in that the latter have to suit more facts, and a thousand years hence new theories will be in vogue to suit the extended accumulation of facts. We are not much concerned with new theories; what we really want is new facts. Given the latter, the former can take care of themselves. So far as we know—with, perhaps, a single exception—no theory ever advanced or generally accepted is entirely satisfactory. These are our views concerning theories, and we look on Mr. Barlow's as one more added to the number, one which may or may not force itself into prominence, gain adherents, be accepted for a time, to be in its turn replaced by another. It must not be thought from what we have said that we in any way despise those who put forward theories; not so, we believe the work they do is extremely valuable, but it should not be put before the obtaining of facts. The theorist inventor is the generaliser, and the man who can generalise is almost as valuable to the world as the man who can investigate.

It is almost impossible to attempt to abstract the theory of Mr. Barlow, so we shall as far as possible allow him to speak for himself. Briefly, he puts on one side the idea of sixty odd elements, and believes the matter with which we are acquainted to be derived in all its forms from two differently compressible ethers, which, at the creation of inorganic matter, had a force impressed upon them from which they have ever since been endeavouring to recover. Mr. Barlow says:—

"All matter consists of two elementary substances, which when uncombined, and not subjected to extreme pressure, resemble gases in that they are compressible and elastic, and that as they are freed from pressure their tenuity becomes practically unlimited.

"They differ from each other in that when, being under the same initial pressure, the same increment of pressure is applied to both, the one has, in all cases, a greater increment of contraction than the other, and we accordingly designate them *the more readily compressible ether* and *the less readily compressible ether*.

"At some low pressure the density of the more readily compressible ether is less than that of the less readily compressible ether, and thus a certain pressure is conceivable, subjected to which the two ethers have the same densities. and which forms, therefore, a critical point of such a nature that for equal pressures upon the two ethers below it, the less readily compressible ether has the greater density, while for equal pressures above it the more readily compressible ether has the greater density.

"These elemental ethers are distinguishable from gases by the far greater fineness of their ultimate particles, if the fact of their elasticity requires us to suppose the existence of such, so that for all practical purposes they are to be regarded as homogeneous. And they also differ from gases in requiring a far greater force of compression to cause them to approach the greatest possible condensation.

"Some cohesion or stickiness subsists among the ether particles at all densities, both between particles of the same kind and particles of divers kinds of ether; the law

Digitized by Google

which regulates the degree of this cohesion being that the total amount of cohesion in any given mass of the same kind of ether is constant whatever the density. To put this hypothetic law in algebraic form :—If a given mass of ether is in the form of a cube, the force necessary to just overcome the cohesion subsisting, say, in a plane section taken parallel to one of the faces of the cube, and *simultaneously* to break away particle from particle throughout this section, is constant whatever the magnitude of the cube, and therefore the force necessary to overcome the cohesion in a unit of such surface, and which force we may take as the unit of the force of cohesion, varies as $\frac{1}{l^2}$, if l be the length of a side of the cube.

"In the case of cohesion between two different kinds of ether it is supposed that the density of the less dense of the two regulates the law just stated.

"The cohesion, which thus increases with increase of density, modifies the expansive force of the ethers, so that as they are more and more highly condensed they manifest less and less force of elastic expansion on release from pressure, till at a sufficiently high condensation they manifest none.

"Further, in the case of extremest condensation the viscosity of the ethers, *i.e.*, the degree of resistance they oppose to the relative motion of their parts, becomes indefinitely great, so that they reach a perfectly solid state.

"Finally, the ether particles, like all matter with which we are acquainted, have the property of inertia.

"It is supposed that the origin of the two ethers just described, preceded in time the application of any external force affecting them ; and in their primary condition they may be conceived as without motion, or regularity of disposition in space, and uncompressed."

Starting with these fundamental assumptions, the author goes on very ingeniously to show how the various phenomena connected with electrical and other branches of science are explained by them. We cannot enter into any discussion of the "theory," as, so far as we can see, such a course would serve no practical purpose. Any reader interested in the subject must peruse the work itself.

OLD CABLE STORIES RETOLD.

BY F. C. WEBB.

(*Continued from page 430, Vol. XV.*)

The Persian Gulf Cable of 1863-4.

Although the cable laid from Kurrachee to Suez, for the Red Sea and India Telegraph Company, had proved a costly failure to our Government, and consequently to the country—for the four per cent. absolute guarantee for fifty years saddled the country with a considerable sum—yet so determined was Government to obtain telegraphic communication with India that steps were at once taken towards accomplishing that object by means of land lines, *vid* Constantinople and Bagdad to Bussorah and Fao, and thence by a submarine cable along the shallow waters of the Persian Gulf to Kurrachee, where the land lines of India had their western terminus.

The history of how this line was initiated does not belong to the subject of "Old Cable Stories Retold." It must, however, have been very shortly after the failure of the Kurrachee-Aden and Suez cables that Lieut.-Col. Biddulph, R.A., was engaged to erect a land line with two wires from Constantinople through Bagdad to Fao.

The late Lieut.-Col. Patrick Stewart (then Major) was intrusted by the Government of India with the superintendence of the work of establishing the cable from Fao to Kurrachee, touching at Guadar (on the Mehran coast), Mussendom (on the Arabian coast), and Bushire (the principal port of Persia).

The construction of the lines through Persia was entrusted to Lieut.-Col. Champain, R.E. (then Captain), and Sir Arnold Kemball, H.M. political agent at Bagdad.

A land line with two wires was also being constructed along the Mekran coast, between Kurrachee and Guadar, under the superintendence of the late Mr. Isaac Walton, the route having been previously surveyed by Sir Frederick Goldsmid. Lieut.-Col. Stewart's first step was to take the advice of scientific men as to the type of cable to be employed, and it was finally decided on as follows :—A copper conductor, to weigh 225lb. per nautical mile, to be formed by a process proposed by Mr. Latimer Clark, which was to have the advantages of a strand conductor, viz., immunity from breakage inside the insulating medium, combined with the advantage of the smaller surface given by a single cylindrical conductor over one composed of strands. To accomplish this the copper was to be formed by four pieces having each the section of a quadrant of a circle. Four of these, properly placed, would form a circular conductor, and were to be kept in place by a fifth piece—a tube—in which the other four pieces were placed. The mode of manufacture was to cast the five sections in stout bars, to be placed together, and then drawn down to the required size. The conductor thus formed was to be covered with three coatings of gutta percha, with Chatterton's compound between the coatings.

There was no single contract entered into for the making and laying of the cable. The gutta percha covered copper wire was bought from the Gutta Percha Company, Wharf-road. Tenders were called for the serving of wire covering and outer serving. Mr. W. T. Henley's tender was accepted, being some £13,000 below that of Messrs. Glass and Elliot.

This decision, it may here be mentioned, resulted in the amalgamation of Glass and Elliot with the Gutta Percha Company soon afterwards, forming the Telegraph Construction and Maintenance Company. Messrs. Bright and Clark were engaged not only to watch the manufacture of the cable, but also to superintend and carry out, without the intervention of any contractor, its shipment and submergence. At the Gutta Percha Works, in Wharf-road, the late Mr. J. C. Laws, assisted by Mr. F. Lambert, tested the single coils of wire, and made certain careful experiments on the effects of temperature on the resistance of gutta percha, and from this data curves were formed by means of which the observed resistance at any temperature could be reduced to that which any particular wire tested would give at the chosen standard temperature of 75° F., to which temperature all tests were reduced, and were thus directly comparable whatever the temperature might be at which the test was performed. At Mr. Henley's works I superintended the testing, assisted by Mr. Afred Brasher, Mr. J. T. Woods, the late Mr. T. Alexander, and the late Mr. E. Donovan.

There was one fault that occurred in one of the sections which is worth mentioning. It was very minute and variable ; but what puzzled us most was that with high battery power it increased its resistance, even where reversals were used. It was whipped by a clock night and day with high battery power, and we were at last able to localise it by the loop test to within a short length. This was cut up, and when reduced to within a few fathoms the core was stripped, and the fault found to be caused by a small stone pressing into the gutta percha. The theory that accounted for its increase in resistance with high battery power was that the strong currents decomposed and consequently destroyed the film of moisture that laid between the stone and its matrix in the gutta percha. It gave us a deal of trouble, but we were proud of routing him out at last.

The work of manufacture proceeded, of course, night and day, and some of our staff had to be there at night, for our tests were the only tests taken, Mr. Henley being satisfied with them. If anything had gone wrong with them between, say, 10 p.m. and midnight, I am afraid that the attractions of North Woolwich Gardens, then in full swing, would have had much to answer for.

It soon became necessary to think about ships. The cost of sending 5,000 tons of cable (exclusive of tanks, water, and machinery) round the Cape in steamers would have been very great. The question of employing sailing ships to take the cable to Bombay and there utilising the large paddle frigates of the disbanded Indian Navy was therefore carefully considered at the India Office and found to work out cheaper than steamers all the way. There was every prospect of calm

Digitized by Google

weather, and even if cutting and buoying, on account of strong head winds, should become necessary, there could be no great delay or risk, as the depth of water along the whole line did not exceed sixty fathoms. Sailing ships were consequently decided on and tenders sought. There were, of course, a number of tenders sent in, and it must have taken a considerable time to sort them down, judging from what I myself witnessed of the same process when two ships only were required for the second Persian Gulf cable in 1868; but I had nothing to do with that part of the work in 1863. At last the following sailing ships were taken up:—The "Tweed" (formerly the "Punjaub," paddle frigate of the Indian Navy), the Assaye (formerly also a paddle frigate of the Indian Navy), the "Kirkham" (an iron ship), the "Marion Moore," and the "Cospatrick," a teak ship, built at Moulmain. The ss. "Charente," re-christened the "Amberwitch," was also bought and entirely refitted with new deck houses, &c., and re-rigged, previous to her being fitted with tanks and deck machinery as a permanent repairing ship, to be stationed at Kurrachee for the maintenance of the line.

It is curious that although a repairing ship was thus thought of and provided from the first, and although a large staff, which comprised numerous experienced and highly qualified electricians, was carefully selected for the permanent service, no person was engaged who had ever even seen a telegraph cable repaired. The ship was to be commanded by Lieut. Arthur Stiff, I.N., who had for years been engaged under Captain Constable, I.N., in surveying the Persian Gulf, and on whom would have devolved the duty of repairing the cable at the very first break-down, although his great knowledge of the Gulf could scarcely have compensated for his total inexperience in submarine cable engineering.

The ships were each fitted with three cable tanks, with Newall's patented cones and rings, a royalty being paid to Mr. R. S. Newall, although by law Government need pay no royalties. The cones were built up of wood, secured by angle irons to the bottom of the tanks. The rings were of gas pipe, with radiating arms, having a short piece telescoping into their ends, with set screws to clamp them, so that when once adjusted to any particular height the ring could not move horizontally. To resist upward pressure, straight pieces of gas pipe were attached to the radiating arms, and these pieces passed through the deck, cast-iron collars being fixed to the deck, these collars having screws to clamp the uprights in. Thus the rings—when lowered by their tackle to any position—as the surface of the coils lowered, were held rigidly in position. Loops in the rings, temporarily closed at their mouths by an iron block held by two tapered pins, permitted the lower end of the coil to pass up practically inside the ring; for on knocking out the two pins the block fell to the bottom of the tank, and the part of the cable leading to the next tank was inside the ring, thus allowing the bight to pass up out of the tank without any unscrewing of bolts to open the ring. On the second Persian Gulf cable I improved this arrangement to a self-acting opening piece since adopted by the India Rubber Company and the French Government. Each sailing ship, except the "Cospatrick," was fitted with a paying-out machine, so that there was no occasion to shift machinery from one ship to the other. The frames were of wood, the drum overhanging, with a break for contingencies on the drum itself. The working break pulley, for ordinary strains, was within the frame. Stern sheaves were also fitted to each ship, but no bow sheaves.

The "Amberwitch" had bow and stern sheaves, a paying-out gear, and picking-up machine. The latter had overhanging drum with internal spur gear into which the pinion worked, thus preventing any strain coming on the spokes of the drum. I believe this was the first instance of internal spur gear being adopted, or, indeed, of a picking-up machine with overhanging drum. The after knife of the machine could be made to fall away from the drum by merely pulling out a large cutter having a loop handle to it, so as to allow of the turns being taken off the drum. The bow sheave was countersunk into the side cheeks, so that by no possibility could the cable or rope get between the flange and casting.

A Gwynn centrifugal pump and engine were fitted to each ship for pumping up the tanks. Thus equipped, the ships took in their cable, in some cases two at a time, and then were taken to the Victoria Docks, where the cable was decked over in each tank. The ships left the works or Victoria Docks in the following order:—"The Marion Moore," Aug. 15th, 1863, Mr. E. Donovan in charge, with 174·92 N.M. of deep sea; "The Kirkham," Sept. 12 or 13, 1863, Mr. Walker in charge, with 181·25 N.M. of deep sea, and 6·36 L.M. of shore end; "The Assaye," Oct. 2nd, 1863, Mr. J. T. Woods in charge, with 367·98 N.M. of deep sea; The ss. "Amberwitch," Oct. 21st, 1863, with 12·5 N.M. of shore ends and tapers; "The Tweed," Oct. 24th, 1863, Mr. Moseley, with 347·53 N.M. of deep sea; "The Cospatrick," with 103·15 N.M. of deep sea, 23 N.M. of shore end, and 12 N.M. of double shore end. This ship had also five lengths of experimental cable of different types by different manufacturers. The total of cable was therefore 1,228·27 N.M., excluding the lengths of experimental cables.

ON THE SEAT OF THE ELECTROMOTIVE FORCES IN THE VOLTAIC CELL.

Prof. O. J. Lodge communicates the following, from Dr. W. Ostwald, to the *Phil. Mag.* for July:—

Riga, June 2, 1886.

After reading your memoir on the seat of E.M.F. in the pile, published in last year's *Philosophical Magazine*, allow me to express my full agreement with your views. But I further believe that it will interest you to know that there is a method of directly measuring differences of potential, whether between two liquids or between a liquid and a metal.

The method rests upon a remark of Helmholtz, that a quantity of mercury, if insulated, and arranged to form drops quickly beneath the surface of a liquid, rapidly acquires the potential of the liquid. Let T (Fig. 1) be an insulated drop-

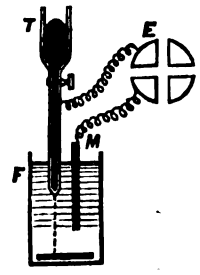

Fig. 1.

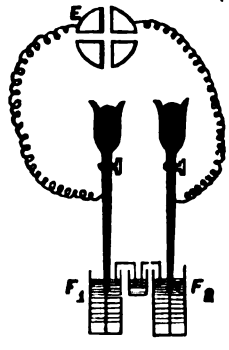

Fig. 2.

ping funnel full of mercury, which drops inside the liquid F through a fine point, and let M be a metal plunged into the same liquid; the electrometer E will indicate the true difference of potential between M and F. I have experimentally convinced myself that by careful regulation of the flow one can get the potential of the mercury to correspond with that of the liquid within about ·01 volt.

In order to measure the potential difference of two liquids, one uses two funnels (Fig. 2), and connects each of the two liquids F_1 and F_2 with a third vessel containing one of them by means of a capillary siphon, so as to prevent any mixture.

I have to thank my friend Dr. Arrhenius for the suggestion of the two funnels. I have found by this method that pretty big potential differences frequently occur between liquids, going up to ·8 or ·9 volt with dilute solutions. The E.M.F. of a Daniell cell appears to be about ·8 volt between zinc and zinc-sulphate, ·3 volt between copper and copper-sulphate; while between zinc-sulphate and copper-sulphate the difference seems practically zero. Nevertheless, since copper salts have shown some hitherto unexplained phenomena, I do not yet quite regard this result as indubitable.

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(*Continued from page 155.*)

The particular solution is propagated at the same rate as ϕ, while the other part of the solution represents a wave travelling with the velocity $1/\sqrt{\mu K}$. Since the part of the solution which travels at an infinite rate satisfies the equation

$$\frac{dF}{dt}+\frac{d\phi}{dx}=0$$

or

$$f=0,$$

we see that the electromotive force due to the change in the vector potential just balances the electrostatic electromotive force, so that until the part of the vector potential which travels at the rate $1/\sqrt{\mu K}$ comes up the resultant electromotive force vanishes. This explains how the electromotive force on Maxwell's theory travels at a different rate from the potential, and a similar explanation will apply to Helmholtz's theory. Helmholtz's equations for a conductor are

$$\sigma\nabla^2 u=(1+4\pi\theta)4\pi A^2\frac{du}{dt}-\frac{d}{dx}\left\{\nabla^2\phi+(1+4\pi\theta-k)A^2\frac{d^2\phi}{dt^2}\right\}$$

where σ is the specific resistance of the conductor; on Maxwell's theory the equations are

$$\sigma\nabla^2 u=4\pi\mu\frac{du}{dt}.$$

These equations differ by terms involving the unknown constant k; but V. Helmholtz's* investigations on the motion of electricity along thin conducting wires show that there is not much hope of distinguishing between the theories by experiments on conductors. We have seen that we can make certain equations which occur in Helmholtz's theory coincide with the corresponding ones in Maxwell's by giving particular values to certain constants. The difference in Helmholtz's and Maxwell's views as to the continuity of the currents is too serious to let us expect that we should ever get a complete agreement between the theories; and, in fact, make as many assumptions about the constants as we may, there are still differences between the theories.

In order to get as general a theory of these dielectric currents as possible, we shall investigate the consequences of assuming merely that these currents are proportional to the rate of change of the electromotive force, and write dielectric current $=\eta$ (rate of change of the electromotive force), where η is a constant which for the present is left indeterminate. In Maxwell's theory $\eta=K/4\pi$, where K is the specific inductive capacity of the dielectric; in Helmholtz's theory, η is also proportional to the specific inductive capacity. We shall denote the components of the dielectric currents by the symbols f, g, h; the components of the conduction current by p, q, r, and the components of the total current by u, v, w, so that

$$u=p+\dot{f}.$$

Let us put

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=P,$$

$$l(u_1-u_2)+m(v_1-v_2)+n(w_1-w_2)=\Sigma;$$

on Maxwell's theory P and Σ are zero.

If F, G, H are the components of the vector potential, then by V. Helmholtz's investigation of the most general expression possible for these quantities consistent with the condition that the forces between closed circuits should agree with those given by Ampère's laws,

$$F=\tfrac{1}{2}(1-k)\frac{d\psi}{dx}+\mu\iiint\frac{u}{r}\,d\xi\,d\eta\,d\zeta,$$

with similar expressions for G and H, where k is a constant, and

$$\psi=\iiint\mu\left(u\frac{dr}{d\xi}+v\frac{dr}{d\eta}+w\frac{dr}{d\zeta}\right)d\xi\,d\eta\,d\zeta.$$

Transforming this expression we see, using the same notation as before, that

$$\psi=\iint r\mu\{l(u_1-u_2)+m(v_1-v_2)+n(w_1-w_2)\}dS-\iiint r\mu\left(\frac{du}{d\xi}+\frac{dv}{d\eta}+\frac{dw}{d\zeta}\right)d\xi\,d\eta\,d\zeta$$

$$=\iint\mu r\,\Sigma\,dS-\iiint\mu r\,P\,d\xi\,d\eta\,d\zeta,$$

where dS is an element of a surface at which there is discontinuity in u, v, w.

Let us now consider the equations which hold in a perfectly insulating dielectric.

The rate of change of the x component of the electromotive force in a medium at rest

$$=-\frac{d^2F}{dt^2}-\frac{d^2\phi}{dt\,dx},$$

where ϕ is the electrostatic potential; it also equals $\dot{f}/\eta$, so that

$$\frac{\dot{f}}{\eta}=-\frac{d^2F}{dt^2}-\frac{d^2\phi}{dt\,dx}.$$

Since in this case there is no conduction current $u=\dot{f}$, and the preceding equation for F shows that

$$\nabla^2F=\tfrac{1}{2}(1-k)\frac{d}{dx}\nabla^2\psi-4\pi\mu\dot{f}.$$

substituting for $\dot{f}$

$$\nabla^2F-\tfrac{1}{2}(1-k)\frac{d}{dx}\nabla^2\psi=4\pi\eta\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\}$$

if $\dfrac{dF}{dx}+\dfrac{dG}{dy}+\dfrac{dH}{dz}=\chi$, we get, by differentiating this expression, with regard to x and the corresponding equations for G and H with regard to y and z respectively, and adding

$$\nabla^2\chi-\tfrac{1}{2}(1-k)\nabla^4\psi=4\pi\eta\mu\left\{\frac{d^2}{dt^2}\chi+\frac{d}{dt}\nabla^2\phi\right\}$$

Now, as the dielectric is a perfect insulator, there are no conduction currents, so that the density of the free electricity remains constant, and therefore

$$\frac{d}{dt}\nabla^2\phi=0.$$

From the expression for ψ we see that

$$\nabla^4\psi=+8\pi P=-8\pi\eta\mu\left(\frac{d^2\chi}{dt^2}+\frac{d}{dt}\nabla^2\phi\right)=-8\pi\eta\mu\frac{d^2\chi}{dt^2}.$$

Substituting this value of $\nabla^4\psi$ in the equation for χ, we get

$$\nabla^2\chi=4\pi\eta\mu k\frac{d^2\chi}{dt^2},$$

which represents the propagation of a normal wave with the velocity $1/\sqrt{4\pi\eta k}$.

The transverse wave is propagated with the velocity $1/\sqrt{4\pi\eta\mu}$, so that if the view that light consists of electric or magnetic disturbances be correct, since experiment shows that this velocity is very nearly equal to $1/\sqrt{K\mu}$, we must have $4\pi\eta=K$ or $\eta=K/4\pi$, which is Maxwell's theory. So that if we assume that light is an electric phenomenon, then in those media in which its velocity $=1/\sqrt{\mu K}$ Maxwell's theory that the electric currents flow like an incompressible fluid must be true.

If α, β, γ are the components of the magnetic force, then, since

$$F=\tfrac{1}{2}(1-k)\frac{d\psi}{dx}+\mu\iiint\frac{u}{r}\,d\xi\,d\eta\,d\zeta,$$

we see from Ampère's formula for the magnetic force due to a circuit that

$$\mu\alpha=\frac{dH}{dy}-\frac{dG}{dz}-\mu\frac{dV}{dx},$$

where V is the magnetic potential due to the magnetism in the field both permanent and induced. From these equations we get

$$\mu\left\{\frac{d\alpha}{dy}-\frac{d\beta}{dx}\right\}=\nabla^2H-\frac{d}{dz}\left(\frac{dF}{dx}+\frac{dG}{dy}+\frac{dH}{dz}\right)=-4\pi\mu w+\frac{d}{dz}\left\{\tfrac{1}{2}(1-k)\nabla^2\psi-\chi\right\}$$

* *Ueber die Bewegungsgleichungen der Elektricität für ruhende leitende Körper.* "Gessammelte Werke," Vol. I. p. 603.

Digitized by Google

instead of the equation

$$\frac{d\alpha}{dy} - \frac{d\beta}{dx} = -4\pi w.$$

We have been obliged to introduce another assumption here, viz., that the magnetic force due to an element of current is given by Ampère's expression.

We could not assume Maxwell's way of connecting currents with magnetic force, viz., that the total current flowing through any closed curve is equal to the line integral of the magnetic force round the curve, for the result can only be true when the currents flow like an incompressible fluid.

(To be continued.)

MAGNETIC RESEARCHES.*

BY PROF. G. WIEDEMANN.

Since the year 1857 I have published a series of investigations on the relationship between the mechanical and magnetic properties of bodies, and in 1877 a closely related paper on Torsion, in which I proposed to make, in continuation, observations on magnetism. In the meantime other investigators have made researches upon the same subject, which indeed are partly only repetitions and extensions of previous work in slightly different form; but partly also have constituted an actual advance, and in particular points have been supposed to be in opposition to the theory I have proposed. I may therefore be permitted briefly to mention these researches here, and to describe certain new experiments connected with them.

I. Mr. Hughes has investigated the change in magnetic moment of iron and steel, upon torsion, &c., under various conditions, as Wertheim and Matteuci had already done by means of the currents induced in a spiral surrounding a magnetic body.

He has given a series of experiments on the behaviour, during torsion, of iron wires through or round which a current is passed. I have already, in a short note published in English, called attention to the fact that the essential portion of these results had been already observed by myself in the years 1858-60. Nevertheless, Mr. Hughes in further communications after a not altogether correct or quite complete citation of earlier work, has (together with certain experiments following at once from my views) reproduced my theory as new. This theory has thus, in various quarters, been supposed to have originated with him.

Mr. Hughes passes, for instance, alternating currents through a flat iron band, surrounds the middle of this with an induction-spiral, and, in a telephone connected with the latter, hears no sounds; as was to be expected, since, with both directions of the current, the potential of the transverse and circularly-directed molecular magnets upon the spiral is zero. But if the iron band be twisted meanwhile, then, as I have expressly explained, the transversal molecular magnets take up a position inclined to the axis of the band, and partially maintain this position during the detorsion. Hence, under the influence of the alternating currents, they assume positions variouly inclined to the axis, so that the potentials can no longer be zero, or equal to each other; hence the telephone sounds. That upon the sudden springing back of the twisted band the molecular magnets may spring over to the other side, and that then the induced currents run in the opposite direction, is clear. It is equally obvious that the molecules of the iron tape may take up an inclined position upon the lateral approach of a magnet, though not spirally arranged round the axis, and that similar phenomena must result. These conclusions follow at once from my earlier results.

In connection with these and similar experiments, Mr. Hughes proposes the theory (*a*) that each molecule of a magnetic metal is an unalterable molecular magnet; (*b*) that it can be caused to revolve on its axis by means of mechanical and electro-mechanical forces; (*c*) that when there is external magnetic neutrality, the molecules and their polarities are so arranged that they satisfy their mutual attractions in the shortest possible way; and, lastly, (*d*) that if magnetism is produced, the molecules and their polarities become rotated into a given direction in a symmetrical manner, so that a north pole is produced in the one direction and a south pole in the opposite direction. Moreover, also, a symmetrical arrangement is assumed when magnetism is produced, but the circuits of attraction are not complete unless there is a keeper connecting the two poles. Hence Mr. Hughes assumes still further (*e*) a rigidity, which retains the molecules in their positions after the cessation of the active forces.

We have long been acquainted with all these propositions. They agree perfectly, so far as they are correct, with those which I have published after the earlier calculations of Weber; as, moreover, is recognised by Prof. G. Hoffmann, the reporter upon Mr. Hughes's experiments in the *Electrotechnical Journal*. It is only in regard to proposition (*c*) that he thinks Mr. Hughes has the priority. This is, however, not correct. In the second edition of my *Galvanismus*, II. (1) p. 373, § 327 (1871) I say distinctly:—"It is obvious that we may imagine an infinite number of arrangements of the molecular magnets in bodies, with each of which no external action would result. If, for example, they are arranged in circles with their unlike poles in contact, or if their poles have in each space-element all possible directions, this result will follow. The assumption of Mr. Hughes, that I have referred the neutrality of a bar to a "heterogeneous" arrangement of molecules, which is completely different from his theory of neutrality, is thus opposed to facts.

Moreover, it is incorrect that the external magnetic neutrality, whether of a new bar or in one subject to magnetising influences, is conditioned solely by the formation of closed molecular rings, such as Mr. Hughes imagines. This would be possible only with a power of perfectly free rotation of the molecules round their centres of gravity. But since experience shows that they suffer a resistance to this rotation, this arrangement can only be approximately attained; the axes of the molecular magnets must in like manner deviate from the axis of such a ring on all sides. Moreover, there is, *à priori*, no ground why any one direction should have the preference in an absolutely neutral magnet, either for the position of the separate molecular magnets, or for the rings approximately formed by their opposite attractions. The second statement of my proposition quoted above is therefore entirely justified.

Lastly, Mr. Hughes's proposition (*d*), that in visible magnetisation a "symmetrical" rotation and arrangement of the molecular magnets takes place, is only correct in the case of a symmetrical form of the body magnetised and a symmetrical distribution of the magnetising forces.

II. Sir William Thomson has endeavoured to explain the experiments which I made in the year 1858—showing that an iron or steel bar, subjected to torsion during or after passing a galvanic current through it, becomes magnetic—by assuming that the fibres of the bar assume a spiral arrangement upon torsion, and that so that the current also circulates spirally through it. At the same time he himself mentions the difficulty that the effect of torsion is constant in direction up to the strongest current which can be passed through the wire, whilst aelotropy would result only with feeble magnetisation, and moreover is opposed to the action of aelotropy upon the electric conductivity.

The above view is also opposed by the fact that, upon stopping the current through the wire, wires which have thus acquired permanent transversal-circular magnetism have produced in them by torsion a permanent axial magnetism. Moreover, the opposite behaviour of nickel and iron (see below) contradicts this assumption*. But that this cause may have some secondary action at the same time as the rotation of the molecular magnets is hardly to be doubted.

III. According to the experiments of Sir W. Thomson, the behaviour of magnetic bars of iron, on the one hand, is opposed to that of magnetic bars of nickel and cobalt, on the other hand, when subjected to longitudinal tension. Whilst the temporary magnetism of the first increases with the load under

* From the *Phil. Mag.* for July.

* Compare also Ewing's proposal of an experiment on this point, *Phil. Mag.* (5) xiii. p. 423 (1882); *Beibl.* vi. p. 809 (1882.)

Digitized by Google

a certain critical value of the magnetic force, above which it decreases, the temporary magnetism of nickel and cobalt decreases below a certain other (much larger) critical value of the magnetising force.

Reciprocally, it follows from the experiments of Barrett, that whilst (as Joule has shown) iron bars lengthen upon being magnetised, bars of nickel, on the contrary, shorten. Cobalt is reported to form an exception and to behave like iron. In these latter experiments, it is true, the purely mechanico-electro-magnetic action of the magnetising coil upon the bar was not excluded.

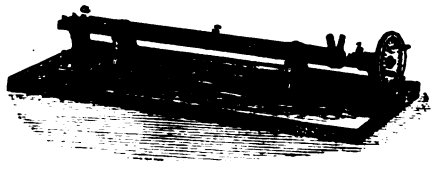
Quite in agreement with this, Mr. Knott has found that when a current has passed through a bar of nickel magnetised longitudinally, it suffers torsion in a direction opposite to that which I found for an iron bar treated in the same way.

Maxwell and Chrystal have formerly endeavoured to refer this torsion, in the case of iron, to the above-mentioned expansion which it suffers upon being magnetised. Wires magnetised at the same time longitudinally and transversely, and therefore in an obliquely spiral direction, ought to expand in this latter direction, and thus to suffer torsion in the direction determined. But with nickel, since, upon being magnetised, contraction instead of expansion takes place, the torsion ought to take place in the opposite direction, as is shown by experiment to be the case.

I have myself endeavoured to refer this phenomenon, observed in my first experiments in 1858, at least in the case of iron wires, to the obliquely spiral direction which the molecules take up in consequence of the two magnetisations at right angles to each other, and which is accompanied secondarily by a displacement of the longitudinal fibres and sections of the wires, of which, in the case of iron, the first is the most important.

The chief proof of my assumption which I had given was the phenomenon, completely co-ordinate with the above results, that a wire equatorially magnetised, whether temporarily or permanently, by a current passed through it, becomes longitudinally magnetised upon torsion.

I have now extended these experiments to the case of nickel wires. They were made essentially in the same way as the former ones. The wire, 52 centim. long and 2 millim. thick,



was stretched east and west between a clamp, *a*, screwed tight, and a clamp, *b*, coaxial with *a*, capable of rotation in an upright, and provided with a divided circle. The wire was placed end on in front of a magnetic steel mirror swinging in a thick copper box, with a fixed clamp at a distance of about 20 centim. from it. The current of a Bunsen battery was led to this clamp by long wires, placed as axially as possible, which ran at first in the direction of the axis of the wire, then coming together in a wide arc, were wound round each other and carried to the poles of the battery. The deviations of the magnetic mirror were read off upon a scale at a distance of 1 metre. In order to determine the intensity of the current as well as the temporary moments of the wires, a wire ring (Fig. 1) of 7 centim. diameter was placed in front of the mirror and coaxial with it, cut through at the bottom, and capable of vertical rotation about a horizontal axle of brass attached to it at its lowest point. The two halves of the axle were provided with copper discs dipping into mercury-troughs. A brass wire was first of all stretched in the torsion-apparatus, the current passed through it and in the proper direction through the wire ring, and this moved axically in front of the steel mirror until the latter showed no deviation, and remained without deviation when the wire was twisted. If, then, the wire ring was turned about its axis into a horizontal position, the deviation of the deflection of the mirror corresponded to the intensity of the current. Employing wires of iron or of nickel the deflection in the vertical position of the wire ring gave the temporary moment, and in the horizontal position the same increased by a quantity proportional to the intensity of the current.

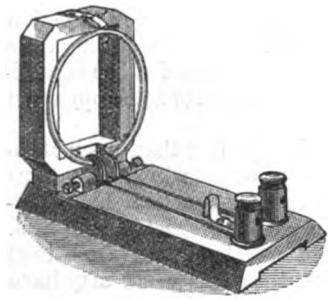


Fig. 1.

Frequently repeated experiments gave decisively the following results:—

If the current passes through an iron wire from the movable clamp to the fixed one, and if the former, as seen in the direction from the movable to the fixed clamp, is rotated in a direction opposite to the hands of a watch, the iron wire acquires a north pole at the fixed clamp, and a south pole with opposite rotation of the clamp. With reversed directions of the current opposite polarities are produced, thus confirming former results. The same takes place after stopping the current.

But if a nickel wire be employed instead of an iron wire, the results are reversed. If the current passes from the movable to the fixed clamp, and if the former be rotated in a direction opposite to that of the hands of a watch, the wire at the fixed clamp becomes a south pole, and with reversed rotation a north pole. Here also the same result is obtained after stopping the current.

Similar results were obtained also, within certain limits, upon repeated torsion in opposite directions. The deviations of the magnetic mirror far exceeded 50 or 100 scale-divisions, with torsions of $\pm 60°$ in the case of wires 2 millim. thick, so that there could be no possible doubt of the facts. The experiments may even be made with an ordinary magnetic needle in place of the reflecting magnet. The effect is less marked with thinner wires.

If the torsion acted only like an extension of the wires, it would not be easy to understand why an equatorially magnetised wire should become longitudinally magnetised by it. If we further assume that the fibres of the wires take up an inclined position, but that the molecules composing them retain their position relative to the axes of the fibres, then in all cases, if the current flows from the movable to the fixed clamp, and the clamp is rotated opposite to the direction of the hands of a watch, the wire would acquire a south pole at the fixed clamp, equally whether it consisted of iron or nickel. The expansion of the fibres might produce under the critical magnetisation an increase of polarisation in the case of iron and a decrease with nickel, but not a reversal of the polarisation.

A simple displacement of the sections, without a consequent rotation of the molecules, would communicate no longitudinal magnetism to the wire at all, and the expansion in length could produce no change.

Hence under all conditions torsion must produce a rotation of the molecules of iron opposite to that which takes place in nickel. I have already referred these rotations to the two simultaneous phenomena just mentioned, namely, to the relative displacement of the longitudinal fibres, and that of the sections of the twisted wires, whereby contiguous molecules suffer rotation in consequence of mutual friction, and in opposite directions in consequence of the two displacements. In iron the friction of the longitudinal fibres is the greatest; in nickel that of the sections predominates.

We must evidently employ these various rotations of the molecules, as I have endeavoured to do, to explain reciprocal phenomena. If the molecules of a wire are placed with their axes oblique by means of two currents passing through and round the wire, its fibres and sections must follow their rotations, as the molecules follow the displacements of the fibres and sections when torsion takes place, and consequently here also nickel must behave oppositely to iron. The change in the length of the fibres can only exert a secondary quantitative change upon the phenomenon.

Hence I believe that the phenomena I have observed cannot be taken simply as secondary phenomena to those observed by Mr. Joule and Sir W. Thomson.

SOME ADDITIONAL FACTS CONCERNING THE REIS ARTICULATING TELEPHONE.*

BY PROF. EDWIN J. HOUSTON.

Whatever the decisions of the United States Circuit Courts have been in the past, or whatever they may be in the future, there can be no reasonable doubt that, in the opinion of the general scientific world, to Reis, and not Bell, will be accorded the credit of having made the great discovery of the methods and apparatus for the electrical transmission of articulate speech. We have elsewhere maintained the following propositions, viz.:—

1st. Reis invented an instrument which he called a telephone, and which he said would transmit speech.

2nd. That this telephone operated by means of electricity, and consisted of transmitting and receiving apparatus.

3rd. That in the hands of Reis it did transmit intelligible, articulate speech; and that credible witnesses are still alive who heard it so transmit speech.

4th. That exact reproductions of the Reis apparatus, operated in accordance with his directions, will transmit speech now.

To the above it is answered, despite the published statements of Reis to the contrary:—

1st. That Reis devised his apparatus to transmit musical tones, and not to transmit articulate speech.

2nd. That there is but one method by which articulate speech can be transmitted electrically, viz., by an undulatory current, and therefore Reis never could have transmitted articulate speech telephonically, since, it is alleged, he did not use the undulatory current. Any, consequently, who imagined that they heard articulate speech through the Reis apparatus must have been deceived.

3rd. That if reproductions of the original Reis apparatus have been made to transmit articulate speech, however exact they may appear, they must have been varied in some important (although inappreciable) respect.

The transparent sophistries of the above answers are, in our judgment, completely swept away by the experiments of Mr. John R. Paddock, of the Stevens Institute of Technology, which although of an early date we have but recently received and had permission to publish. These instruments have been introduced into the overland telephone cases, on appeal to the Supreme Court. Mr. Paddock's experiments appear to clearly establish, what at the outset should have been apparent to any fair inquirer, viz., that the original Reis apparatus, without any change whatever, will transmit intelligible, articulate speech. The apparatus used by Mr. Paddock were the identical apparatus employed by Reis in his lecture before the Physical Society at Frankfort-a-M., in 1861-2. They were obtained by Hon. A. J. Keasbey, from Prof. S. P. Thompson of Bristol, England, who got them from Dr. Theodore Stein, of Franfort, Germany. Dr. Stein got them from Prof. Dr. Böttger, President of the Physical Society of Frankfort, who received them direct from Reis, after the above-mentioned lecture. The story as above told is fully substantiated by testimony taken at Frankfort-a-M.

The following letter from Mr. Paddock will, however, give the particulars at length:—

"Stevens Institute of Technology,
"Hoboken, N.J., Feb. 12, 1886.

"Prof. E. J. Houston, Franklin Institute, Phila.

"I have read with much interest your articles in the London *Electrical Review* relating to the telephone and invention of Philip Reis.

"Having facts concerning the same which have not yet been made public and which are of especial interest at this time I take the liberty of placing them at your disposal. In the summer of 1858 I came into the possession of the Original Bored Block Transmitter and Knitting Needle Receiver, exhibited by Philip Reis before the Physical Society, at Frankfort-a-M., in 1861-2. These instruments were obtained by Hon. A. Q. Keasbey, Counsel for the Overland Telephone Companies, from Prof. Thompson, of Bristol, England, who received them from Dr. Theodore Stein, of Frankfort, Germany, and he in turn from Prof. Dr. Böttger, President of the Physical Society at Frankfort, to whom *Reis himself* gave these instruments after the lecture above referred to. Their history is thus fully proved and their identity has been further established by testimony taken at Frankfort-a-M.

"The instruments were in a good state of preservation when received by me, and required no alterations or additions whatever, with the exception of a wooden support for the needle of the receiver, which was wanting, and a slight mending of the wooden case, which had become broken, evidently during transportation.

"With these instruments I soon succeeded in transmitting and receiving good articulate speech. Musical sounds and songs were easily reproduced, and it is important to remark that when the transmitter was so operating as to transmit musical sounds *best* it was also so operating as to transmit articulate speech *best*, which in view of the oft-repeated statement that the Reis instruments are capable of transmitting the one, but incapable of transmitting the other, is of especial value as showing that the same condition of the transmitter is required for both. The pitch of a musical sound was not the only results achieved by Philip Reis with his instruments, but also amplitude, and, to a good degree, quality also, as is proved by the publications of his day (see *Annual Report* of the Physical Society of Frankfort-a-M., 1861-2. Also, the *Deutsche Industrie Zeitung* for 1863).

"Mr. E. W. Smith, a practical telephone operator, assisted me in this work, and together we were able to transmit and receive many words and sentences in as clear and distinct a manner as in any modern telephone, and this notwithstanding that the instruments we were using were now nearly 24 years old, and that the diaphragm of the transmitter was made of a thin animal membrane, which soon absorbs the moisture of the breath, and then, of course, loses its tension, and fails to respond to the vibrations of the voice.

"In describing the operation of this very instrument, Philip Reis, in his lecture before the Physical Society, at Frankfort, makes the following statement:—

"'If, now, sounds or sound combinations are produced in the neighbourhood of the block, so that sufficiently powerful waves reach the opening *a*, then these sounds cause the membrane *b* to vibrate. At the *first condensation* the *hammer-like wire d is pushed back*, at the *rarefaction* it *cannot follow the retreating membrane, and the current* traversing the strip *is broken*, until the membrane forced by a new condensation again presses the strip (proceeding from *p*) against *d*. In this way *each sound wave causes a breaking and closing of the circuit.*'" (The italics are Mr. Paddock's.)

This is the description chiefly relied upon to prove that the Reis instrument operates by means of a broken current, and hence is incapable of transmitting speech, for it is maintained a current broken at each vibration cannot transmit speech, and Reis distinctly says himself that the current is thus broken, therefore, &c.

"We have endeavoured experimentally to test this most vital point so far as regards Reis and his instrument. Whether there are minute breaks in the current during the ordinary use of a microphone transmitter is a matter still in doubt and one which only indirectly bears upon this question.

"The real question is, Did Philip Reis so operate his telephone as to break the current (as he supposed he did), and if so did he obtain speech in that way (as he says he did)?

"We have operated the Reis instruments in exact conformity to his description and to this very paragrrph of that description. When thus operated 'The hammer-like wire is pushed back, but cannot follow the retreating membrane and parts from it." A continual humming is kept up as the two platinum contacts strike one another, and a succession of sparks indicate the parting of the electric current at each vibration.

"While so operating in exact accordance with the description of Reis himself the following sentence has been distinctly transmitted and received:—

"'William H. Vanderbilt died suddenly at his house on Fifth-avenue yesterday. He is said to have been worth two hundred million of dollars,' a sentence of twenty-three words, which of itself is clear proof that articulate speech can be transmitted in the Reis instrument when used with the so-called broken current. We are at present engaged in ascertaining the extent to which this old instrument will transmit speech under these conditions, and the work thus far done points to the conclusion that it is far greater than has hitherto been supposed. Photographic records will also be obtained of the vibrations produced under these circumstances, which will form an interesting subject for study, and lead to more positive conclusions.

"With reproduced forms of a later Reis instrument, viz., the cubical box form, we have transmitted speech at greater length—one sentence consisting of fifty-six consecutive words. A full statement of these experiments appears in the record of the Overland Telephone Cases, now on appeal to the Supreme Court.—With esteem and regards, very truly yours, JOHN R. PADDOCK,
"Instructor in Physics and Chemistry."

The importance of the above statements, substantiated as we do not doubt they will be, can hardly be over-estimated. If established, they sweep away completely the broad claims that the Bell Telephone Company have been so pertinaciously endeavouring to establish for Bell. They completely dispel the legal mists, that have so skilfully been maintained around the early labours of Philip Reis, and hasten the time when the general public will be ready to do what the general scientific public, the world over, has already done, viz., accord to Philip Reis the credit due to his wonderful discovery. The importance of Mr. Paddock's experiments will, perhaps, be the better understood by examining some of the recent decisions in the Circuit Courts on the legal value of the Reis apparatus as anticipations of the articulating telephone of Bell. In the recent New Orleans Telephone decision, in the case of the American Bell Telephone Company, *et al*, *v.* the National Improved Telephone Company, *et al*, Judges Pardee and Billings in their decision, spoke as follows:—"From the evidence submitted in the case it seems clear that now, in the present state of the art, neither that Reis' instruments nor any reproduction of them can be made

* From an advance proof of paper read before the Franklin Institute.

Digitized by Google

to transmit articulate speech except by changes of some form in the instruments or by the employment of Bell's method.

"We, therefore, conclude that neither Reis nor his successors anticipated the invention of Bell as set forth in the fifth claim of his application and patent, and as illustrated by Fig. 7, described in his accompanying specification."

But if the original apparatus, without any change will speak, what then?

In the American Bell Telephone Company *v.* Amos E. Dolbear, *et al*, Judge Lowell, on August 25th, 1883, in giving the opinion of the Court in this case said, "The defendant now testifies that the Reis instrument can be made to transmit speech, under some circumstances, if operated in the way which Bell has shown to be necessary. . . . . The experiment made in the presence of counsel, which was intended to prove the correctness of the defendant's present opinion, was an utter failure. But if it be admitted that the Reis instrument is capable of such use, to a very limited extent, and after a change in its proportions, and when used in a way which the inventor did not intend, still I am of opinion that it was not an anticipation of Bell."

But if the original apparatus without a change in its proportions, and when used in a way which the inventor intended, will transmit speech, what then?

Alluding to the success in making the apparatus described in Fig. 7 of Bell's original specification talk, Judge Lowell says :—"This great result has been reached by Mr. Bell entirely through the improvements described in his second patent (1877 patent), such as the substitution of a metal plate for a stretched membrane, and some others," and these early unsuccessful efforts he says are "now immaterial, for it is proved that the instrument will do the work, whether the inventor knew it or not, and in the mode pointed out."

But if it be now proved that the original apparatus will do the work, which its inventor claimed it would do (not which he hoped it would do, or was ignorant it would do), what then?

In a case that has been so full of surprises, as the telephone litigations, we must confess to considerable curiosity as to what the Courts and the legal advocates of Bell will do with the above evidence.

The author has not personally tried the experiments referred to, but hopes to do so on the first opportunity. Mr. Paddock promises to give him additional information at an early day.

Central High School, Philadelphia, June 16, 1886.

PHYSICAL SOCIETY.—June 26th.

Prof. W. E. AYRTON, F.R.S., Vice-President, in the chair.

Mr. E. M. Langley was elected a member of the Society. The following communications were read :—"On certain Sources of Error in connection with experiments on Torsional Vibrations," by Mr. HERBERT TOMLINSON. During a long series of researches on the torsional elasticity and internal friction of metals, the author has come across the following sources of error in connection with torsional vibrations. In some of the earlier experiments a horizontal brass bar was suspended by a wire and oscillated, the times of oscillation being observed by the ordinary lamp, mirror, and scale. The moment of inertia was varied by sliding two brass cylinders, suspended from the bar by fine wires, backwards and forwards along it. It was then found that under certain conditions the bar executed a few vibrations of rapidly decreasing amplitude, came to rest, and then commenced to swing again, the amplitude increasing to a maximum, again decreasing, and so on. This effect was finally traced to an approach to synchronism between the time of oscillation of the bar and that of the small cylinders about their axis of suspension, the absorption of energy being due to these being set in vibration. The effect entirely disappeared upon clamping the cylinders rigidly to the bar. On another occasion, however, the old phenomenon reappeared, and, after much time spent in investigating it, was found to be due to a somewhat similar cause, a near approach to synchronism between the periods of torsional and pendulous vibrations. If the axis of the wire passed accurately through the centre of mass of the vibrator, this would not occur; but this condition it is practically impossible to fulfil. Another source of error lies in the fact that in a wire recently suspended the torsional vibration period will always be found to be slightly greater than when it has been suspended for some time, and frequently oscillated.

"On a Mode of Driving Electric Tuning Forks," by Prof. S. P. THOMPSON. It is invariably found that the frequency of an electrically maintained fork is continually changing. This great inconvenience the author believes to be due to the fact that the impulses are given to the prongs at a disadvantageous moment, namely, when they are at the extremities of their swings. It is desirable that the impulse should be given at the middle of the swing, and to effect this it is suggested that each fork should make and break the circuit of the magnet influencing the other one, and it was shown how the electrical connections could be made to effect this in a simple manner.

"A Further Note on the Formulæ of the Electro Magnet, and of the Dynamo," by Prof. S. P. THOMPSON. In a paper recently communicated by the author it was shown that an expression given by Fröhlich for the intensity of magnetisation in terms of the magnetising force, was nearly identical with one derivable from a simple law enumerated by Lamont. In a recent paper Fröhlich has further developed this law, and in the present paper the author has extended Fröhlich's results and has applied them to the various forms of dynamos.

COMPANIES' MEETINGS & REPORTS.

United Telephone Company (Limited).

The sixth annual ordinary general meeting was held at the City Terminus Hotel, Cannon-street, on the 6th inst., under the presidency of Mr. James Brand.

The SECRETARY (Mr. Thomas Blaikie) read the notice convening the meeting. The report of the Directors has appeared in *The Electrician*.

The CHAIRMAN said: I hope you have had your report soon enough on this occasion. You complained before of not having it soon enough, so we have sent it out a few days earlier. You will have noticed from our report that, so far as our accounts are concerned, we have entirely separated the business of our metropolitan area from the general business of the Company. As regards the capital expenditure, we have spent £143,600 in our metropolitan district, and £43,000 on instruments now in use in the metropolitan district, and by the subsidiary companies. This shows an increase of about £26,000 as compared with last year, and it has resulted in an increase of gross revenue of nearly £20,000, and an increased net revenue of about £11,000. I may say that this net increase would have been somewhat larger, but we thought it right to debit revenue with the whole cost incurred through the snowstorm of January last. I may say that we should have been justified in debiting capital with a good deal of the amount, as while replacing poles and wires that had been damaged, we took the opportunity of making good provision for our increasing business by strengthening our poles and running cables which would tend to diminish the multitude of wires. As to the dividend, we propose to put £10,000 to the reserve fund, and we have already placed £2,700 to the same fund which arose from exceptional profits. The reserve will now, therefore, be about £97,000, and we have also made a provision in excess of maintenance for the depreciation which must always go on in the metropolitan system. As to the working and progress of our business, we have been making great alterations and improvement in our whole system and in all our switch rooms, but notwithstanding this, we have increased our exchanges during the year in the metropolitan district from 19 to 25, our messages over the wires have increased from 15,500,000 to 17,760,000, and our subscribers have increased from 3,820 to 4,393. The National Telephone Company has 49 exchanges, Lancashire and Cheshire 43, Northern District 10, Telephone Company of Ireland 4, Western Counties and South Wales 9, and the South of England 22, giving, with the United Company, a total gross income of nearly £300,000 per annum for the United Kingdom. Besides the additional exchanges we have call rooms at Kilburn, Clapham, Balham, Norwood, Coleman-street, Oxford-court, Chancery-lane, Heddon-street, and the Houses of Parliament; and we are nearly ready for opening stations at the Temple, the Law Courts, Herne Hill, Holloway, and Earl's-court. These do not exactly bring direct profit to the Company, but they help to popularise the business, and will form bases for future exchanges. I am sorry that while we give all these facilities we find people rather slow to avail themselves of these advantages. Habit, you know, is very slow to change. Even the arrangement we made with the General Post Office (as to which we thought ourselves rather clever), whereby subscribers are allowed to speak their telegraphic messages instead of sending them by hand, has been made use of to only a very small extent. Experiments are being made daily by all concerned in long-distance telephony, and I believe that we are approaching within reach of connection by telephone between London and some of our chief ports. We ourselves have spoken to Bristol from Westbourne-park, and I understand that distinct conversation has taken place between Uxbridge and Liverpool. The great difficulty, however, is to get a line of wire clear from the influence of other electrical wires, in which the current is much stronger, and destroys our current by induction. We are continually told that our prices are too high, and that we should get a great increase to our subscribers and over our system if we lowered our rates. We have lowered our rates to a certain extent, and we shall do so when it is advisable. Any £20 business subscriber can now be joined up with his private house for £12. You must, however, remember that every additional subscriber joined up increases the difficulty and the expense of working the system, and it is much better to try and give a perfect service at a reasonable charge than by reducing the cost to get so many subscribers at a low rate as would render our difficulties insurmountable. This is also the experience of the American and Continental exchanges. As at present advised, therefore, we do not think a lowering of the rates would be beneficial. In a small town with a few subscribers to an exchange a lower tariff can be profitably adopted; but when the communication is to thousands instead of hundreds the cost and the complications are immensely increased. In America, where the number of subscribers is very large indeed, many business firms pay an additional sum for being upon separate express systems. The lowest charge in New York is £30 per annum, and in Paris it is £24. Our system is so valuable in consequence of the great number of subscribers who can communicate with one another. Mr. Vaill, the chairman of the Telephone Company of America, says from experience, that the service is divested of half its value the moment half the people become affiliated to another system. We are very sorry we have again to write off a large sum for law expenses; and we had hoped that decisions of previous years would have been sufficient to maintain our patent rights without further litigation; but we are paying the usual penalty of success. So long as money is to be made by it there will be persons ready to convert other people's inventions to their own purposes. Mr. Winterbotham, one of our solicitors, says that Mr. Edison in his patent uses a diaphragm which receives the sound waves from the voice. In a case which we have recently had to go to the Court with, Messrs. Bassano and Slater used a vibrating mouth tube and back board, which

Digitized by Google

served the same purpose, and they contended that this was not an infringement because they used no diaphragm. Mr. Justice North, however, decided last year that it was an infringement, but the defendants, not satisfied with this decision, carried the case to the Court of Appeal, and last Monday that Court unanimously confirmed Mr. Justice North's decision. The worst of it is, unfortunately, that those gentlemen who infringe are not always in a position to pay the penalty of their misdeeds, and as soon as they are asked to pay the costs they take advantage of the Bankruptcy Act ; and though we get decisions in our favour we have to pay our costs, and we can get nothing out of them. It is, however, only by vigorously proceeding against infringers, and insisting upon the delivery up of the infringing instruments wherever found, that it is possible to prevent the wholesale infringement of the Company's patents, and this necessarily involves a considerable expenditure. We must look upon this as a necessary charge to protect our own revenue—like the expenses of the coastguard to prevent smuggling. I understand that we have recovered more than 2,000 infringing instruments from various people, and all of these have been delivered up to our Company. The purchasers lose both the instrument and their purchase-money as a penalty for dealing with those persons who pretended that they were not infringements on our patents. We think we have been able to show you a good account, but if we are to go on and prosper I must say again that the shareholders must assist in helping forward the business, and not only bring in more subscribers to our system, but enable us to put them on as quickly as possible by assisting us to get way-leaves, because although very often we can get subscribers, it takes us a long time to connect them. Every shareholder has some influence over other persons, and a kind word in those cases would very often get us a way-leave which we should otherwise not obtain. Sometimes, I am sorry to say, we have had to ask for some forbearance from our subscribers, who are not satisfied always with the quickness with which the system is worked, and they have recently been kept a long time before getting connected with one another. But I must ask you to remember that during the last three or four months we have completely renewed the interior of two of our largest exchanges, and also one of the great Trunk exchanges ; and all this has had to be done at night time, or during the day time when we cannot cease our business for a single moment. You can therefore imagine the great difficulties we have to surmount. I think, however, that in a month's time we shall be able to show the subscribers a very much improved working of the whole system ; and after that, if it answers, we shall proceed to renew our other exchanges in town and on the same plan. We have got a sort of show now on at two or three of the exchanges—in Queen Victoria-street and Oxford-court—and I wish some of the shareholders would go and get some notion of their property and the way the business is carried on. If subscribers and shareholders would only come and see how the business is done they would be able to estimate for themselves some of the enormous difficulties that have to be met with and overcome in carrying on this telephone system in London. I do not think I have any further remarks to make at present, and therefore I will now move, "That the report and accounts be taken as read, and be received and adopted ; and that a dividend for the half year ended 30th April, 1886, of 9s., less income-tax, for fully paid shares, part paid shares receiving in proportion, be now declared, making a total dividend for the year of 13 per cent. on the paid-up capital of the Company."

The DEPUTY-CHAIRMAN (Mr. J. S. Forbes) formally seconded the motion.

Mr. DONOVAN said the number of subscribers and the private wires, multiplied by 20, showed a discrepancy as compared with the amount stated in the report.

The CHAIRMAN : Do you want to know the amount paid by subscribers to the private wire system ?

Mr. DONOVAN : Including the private wires and the exchange system.

The CHAIRMAN : All the private wires are different prices—all sorts of prices, varying from £5 to £60.

Mr. DONOVAN : That will account for the discrepancy.

The CHAIRMAN : Yes, I think so. Then there are all the £12 wires, which are a good deal taken advantage of for connecting up subscribers with their own houses. Any £20 subscriber may now be connected with his own house, if it is within the metropolitan area, for £12 additional.

Mr. WILLIAM ABBOTT addressed the meeting at some length, and in the course of his remarks said : I think it speaks a great deal for the character of your report that your shareholders upon this occasion receive your remarks without making any comment upon them. It is not my intention to make any adverse criticism on the report, because, if I were so disposed, I must candidly tell you that I could find nothing on which to hang remarks. But, sir, I waited for the issue of this report to see if it was the intention of the Directors to make any movement with regard to the very large dormant asset which you have, and which you retain in your subsidiary shares. I think the time has now arrived when that very important question should be carefully considered. Far be it from me to wish it should be considered by the shareholders in a spirit of hostility to the Board, for that is certainly not my intention—my intentions are quite the reverse ; I wish that it should be considered in the interests of the shareholders, and in the interests of the Company. I lately addressed a letter to the Chairman, suggesting that now was the time when this question should be taken into consideration. It is quite impossible you should keep down your dividend to 13 per cent. This Company is only in it infancy. You have only really scratched the surface of telephone enterprise in London alone, and you certainly have gone very little below the surface in the development of telephone enterprise in the provinces. That being the case, I made a suggestion to the Chairman. I am not going to trouble you with the whole of the letter I addressed to Mr. Brand, but I stated that I saw several advantages in the plan I proposed, one of which was that those £600,000 odd shares of the nominal value of £6. 10s. for every one of your shares should be placed in a trust, the Directors remaining the trustees, and that against those shares they should issue to each shareholder a bonus certificate to bearer of the nominal value of £6. 10s., but of the actual market value of about £4. The reason I made this suggestion was that, in view of the increased dividend which is certain to come to you, it is unfair that those shareholders who have borne all the trials and anxieties with the Directors should not, now that the time has arrived, have taken into consideration such a distribution as I propose, and which I think would not only be feasible, but very acceptable to the members. In this letter I maintain that the new shareholders who come in as fresh partners have no right to participate in those shares. They come in as partners on the dividend-earning power of the Company, and not to share in the accumulations which by the foresight of the Board have been created in your interests alone. Now I say in my letter : "The issue of these 'bonus trust certificates' in such proportion as may be decided upon would not really reduce the value of the original share, as there is every prospect that with the increasing business the dividend will now steadily augment." And now comes the most important point : "The permanent augmentation in value of both classes of shares by the creation of a new proprietary, whose interests would be largely identified in the development of the subsidiary companies." You attached in your opening address great value to that very point. You referred to the widening out of the proprietary, and to the widening out of the subscribers, which bring in an increased revenue to the parent company. I maintain the plan I propose would have that effect—it would largely augment the interest people take in telephone enterprise, which is hardly known and understood. I went down to Wales the other day and there they hardly believe in the possibility of talking at a short distance. If this was thoroughly understood the value to the parent company would be largely increased. Well, another point is, "That the directors being also the trustees, the control of the sub-companies does not pass away from them." That is most important. It would be a very serious matter if these shares of the sub-companies passed into other hands, and if the directors had not the full control of the sub-companies. No doubt Mr. Brand will say that the sub-companies are only in their infancy, and that we should be parting with a valuable asset which has not been properly developed. I will reply to that, "Perfectly true; but while you are going on hatching these golden eggs surely the shareholders may have them in another form. There can be no objection to them having them in the shape of bonus certificates." Now, sir, it may be said, "Why does Mr. Abbott come in and disturb our quiet, peaceful, happy state?" Some of those whom I represent—and I represent shareholders holding 2,000 shares—have an idea that they may as well enjoy the fruit which they have sown during their lifetime, and not leave the enjoyment to posterity. An intelligent countryman of my own, who was not a Home Ruler, said, "Posterity has done nothing for me," and why should we not have the benefit of these subsidiary shares before we throw off this mortal coil? I see that Mr. Forbes is present, and Mr. Forbes knows that exactly a similar thing was done, or is about to be done, in the Metropolitan Railway, who have a certain amount of surplus land in the capital account. There it remained, and its value was not shown in the stock, but a resolution of the shareholders allowed the directors to separate the land from the stock. And what is the result? A considerable advance in the value of the stock. I do not see why you should not enjoy the benefit of a considerable advance in your property, and the divison I propose would have that effect. I am not advocating this for market purposes. You alluded just now to the serious difficulties you have had to surmount. It is perfectly true, and I do believe that you have surmounted them, and I believe now the energies of yourself and the staff will be set free for the development of the property, which, as I say, is only in its infancy. He afterwards referred in warm terms to the services of the Chairman, and alluded to an interesting visit which he had paid to the works, over which he had been conducted by Mr. Morgan (the Managing Director). He trusted that the Chairman in his reply would state whether his (Mr. Abbott's) proposal would have the support or the opposition of the Board.

MR. E. H. GALSWORTHY said he was not convinced by Mr. Abbott's argument in favour of the scheme which he had propounded, and he demurred altogether to the suggestion that the Chairman should state off-hand whether it would receive the support or the opposition of the Board. On the other hand, he considered Mr. Abbott's remarks worthy of grave consideration, and for his own part he would have perfect confidence in the decision at which the Directors might arrive, seeing how they had managed the affairs of the Company up to the present. Mr. Abbott had given as the reason for his proposal that if the shares were divided as he proposed their price would advance. He thought that that was a matter of opinion. He found that the revenue account had this time benefited by the dividends on the subsidiary shares to the extent of £11,200. If Mr. Abbott's plan were adopted the revenue account would lose that, and the dividend would suffer ; and if the dividend were less, the market value of the shares would be depreciated. If he could have the benefit of the same dividend as well as the benefit of the subsidiary shares in the manner foreshadowed, he would be glad, but he did not see how that could be done. He desired to know whether anything fresh had been done in the way of legislation, remarking that the Company had not its own way, and that what it had was very much on sufferance and by the leniency of other people. He certainly could not agree that the anxieties of the Board were over [the Chairman : Hear, hear]. He wished to know, as regards the working expenses, whether provision had been made for depreciation, and whether the expenditure had been taken this year on the same basis as in the preceding year.

The CHAIRMAN, in reply, said that with regard to the progress of the subsidiary companies, they were last year asked for some information on the point ; but there was some difficulty in bringing into the accounts of

Digitized by Google

the Company the accounts of the other companies. The National Company had a gross income of £80,000, the Lancashire and Cheshire Company £73,800, the Northern District Company £4,200, the Irish Company £9,813, the Western Counties Company £10,600. and the South of England Company—which was the last established—£8,400. They had done nothing with regard to legislation. No one had said anything to them, and they had not said anything to anybody. Of course the Directors would do their best with regard to legislation. He quite agreed with what Mr. Galsworthy had said, and no one knew better than that gentleman the difficulties against which the Company had to contend. He by no means expected to have a bed of roses in the future, certainly not in the immediate future. As to the question about depreciation, they had allowed £6,500 on that head, besides the maintenance which was constantly going on. He did not know that he could say any more than that. With regard to the remarks of Mr. Abbott, he did not take exception to anything that that gentleman had said. He might have thought that Mr. Galsworthy, from his remarks, had been present at the interviews which he (the Chairman) had had with Mr. Abbott. The matter was one that would require very careful consideration on the part of the Directors, and he was not quite sure that Mr. Abbott had acted rightly in putting his proposal in his circular. Mr. Abbott had said that he did not think it possible that anyone could accuse him of approaching the Directors in a hostile feeling. He (the Chairman) did not think it possible that Mr. Abbott or any other man could do that. Like Mr. Galsworthy, he (the Chairman) did not know much about Stock Exchange matters, but the principle on which the Directors had gone had been to raise the price of the shares by paying good dividends. He wanted Mr. Abbott, in advocating all the things that appeared to him to be so good in their Company, not to pile it up too much, as they were surrounded by all sorts of people who might take advantage of it. It was the bounden duty of the Directors to think of everything that was to the good of the Company, and if Mr. Abbott at any time would like to come and see him he would tell him if he was getting any nearer to Mr. Abbott's way of thinking. As he had already told Mr. Abbott, "If I can pay £5 dividend, and the price of the share is £100, and you can show me how to transform that £100 into £120, and do no harm to any one, I shall be very pleased, and so will the other Directors, as we all hold a considerable stake in the Company." They had not made up their minds in the matter, but as he had intimated already, whatever was good for the shareholders was good for the Directors. He put the resolution, and it was carried.

On the motion of the CHAIRMAN, seconded by the DEPUTY-CHAIRMAN, the election, by the Directors, of Mr. Dwyer Gray, M.P., as a member of the Board, was confirmed.

Mr. Dillwyn Parish and Mr. W. C. Quilter, M.P., the retiring Directors, were re-elected, as were also the auditors, Messrs. Quilter, Ball, and Co. and Messrs. Price, Waterhouse, and Co.

Mr. W. ABBOTT then proposed, and Mr. GALSWORTHY seconded, a vote of thanks to the Chairman and Directors, Mr. Galsworthy expressing the hope that some day the shareholders would place on some permanent record their appreciation of the services of Mr. Brand, who, he thought, had the United Telephone Company on the brain.

The CHAIRMAN, in acknowledging the vote, assured them that the Directors had all worked hard, and he was only very glad to think that their efforts had had such good results.

The meeting then separated.

West African Telegraph Company (Limited).

The first ordinary general meeting of this Company was held at the offices, 98, Cannon-street, on Friday, the 2nd inst., Sir Fredk. J. Goldsmid in the chair.

The SECRETARY (Mr. R. N. Moir) having read the notice calling the meeting,

The CHAIRMAN said that the statement of accounts submitted was of a *pro forma* character—to meet the requirements of the Company's Articles of Association—and the items did not appear to require explanation. The prospectus of the Company was not issued until the 8th of April last, but a considerable amount of work had been done previously to that date. In order to comply with the conditions of the concessions, it was necessary that the first sections of the cable should be completed within six months. Accordingly by the 5th December, the cables between Senegal, Bolama, Bissao, and Conakry were laid, and in the same month opened to the public. This fact was practically important, because from this particular period the Company was entitled to such portions of the Portuguese guarantee as might be applicable to those sections, and also to the French subsidy for Conakry. Since the issue of the prospectus much progress had been made in carrying out the work contemplated. The contractors' cable steamers, "Dacia" and "Buccaneer" left the Thames on the 22nd May, and information had already been received informing the Directors that communication had been established with Bathurst, and a station opened there. They had also pleasure in reporting that the cable between Conakry and Sierra Leone was successfully laid and communication opened on the 30th ult. Up to the present time the Directors had every reason to be satisfied with the manner in which the contractors were fulfilling their contract, and it was expected that the Company's system would be completed to St. Paul de Loanda by the middle of October, or some two months before the period required by their Portuguese and French concessions. The Directors had also to report that since the issue of the prospectus they had entered into a working agreement with the African Direct Telegraph Company, which gave very favourable transit rates to the West African Company, and the permission to land at the English colonies enabled this Company to compete with the African Direct Company on equal terms for the traffic of those stations. He concluded by moving the adoption of the accounts to the 31st December as presented, and the motion having been seconded, it was carried unanimously.

Eastern Telegraph Company.

Report and accounts of the Directors for the half year ended 31st March, 1886, to be presented to the twenty-eighth half-yearly ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 15th inst., at one o'clock.

The revenue for the period amounted to £341,405. 8s. 10d., from which are deducted £92,244. 15s. 10d. for the ordinary expenses, and £41,637 3s. 2d. for expenditure relating to repairs and renewals of cables, &c., during the half year. After providing £3,940. 4s. 11d. for income tax, there remains a balance of £203,583. 4s. 11d. to which is added £32,549 12s. 5d. brought from the preceding half year, making a total available balance of £236,132. 17s. 4d. From this balance there has been paid—

Interest on debentures and debenture stock	£27,756	17	10
Dividend on Preference shares	20,296	16	10
An interim dividend of 1¼ per cent. on the ordinary shares	47,500	0	0
	£95,553	14	8

leaving a balance of £140,579. 2s. 8d., from which £70,000 has been carried to general reserve. The Directors now recommend the declaration of a final dividend for the year ended 31st March, 1886, of 2s. 6d. per share and a bonus of 1s. per share, amounting to £66,500, both payable on the 15th inst., making, with the three previous payments on account, a total distribution of 12s. per share, or 6 per cent. for the year on the ordinary shares. The balance of £4,079 2s. 8d. shown at the foot of the revenue account is proposed to be carried forward to the next half year. The revenue includes £9,750 dividend for the half year upon the Company's shares in the Eastern and South African Telegraph Company. Also £2,600 net receipts for the same period on the shares of the Black Sea Telegraph Company belonging to this Company. The receipts of this half year compare with those of a period when the income was abnormally increased by the telegrams resulting from the military operations in the East, and they have also been adversely affected by the continued commercial depression. The reductions in the tariffs agreed to at the International Telegraph Conference in Berlin in 1885 came into operation on the 1st inst., but it is as yet too early to form an estimate of the probable effect on the Company's revenue. The several sections of the Company's cables and the land lines in connection therewith are in good working order, with the exception of the Direct Lisbon cable, which is now under repair by the Company's ss. "Electra." Since the last general meeting the arrangements with Her Majesty's Government for establishing telegraphic communication with the British possessions on the West Coast of Africa have been completed, and the work is now being carried out by the African Direct Telegraph Company. The subscription by this Company of £75,000, being one-third of the share capital of the African Direct Telegraph Company, approved by the last meeting of shareholders, has been effected by the issue of a similar amount of 4 per cent. debenture stock of this Company.

NOTES.

CABLE INTERRUPTION.—The cable between Antofagasta and Caldera is interrupted.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 9th inst. amounted to £3,136.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending June 30th were £3,200.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY. A half-yearly general meeting of this company will be held at 38, Old Broad-street, E.C., on Tuesday, the 20th inst., at 1 o'clock.

BRIDGE BUILDING BY THE ELECTRIC LIGHT.—The cylinders of the bridge of six 130ft. spans, over the Beypore River, on the Beypore-Calicut extension, are being sunk at night with the aid of the electric light.

PERSONAL.—In recognition of the great advance exhibited in Mr. Lucius J. Phelps's method of communicating telegraphically with moving trains, the Franklin Institute has awarded to that gentleman the John Scott medal and prize.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 9th inst., were £2,451, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

TELEPHONIC EXTENSION.—The Northern District Telephone Company have received permission from the Durham and Chester-le-Street Highway Board to erect 50 telephone poles on the roads between the top of Crossgate, Durham, and Aldin Grange.

PERSONAL.—Mr. Hugh Watt, M.P., managing-director of the Maxim-Weston Company, has had conferred upon him by the President the Grand Cross of the Order of Simon Bolivar, for distinguished commercial services in connection with the United States of Venezuela.

A HEAVY FINE.—The New York jury, in the action brought by the Receiver of the Bankers' and Merchants' Telegraph Company against the Western Union Railroad Company for cutting the wires of the former, have given a verdict against the Western Union for 240,000 dollars.

OBITUARY.—David van Nostrand, the well-known American publisher, died at his residence in West Twentieth-street, New York, on June 14th last. The cause of death was severe dyspepsia. Mr. Van Nostrand was the most extensive publisher and dealer in electrical works in America.

POSTAL TELEGRAPH REVENUE.—The exchequer returns for the period from April 1st to July 10th of the present year show that the total receipts from the Telegraph Service were £425,000, a falling off of £20,000 as compared with the corresponding period of 1885, when the 1s. tariff prevailed.

HONOUR TO ELECTRICIANS.—M. Eugène Sartioux, chief of the telegraph service of the Northern Railway Company of France, and M. Henry Vivarez, civil engineer of mines, and an old and distinguished student of the Ecole Polytechnique, have recently been made knights of the Legion of Honour.

BRUSH ELECTRIC LIGHT CORPORATION.—The Brush Company is giving notice by circular that they are prepared to indemnify all users of their incandescent electric lamp, known as the "Victoria" lamp, against proceedings for any alleged infringement in those lamps of the patent rights of other manufacturers.

ACCIDENTS FROM LIGHTNING.—In a lecture given by Captain Holthof before the Physical Society of Frankfort-on-the-Main, the lecturer pointed out that accidents by lightning stroke had become more frequent since the trees had been so largely cut down, and the houses fitted up with electrical wires, gas fittings, and metal roofs.

ELECTRIC LIGHT COMPANIES.—The shareholders of some of the electric light companies in America are better off than their colleagues here. We notice, for example, that the Hartford Electric Light Company, using the Thomson-Houston system, has been paying a dividend of 1½ per cent. regularly each quarter for the last year and a half.

ELECTRIC LIGHTING AT KETTERING.—Messrs E. L. Berry and Co., of Oxenden-street, W., made a successful installation of the electric light at the Corn Exchange, Kettering, on July 4th and 5th, and also at a *fête* held in the Rectory Grounds on the 6th, 7th, and 8th inst. Messrs. Goolden and Trotter's Tallenta arc lamps were used, together with about eighty coloured incandescent lamps.

SIMPLICITY OF WORKING ELECTRIC TRAMWAYS.—Mr. Holroyd Smith, consulting engineer to the Blackpool Electric Tramway, writing to a local newspaper, says :—"I am thankful to say that my professional services are seldom required, for the problems I had to solve have been reduced to such simplicity that others previously unacquainted with mechanical science can now undertake the arrangements."

COLONIAL TELEGRAPHS.—Conformably with our announcement in last week's edition, Mr. James Sivewright, C.M.G., read a paper on Thursday afternoon last at the Indian and Colonial Exhibition on the subject of our colonial telegraph system. The same paper, we understand, will with certain additions be read soon before the Society of Arts, when we hope to be able to furnish our readers with a full report of it.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.—A half-yearly general meeting of this company will be held at the Cannon-street Hotel on Tuesday, the 20th inst., at 12 o'clock noon, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax. The directors give notice that the share register will be closed from the 13th to the 21st inst, both days included.

DIRECT UNITED STATES CABLE COMPANY.—The Board of Directors of this Company has resolved to recommend a final dividend of 2s. per share, free of income-tax, such dividend to be payable on and after the 24th inst., making, with the interim dividends already paid, 2¾ per cent. for the year ending 30th June last, carrying forward £3,050. 19s. 3d., after having increased the reserve fund to £325,000. The company give notice that the transfer books will be closed from the 9th to the 23rd inst., both days inclusive.

BRANDING BY ELECTRICITY.—It is said that the Chemical Electric Light and Power Company of Boston have received an order for their Volta-Pavia battery to be put to a new and unique use. The proprietor of an extensive sheep ranche in Montana intends using the battery for maintaining a platinum wire at white heat, which will be used for branding the members of his flock on the nose. The operation is quickly performed, and comparatively painless when the former plan of using a branding iron is considered. An 8-cell battery will be required.

THE ELECTRIC LIGHT AT HANLEY.—The corporation of Hanley are just now experimenting with the electric light, with a view to its adoption for public lighting. So far the majority of the members of the council have expressed unqualified approval of the new system of illumination. The small installation, which is purely arc light, of course has been

Digitized by Google

put up in the covered market, and there is reason to believe that, as the result of the experiments, a contract will be entered into for permanently lighting the town by electricity.

HOME RULE IN FRANCE.—M. Granet, Minister of Posts and Telegraphs, has concluded a contract with the Messageries Maritimes Company, by the terms of which the company's present steamship services are to be modified, and additional services are to be established. It is specially stipulated that the company's vessels shall be of French construction and use French coal, and also that the transport tariff shall no longer benefit British products to the detriment of French merchandise. The new contract will come into force at the end of 1888.

AN EYE TO THE FUTURE.—In view of the celebration of Her Majesty's jubilee, the gas companies are showing unusual activity, and are industriously circulating, for the information of all those whom it may concern, certain hints and instructions on the subject of outdoor illuminations. This gratuitous and timely advice, it is needless to say, conclusively proves, from the gas companies' point of view, the superiority and economy of coal gas for these purposes as compared with electricity. Whether the public will be of the same opinion the future alone will determine.

ILLUMINATING WATER BY ELECTRICITY.—At the new Cirque Nautique in Paris there is just now an aquatic performance of a very novel character. After the conclusion of the ordinary gymnastic and riding entertainment, the carpet is removed from the floor of the ring, and the latter entirely submerged. A circular basin is thereby produced, and an electric arc lamp illuminates the water from below. The swimming performers appear like mermen and mermaids in the translucent depths of the sea. The installation throughout the building is a very fine one, including both arc and incandescent lamps, the *lampe soleil*, or sun lamp, especially producing a most beautiful effect.

THE ELECTRIC LIGHT AT NORWICH.—The offices of the *Eastern Daily Press* have recently been lighted by the electric light. The installation, which has been effected by the well-known local firm, Messrs. Paris and Scott, consists of a hundred lights conveniently arranged throughout the building, the current being supplied by one of their patented four-pole machines. It is needless to say that the compositors and others whom the exigencies of journalism compel to be at work through the greater part of the night appreciate the reduction of heat and the greater purity of the air consequent on the substitution of electricity for gas, not to mention the increased illumination which they acquire by the change.

A NEW CABLE.—The *Echo* of last evening is responsible for the following :—"One link is still wanting to complete the chain of British rail and cable round the world. No cable has yet been laid from British Columbia to our Eastern possessions. It is now announced, however, that a strong syndicate has been formed for joining Vancouver and Hong Kong by cable, and Mr. Sandford Fleming is now on his way to London from Montreal to confer with the Home Government and the colonial agents as to the amount of annual subsidy they would guarantee. It is also proposed to lay a cable from Vancouver to Sydney, but as the distance to Hong Kong is considerably less, being only 6,180 miles, this work will doubtless be undertaken first."

NEW ZEALAND.—The Town Council of Queensland, New Zealand, have rejected an offer to supply the town with gas, thinking that more effectual means of lighting the town by electricity might be devised before long. That electric lighting is making its way in New Zealand is pretty certain. We notice that a temporary installation was put up at an entertainment to obtain funds for the hospital at Skippers Reefs. The correspondent writes:—"The hall was tastefully decorated and brilliantly lighted up with the famous electric light. The attendance was something to be wondered at for these parts, and the catering excellent, so that to call it a great success is very mild praise ; and as to the financial aspect, the result ought to make the Wakatipu Hospital Committee smile for the next twelve months."

NEW PRIMARY BATTERY.—Dr. S. T. Stein, of Frankfort-on-the-Main, considers that the best battery for curative purposes would be one in which the exciting liquid does not evaporate, so that no salts are formed on the upper edge of the jar. Many attempts have been made to secure this desideratum, but hitherto without success. Dr. Stein has, however, conceived the idea of adding gelatine to manganese batteries, finally adopting a mixture of gelatine, glycerine, sal ammoniac, and salicylic acid, the electrodes consisting of a carbon cylinder, with bioxide of manganese for the positive pole, and a zinc pencil for the negative pole. The internal resistance is, according to size, from $\frac{1}{2}$ to $\frac{1}{8}$ ohm, and the E.M.F. from 1 to 1·085 volt. The chemical reactions of the new battery are the same as in the Leclanché.

A USEFUL INVENTION. — An ingenious apparatus has recently been invented by M. Helie which ought to command some attention on the part of railway companies. This is a simple mechanical appliance which apprises the guard in charge of a train in motion whenever a carriage door is opened, by letting on an electric current which sounds an alarm bell, when of course he can immediately communicate with the driver and bring the train to a stop. In these days, when crimes are not infrequent on railways in all parts of the world, the universal adoption of such an arrangement would afford an additional sense of security to the traveller, for the would-be perpetrators of such deeds as those of Müller and Lefroy would then have to think twice before indulging in their merciless work of rapine and murder.

TODMORDEN AND THE ELECTRIC LIGHT.—There is at last some hope of the inhabitants of Todmorden being served with an installation of the electric light. It would appear to have been the custom of the Local Board to appoint annually an electric lighting committee, whose duty was supposed to be to take some practical steps towards meeting the wishes of the ratepayers in the matter of public lighting by electricity. Up to the present time, however, those committees seem to have folded their hands and gone to sleep. We are glad to see that the gentlemen who have been last delegated to look after this important department of the local polity have taken the initiative step of inviting the Victoria Electric Lighting Company to furnish the Board with some information as to its mode and cost of lighting. It is to be hoped that, as the result of the negotiations, the electric light will soon be permanently installed in the streets of Todmorden.

ELECTRIC RAILROADS.—We have received from the Daft Electric Light Company a small pamphlet describing the Daft Electric railways as used at Baltimore. The report of the manager of the railway company states that from September, 1884, to May 20, 1885, using three cars with horses, a total number of 158,684 passengers was carried at a cost per passenger of 3·01 cents. From September, 1885, to May 20, 1886, that is during the corresponding period twelve months later, working two cars with Daft electromotors at a speed almost double that when two horses were used, the total number of passengers carried was 188,591, at a cost per passenger of 1·66 cent. The total cost per day was 12 dollars, as against 18 dollars

Digitized by Google

per day for the horse. The length of road is nearly two miles, or more exactly 10,080 feet. The total weight of the train with 50 passengers is about 17,250lbs.; the usual service of the motors is about 73 miles per day.

CRYSTAL PALACE.—The Gülcher Company have extended the electric lighting to the illumination of the grounds of the Crystal Palace, which gives great satisfaction. The installation consists of eighteen arc lamps, seventeen of 2,000 candle-power and one of 3,000 candle-power. Six of 2,000 candle-power are used for lighting the Rosary, and four of 2,000 candle-power in the band stand. The remaining seven, of 2,000 candle-power, are placed in different positions for the general illumination of the grounds, the 3,000 candle-power lamp being placed on a high pole for lighting the large centre lawn. The general effect is extremely pleasing. The lamps are driven by two No. 4 Gülcher dynamos, the current being taken to a double switch-board, which is arranged so that in case of accident to any dynamo the whole of the lamps may be worked from the one dynamo. The machines are driven by two of Messrs. Ransomes' 10 horse-power portable engines.

TEMPORARY LIGHTING.—The Gülcher Company are lighting the new building belonging to Messrs. Allen and Sons, builders, for the Temperance Mission now being held at Kilburn. The installation consists of forty 20 candle-power incandescent lamps for the illumination of the large room where meetings are held nightly. The incandescent lamps are suspended from the ceiling by flexible pendants, which carry an ornamental shade, and the general effect is extremely pleasing, and great satisfaction has been expressed by the members. In addition to the incandescent lamps, three arc lamps of 2,000 candle-power are employed for the illumination of the Palmerston-road, and the entrance to the building. The current for driving the installation is generated by a No. 4 Gülcher dynamo machine, and the motive power is obtained from Messrs. Allen and Son's saw mill engine. Only two days' notice were given to carry out the installation, and therefore its successful accomplishment reflects great credit upon the contractors.

INTERNATIONAL WIRE GAUGE.—Our contemporary *The Electrical World* is giving space for a correspondence suggesting the advisability of an international wire gauge. We should strongly support any suggestions in this direction, as we think that the best interests of commerce are furthered when in ordering every one can quote similarly. It may be that it is in the interest of one particular firm, or the interest of a few firms, to support different gauges, in that a firm which has made a reputation for wire would prefer to keep all its customers. We are quite sure that the business of a firm does not ultimately depend upon the minute difference which it makes in its sizes, but in the quality of the material it sends to its customers, and to the method adopted in treating with those customers We believe the suggestion of an international wire gauge is on a par with suggestions which recommend international gauges for screws, international coinage, &c. It might be of some assistance to our American brethren if expressions of opinion were given on this side of the Atlantic.

PHOTOMETRY.—The first portion of what would seem to be an excellent article upon "Photometric Measurements, and their Relation to the Efficiency of Incandescent Lamps" appears in the issue of the *Electrical World* for July 3, just received. The article is written by Mr. A. P. Wright, who, at the commencement of the article, says:—"To compare the relative efficiency of incandescent lamps it is not merely sufficient that the electrical measurements should be made with accuracy, but the measurement also of their illuminative intensity should be estimated with precision. While great care is usually taken to insure the accuracy of the electrical measurements, the photometric observations are frequently as crude as the instruments with which they are too often made. Again, while these measurements, when carefully conducted with a good photometer, give results which show the relative illumination of lamps having filaments of the same configuration and dimensions, they in almost all instances fail in showing either the true mean illumination or the relative lighting value of filaments of varying form, length, and section."

ELECTRIC GONGS ON GERMAN RAILROADS.—Tabulated statements of the number of electric gongs by which the approach of the train is announced from point to point, especially at crossings, on German railroads, make, says the *Railroad Gazette*, the mean distance apart of these gongs 950 metres, or 3,116ft., and on Austrian railroads 1·04 kilometres, or 3,411ft. These gongs are arranged on a circuit between two stations and are operated analogously to the block system; that is, station A announces to B that a train is ready to start, whereupon, if B knows of no obstacle, he acknowledges the signal by giving "all right," and A then presses the key which causes the gongs between A and B to strike. The German roads are now generally arranged so that this system is a perfect block, telegraph stations being inserted where necessary between the stopping stations; but on the light traffic roads B is allowed to give "all right" without having received the last train that went into the block. It will be perceived that even where not used as a block system, and apart from the warning given to trackmen and crossing tenders, these bells, which can be heard nearly, if not quite, from one end to another, are a considerable aid to safe working, since a train in the block always gets warning of another train entering behind it. These bells are used by combinations of blows to give a variety of information, such as "Train toward A!" "Send over engine!" "Stop all trains!" "Set your watches—noon!" "Train backing up on wrong track!"

INTERNATIONAL SOCIETY OF ELECTRICIANS.—At last this society seems to have got a local habitation and a name. An extraordinary general meeting was held this week in Paris for the purpose of giving effect to a generally-expressed desire on the part of the gentlemen forming the association, which hitherto has been only a nominal one, that they should have a corporate *locus standi*. The effect of this will, of course, be to increase the society's powers of action and usefulness, and to enable it to carry out those projects which have already been formed by its irresponsible members. In the course of the sitting the President announced that the difficulties which have militated against the establishment of a central electrical laboratory—a project which has been in a state of incubation since the Exhibition of 1881—have been almost overcome. Thanks to the good offices of the present Minister of Ports and Telegraphs, the stupid obstacles which were put in their way by the previous administration, &c., had all but disappeared, and the sum of 325,000 francs which had been at their disposal for more than four years will now be put to the uses for which it was originally destined. M. Maurice Lœwy has, indeed, gone so far as to inform his colleagues that 31,000 francs will be immediately spent in the name of the society in the purchase of its first apparatus. The Executive Committee, in their desire to give to the Minister an earnest of their gratitude for his courtesy and kindness, have placed the society under his immediate protec-

tion and patronage by their intention of holding their reunions henceforward at the offices of his department.

FARBAKY AND SCHENEK'S ACCUMULATOR.—In this new secondary battery the lead plates are covered in a special manner without being subjected to great pressure, and with an active substance specially prepared, the object being to obtain a more energetic and constant action, and to prevent the active substance from escaping at the interstices of the plates. The thickness of the plates and the nature of their "making" differ for the positive and negative electrode, the former being from 10 to 12 millimetres thick, and the latter from 6 to 8 millimetres. The active substance for the negative plates consists of 95 parts by weight of well powdered litharge, without copper, and 5 parts of pumicestone, in grains of 1 to 1½ millimetres, for rendering the mass less dense and more porous. This condition is very important, because it facilitates the escape of the dilute sulphuric acid, and consequently the working of the accumulator. The two substances are intimately mixed in the open air, or in a well-ventilated room, and then diluted sulphuric acid (at 25 per cent.), free from arsenic, is added to form a granular mass, rather damp to the touch. The active substance for the positive plates consists of 95 parts by weight of litharge, 95 of red lead, and 10 parts of coke broken into pieces of 1 to 1½ millimetres. The addition of the coke is for rendering the substance more conductive, and also less dense, so as to be more permeable by the sulphuric acid solution. The active substances are spread by a galvanised iron spatula over both sides of the positive and negative plates (which are cast or pressed with interstices) in such a way as to project about 3 or 4 millimetres beyond the surface of the plates. They are then beaten with a flat brass rule, until moisture ceases to exude. That portion which projects beyond the plate is then pared off with a flat knife, and the "made" plate allowed to dry for two or three days, after which they are immersed three separate times in diluted sulphuric acid, and dried after each immersion, and then left in the bath for 10 or 12 hours, and then again dried, when the surface solidifies.

TELEGRAPHIC REFORM.—In answer to some comments in *The Times* on the paper on "Telegraph Reform," recently read by him before the Congress of Chambers of Commerce at South Kensington, Sir James Anderson sends the following letter to the Editor:—"Sir: In one of your leading articles this day I am assumed to have threatened to still further raise the telegraph tariffs. I should feel obliged if you would allow me to say that nothing is further from my thoughts, nor do I know any one who is contemplating such a change, unless it may be that if the present unremunerative Atlantic tariff should fail to develop a paying traffic then something more than 6d. per word to America may have to be charged. In my paper I tried to give several illustrations of plans by which tariffs might be very much reduced. The first and only illustration noticed in your leader showed that if the Government and colonies interested would risk the loss of £1,000,000 per annum for a few years the tariffs to India, Australia, the Cape, South America, &c., might be reduced one-half—that to America and Egypt to be 1s. per word, and I give it now as my individual opinion that this amount estimated for the first year at one million would be a diminishing quantity and cease altogether within a very few years. Private companies cannot in justice to their shareholders make this certain loss over a number of years. I next called attention to the abuse of code by compilers making syllabic combinations to look like words—not satisfied with the eight languages authorised by the Telegraph Convention, and which are said to give 150,000 telegraph words to which we make no objection. I think we should not have the trouble of rejecting illegitimate words, and that sooner or later codes so compiled will be found to be useless, or if commerce will have them the telegraphic conferences of the future may have to consider a letter tariff. The next point of my paper said all that I think can be usefully said as to the neutralisation of cables, their protection in time of war, and the principles which should govern the extension of submarine telegraphy. I did not make any proposition, but said what I could in the brief space of time allowed—viz., twenty minutes—upon the points named by the Chamber of Commerce with the object of opening a full discussion; and, when replying, I ventured to say in effect that this comparatively new force, by which we can in a few hours communicate with the remotest parts of this Empire and the world, will have as much to do with practical federation as the post or steamships. A really great step would be gained in the interests of commerce if the cost of telegraphing could be reduced to an amount of relatively small importance."

CHICAGO.—The following, from our American contemporary and namesake, will show that our cousins are in earnest about overhead wires. We shall be surprised if the action at Chicago is not speedily followed by all the most important cities in America:—"The streets of Chicago are beginning to change in appearance—for the better. The poles and lines are disappearing quite rapidly. The city's wires have been gradually taken in and sent below, until the south side lines, comprising some thirty-five miles of city wires, have disappeared from the lake to the south branch, and from the river to Van Buren-street; and there was not a street in that entire district that had not one or more fire alarm, police, or other city wires. The Western Union people have removed the poles on Lasalle, from Washington to Jackson, on the west side of the street. These were 55ft. high, and were so thickly strung with line wires that they fairly cast a shadow upon the walk. A heavy line of poles on the east of State-street has been removed. To the north of the office at Lasalle and Washington the company will lay a conduit pipe, and reach the tunnel, when the poles along this route will disappear. In short, the Western Union will very soon clean up through all streets in the south division north of 12th Street. The largest poles in the city were those of the Mutual Union Company, from 12th Street, running to the corner of Lasalle and Washington. These ranged from 55 to 90ft., and are all down. The Baltimore and Ohio are preparing to remove everything north of Harrison-street in a few days. The telephone company has arranged to put its wires underground on the following routes at once:—Starting at Calhoun-place on Lasalle, north to Washington, east to Dearborn, south to Jackson, and east to the Alley, south on the Alley to 20th Street, east to the Alley near Michagan-avenue, and south to 22nd Street. This will pretty much clean up the Telephone Company's wires on the south side. On the west side, commencing at Green-street on Madison, the pole lines will be removed to Ashland-avenue; thence north to the Alley, which will greatly relieve that portion of the city. The Mutual Union has also made arrangements for conduits on Lasalle from Washington to Lake, and along this latter street from Fifth-avenue to Michigan-avenue, with lateral crossings north of Randolph, west of Dearborn, and east of Michigan-avenue. To an old resident the aspect of the business portion of the city is, to say the least, peculiar. The streets look wider, the view is less interrupted, and it really does appear lighter, and, while it is claimed by some that the place is stripped of some of its city characteristics, it is hardly to be believed that the day is approaching when a bell ringer will daily call the denizens of the place to come and weed the thoroughfares."

TRANSMISSION OF POWER.—The *Lake Wakatipu Mail* of May 14th, sent us by a correspondent, gives a long account of an electric installation for the transmission of power at the Phœnix Company's gold mine at Skippers Creek, Upper Shotover, Otago. From this account and our correspondent's notes the following description is obtained :—" Transmission by means of wire ropes, compressed air, and electricity were considered, and after a thorough investigation electricity was the only method that could be economically and profitably employed. When it became publicly known that electricity was to be employed for driving the machinery about the mine, Mr. Bullen (the proprietor) and Mr. Evans were looked upon by many of their friends as misguided enthusiasts. Many mines are lying idle a portion of the year through want of power to crush the quartz and for other purposes. Water power there is in abundance, in most cases within two or three miles, and now that the Phœnix Company have shown that electricity can be successfully applied in utilising distant water powers, we may expect to hear of many other companies following their example. Having decided upon the use of electricity, Mr. Bullen and Mr. Evans discussed the matter over with Mr. Prince (electrician), with the result that Messrs. R. E. Fletcher and Co., electrical engineers and contractors, Dunedin, were instructed to supply and erect the necessary apparatus for working a battery of twenty stamp heads. Messrs. Fletcher and Co. determined to leave nothing undone that would secure the complete success of this, the first instance of the electrical transmission of power, on a practical scale, in the southern hemisphere. The choice of suitable dynamo machines for generating the electric power was not a very difficult matter, but the construction of an 'electric motor' capable of exerting a force of from 20 to 25 horse-power was quite a different thing. Acting under the advice of some of the best experts in the old country, Messrs. Fletcher and Co. decided to use a specially-constructed 'Victoria' dynamo machine as the 'motor,' and two large 'Brush' dynamo machines for the 'generators.' It was by no means an easy matter to get the plant up from Queenstown to the mine, a distance of 26 miles, the last six miles being through the creek, which had to be crossed and recrossed no less than 84 times, the Phœnix Company having to do this at their own risk. After several delays due to accidents Mr. Fletcher finished the work, but was not destined to have all smooth sailing, as several faults developed themselves in the motor and generators, caused through injuries received in transit. The house where the electric generators are placed is situated about two miles up the Lefthand branch of Skippers Creek, and is an iron building, 60ft. by 20ft. It is built at the base of a nearly perpendicular cliff, some 200ft. or more in height. An open ground race half a mile in length brings the water from the creek to the top of the cliff, where an almost perpendicular fall of 180ft. is obtained, the water being conveyed down the face of the cliff by two wrought iron pipes 22in. in diameter at the top, tapering down to 6in. at the bottom. The supply of water from this race is equal to ten heads when at its lowest limit, but much more can be obtained when the creek is in its normal condition. The electric apparatus is only using four or five heads at present, so that there is ample power for future extensions. Two Pelton water wheels drive the generators. These wheels are extremely simple in construction, consisting merely of a cast-iron pulley or fly-wheel six feet in diameter, and six or eight inches in width, having a number of square-shaped buckets fixed around its periphery. A nozzle 2½ inches in diameter throws a powerful jet of water into these buckets, causing the wheel to make about 370 revolutions per minute when working at its full power. Each wheel will exert 50 horse-power if required, but at present they are working at much less. Messrs. A. and G. Price, of the Thames, the makers, claim an efficiency of from 80 to 86 per cent. The shaft of each wheel carries a driving pulley, which drives by means of a belt an intermediate shaft; these shafts in their turn carry the pulleys that drive the generators. The whole of the machinery is secured to heavy timber foundations. The electric generators are two of the well-known Brush 40 lighters. They are driven at a speed of from 700 to 800 revolutions per minute, and generate each a current of 10 amperes, having an electromotive force or pressure of 2,000 volts, which is equal to a little over 26 horse-power, or about 53 for the two machines. The two generators are coupled parallel. The current goes to a switch-board, and an ammeter is in circuit. Link-belting is used. These belts are very strong, but at the same time extremely flexible, and do not, like many ordinary leather belts, stretch unevenly. The current is conveyed from the generating station to the battery house by a No. 8 B.W.G. copper wire (the size of an ordinary fencing wire), and after doing its work there returns by a similar wire to the generating station again. These two wires (nearly three miles in length) are supported on poles in just the same manner as a telegraph or telephone wire is, and are brought over a hill about 800ft. in height. Lightning arresters, similar to those used for telegraphs, are attached to each end of the wires, to protect the generators and motor in case of a storm occurring and the lightning striking one of the poles or wires. The power lost on the 'line' only amounts to 3 horse-power, and could be still further reduced by using wires of larger sectional area. A telephone connects the generator station with the battery house, so that the attendants in charge of the generators and the motor can communicate with each other when necessary. The motor, as already mentioned, is a specially constructed Victoria dynamo machine, and when working under its normal condition makes about 350 revolutions per minute. A pulley on the armature shaft transmits the motion by means of a belt to the cam shaft of the battery. By means of a switch, more or less electricity can be sent through the motor, so that the power exerted can be regulated to a nicety. When the motor is stopped for any purpose, and it is not necessary to stop the generators, the current is switched or cut off from the motor and sent through a long series of coils of iron wire. The energy of the current is thereby used up in heating the iron wire instead of working the motor. The average weight of these stamp heads is eight hundredweight. Not the slightest difficulty is experienced in starting or stopping the battery; it starts very easily, and can, if desired, be stopped almost instantaneously. It has not been found necessary to have any experienced hands to work the plant, there being a man told off in each shift to take charge of the motor and battery, no one else, of course, being allowed to meddle with the apparatus in any way. In conclusion, the success of the whole undertaking (which is unique in its way, as it furnishes a remarkable instance of high-pressure electric power) may be fairly said to have been accomplished—in fact, to use the words of the manager, Mr. F. Evans, who has just spoken to us, 'the machinery is working beautifully, and the power is sufficient at the present time to keep going at least five and probably ten more stamp heads.' The importance of this new application of electric power for the lighting and complete working of an extensive mine like that of the Phœnix, opens up a new era in the economic development of the very valuable and unexhaustible mineral resources of the Wakatipu and other goldfields similarly situated, which are by no means suffering from a want of water power, but rather from the means of transmitting that power hither and thither."

ALTERNATING AND INDUCED ELECTROMOTIVE FORCES.—II.

BY W. H. SNELL.

Hitherto we have had under consideration the case of an alternating electromotive force, generated by the rotation of a single loop of wire placed in a uniform magnetic field, and we have taken T as the time occupied in one complete revolution. But in the majority of practical machines for producing alternating currents, the field is complex, and the armature consists not of one coil but of a number of coils set around the circumference of a circle, and these are carried successively through a series of magnetic fields in which the lines of force run alternately in opposite directions. In this case the current in any one coil undergoes one complete alternation during the time which it takes to pass from the centre of one field to the centre of the next field but one. It will, therefore, be evident that the form of the curve which represents the rise and fall of the electromotive force will depend in part upon the shape of the poles of the field magnets and upon the distance between the centres of the successive fields. It might, therefore, easily happen that the curve belonging to a machine of this construction might be quite different from a sinusoid. In the case of the Siemens machine, Prof. Silvanus Thompson states in his book on "Dynamo Electric Machinery" (second edition, p. 332), that it "follows the sine law fairly well." This statement seems also to be supported by the authority of Joubert, but upon the other hand, in the discussion on Dr. Hopkinson's paper on "Alternating Machines," read before the Society of Telegraph-Engineers in 1884, Mr. H. E. Harrison stated that the results of some experiments which he had made proved that "the curve of true sines lies wholly within the curve of the machine."

If, however, we assume that the sine curve is a sufficiently close approximation for the Siemens dynamo, then, in order to adapt the previous formulæ for use with this machine, we have only to take T as representing, not the period of one revolution, but the period of one complete alternation. The expression for θ will then remain the same as before, namely,

$$\theta = 2\pi \frac{t}{T};$$

but its definition will be altered in accordance with the new meaning attached to the symbol T. With these changes all the formulæ already obtained, and (unless the contrary is stated) all that follow, may at once be applied to machines of this class. Having stated this we shall now return, for the sake of simplicity in the theory, to the case of a simple armature rotating in a uniform and simple field.

Before proceeding, however, I should like to take this opportunity to make a small suggestion. Would it not be well to establish the convention that the symbol for a continuous current shall always be C, and that I should be reserved for alternating currents?

Let us now proceed with the subject. It will be useful to have an expression for the current which would be due to the electromotive force of self-induction if that were acting alone. We shall then be able to express the actual current as the sum of the two hypothetical currents due respectively to the impressed and the self-induced electromotive forces.

We have already seen that the E.M.F. of self-induction is given by the equation

$$E_2 = -\frac{d\,L\,I}{d\,t}$$

If we write I″ for the current due to E_2 and divide both sides by R (L being a constant) we have

$$I'' = -\frac{L}{R}\,\frac{d\,I}{d\,t}$$

Substituting for I from (9) this becomes

$$I'' = -\frac{L}{R}\cdot\frac{d}{dt}\cdot\frac{2\pi N}{RT}\cdot\frac{\sin\theta - a\cos\theta}{1+a^2}$$

that is

$$I'' = -\frac{2\pi N}{RT}\cdot\frac{a(\cos\theta + a\sin\theta)}{1+a^2} \quad . \quad . \quad . \quad . \quad (11)$$

Writing a in full, and making a similar transformation to that employed for I, we find

$$I'' = -\frac{4\pi^2 N L}{R^2 T^2}\cdot\frac{\cos(\theta-\phi)}{\sqrt{1+\left(\frac{2\pi L}{RT}\right)^2}} \quad . \quad . \quad . \quad (11a)$$

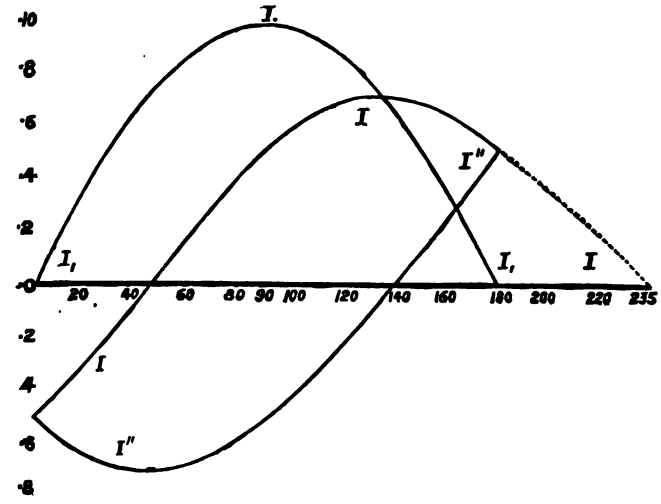

Fig. (1) $\frac{2\pi N}{T} = 1$; R=1; L=N.

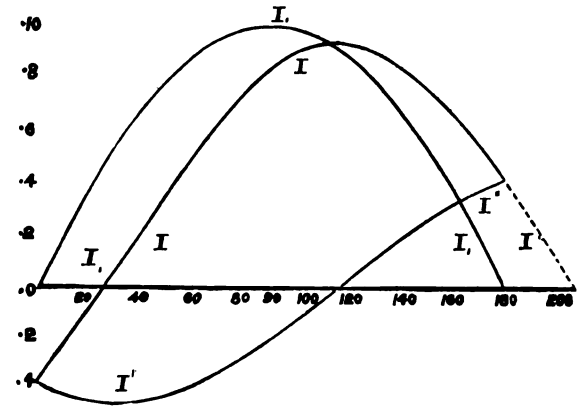

Fig. (2) $\frac{2\pi N}{T} = 1$; R=1; L=½N.

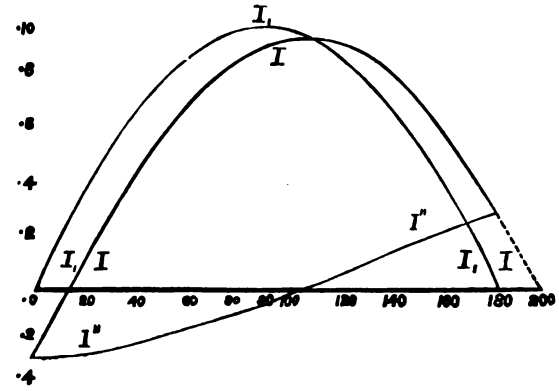

Fig. (3) $\frac{2\pi N}{T} = 1$; R=1; L=¼N.

We will next examine the three equations for the impressed, the self-induced, and the resultant currents by the aid of the curves to which they correspond. The equation for I″ has

Digitized by Google

just been given. For convenience of reference, we may repeat from the last paper the equations for I_1 and I:—

$$I_1 = \frac{2\pi N}{RT} \sin\theta$$

$$I = \frac{2\pi N}{T} \frac{\sin(\theta - \phi)}{\sqrt{R^2 + \left(\frac{2\pi L}{T}\right)^2}}$$

In the foregoing figures we have assumed that T has a constant value, and we have taken $\frac{2\pi N}{T}$ to be equal to unity upon the scale of ordinates. If we further make R equal to unity each curve will at the same time represent both electromotive force and current. This condition is assumed in figures (1), (2), and (3). The value of L alone differs in the three cases. In the first figure $\frac{2\pi L}{RT}$ (that is, a) is made equal to unity, and as we have already put $\frac{2\pi N}{T}$ equal to unity, this is equivalent to making L = N. In Fig. 2 we have taken $L = \frac{1}{2}N$, and in Fig. 3 $L = \frac{1}{4}N$.

From these curves the cause of the retardation of the resultant current is very obvious. The impressed E.M.F. and current has zero value when $\theta = 0$, but the resultant E.M.F. and current must become zero at that particular value of θ for which its two constituent terms are numerically equal, but with opposite signs; we have already seen that this condition is fulfilled at the angle whose tangent is equal to $\frac{2\pi L}{RT}$.

We may also notice the following points, each of which are implicitly contained in the formulæ, although they are much more readily observed from the figures.

(1) The curve of the resultant current cuts the axis upon the same ordinate as that upon which the induced current attains maximum values (both + and −).

(2) The resultant cuts the curve of the impressed current at the moment when it attains its maximum value; this is also the moment when the induced current has zero value.

(3) The fact that the impressed and the self-induced currents always "oppose" one another does not imply that they are at all times opposite in sign.

On the contrary, during a portion of each semi-revolution (or semi-alternation) these terms have the same sign. The period during which they are alike in sign is that during which θ has successive values from $\pi - \left(\frac{\pi}{2} + \phi\right)$ up to π. But the two currents still oppose one another during this period in the sense that while one is diminishing the other is increasing, and *vice versâ*.

(4) The statement that "the angle of retardation is constant" does not imply that the numerical values of the impressed and induced currents follow one another at the same intervals throughout the curves. In that case the curves could not cut one another. The meaning of the statement is limited to the consideration of *similar points* upon the two curves, such as the points of maxima and minima for instance. These will be found to follow one another at a constant interval.

In the next paper we will consider the effect of varying the resistance and the period.

ON PYROELECTRIC AND DOUBLY REFRACTING CRYSTALS, DIELECTRIC ACTION AND KERR'S PHENOMENON.

BY MISS J. M. CHAMBERS, B.SC.

We know that certain crystals, called pyroelectric (which are also doubly refracting and exhibit hemihedry), show electro-statical polarity when their temperature is altered. Thus, if they are heated one end becomes as if it were positively electrified, and the other end as if it were negatively electrified. If we pass a flame over the surface, this effect disappears as long as the crystal remains at the same temperature. But as the crystal cools electricity again appears at the same two ends as before, but the signs are now reversed. Sir W. Thomson has supposed these phenomena due to a polarity of the molecules in a certain direction, and that this polarity varies with the temperature. When the crystal is in contact with a conducting body, such as flame, electricity is attracted to the exterior of the body so as to mask the polarity.

Here the molecules appear to act as if they were charged with more electricity at one end than at the other (or, if we prefer, we may say that they have an excess of positive electricity at one end, and of negative at the other), and as if their charged ends were all turned one way. These bodies are crystallised, and crystallisation appears to exert a strong effect on the molecular arrangement. [It is probably the molecular arrangement which causes the ordinary rotation of the plane of polarisation of light in quartz. Of course it is well known that quartz is hemihedral, and that the rotation, whether right or left-handed, depends on the sign of the hemihedry. Quartz is pyroelectric. It is also said to possess a permanent diamagnetic polarity.]

When an electrophorus is rubbed with cat-skin we know that it becomes electrified. An actual positive charge is carried off with the cat skin, and the dielectric plate retains an actual negative charge. At the same time this negative charge will not pass off by merely touching the dielectric, as in the case of a conductor; in fact the only means of discharging the dielectric seems to be by heating it in a flame, and even this often does not do it completely, for, when the dielectric is again cool, a certain amount of charge reappears.

Now, suppose in some dielectrics the same polarity of the molecules exists as in pyroelectric crystals (this may be the case in some dielectrics without necessarily being so in all), but that, since the body is uncrystallised, the molecules are free to place themselves in any direction they please as long as no constraining force acts on them. As soon as the body is placed in a field of statical force the molecules will tend to place themselves so that their poles are joined by the lines of force. The reason that they will not, perhaps, all do this completely is that one molecule acts on another just as in magnetic bodies, and thus the action of the field is more or less interfered with. Thus, we have in the case of the dielectric just the same sort of thing as a magnetisable body, which, however, does not retain its magnetism when the magnetising force is removed, while in the case of the crystal we have a body permanently magnetised. The permanent polarity of the cyrstal is, however, masked by the electricity, which it gradually attracts to itself. In the case of a permanently magnetised body there is no similar manner of masking the magnetism present. This permanent polarisation here appears intimately connected with crystalline form.

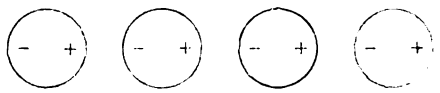
Now, as I said before, we charge an electrophorus by stroking it with cat-skin. Taking the above idea of polarised molecules we may suppose the following action to take place. We may suppose that during this stroking some action takes place between the dielectric and cat-skin, owing perhaps to a difference of potential between them, which tends to make the surface molecules of the dielectric place their axis all in the same direction, and their negative ends uppermost, and that the free positive electricity which would neutralise this polarity is carried off by the cat-skin while the negative remains internally, thus, on the whole, giving the body a negative charge as well as a polarity. The reason of the cat-skin carrying off the positive charge may be due to the heat generated by the friction which momentarily changes the state of polarity of the molecules, and the former state of polarity is restored when the temperature again sinks.

We know that a long thin needle of a dielectric will point along the lines of force in a strong field of statical force, just as a needle of a magnetic substance points along the lines of a field of magnetic force.

It is well knewn how uncertain is the sign of the charge of large masses of certain dielectric substances. They may appear to have externally a positive charge, and yet when placed in a metallic insulated vessel a negative charge may be indicated, and *vice versâ*.

Digitized by Google

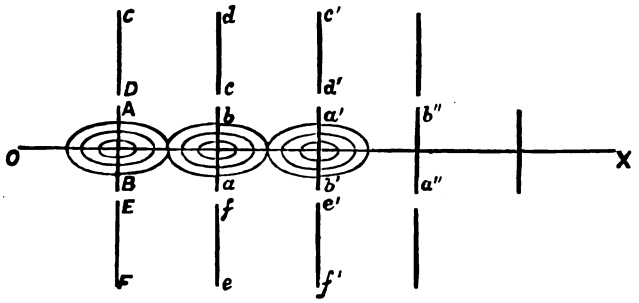
Perhaps in dielectrics with polarised molecules a certain amount of the energy expended in charging a condenser goes to turn the molecules just as a certain amount of energy is required to magnetise a magnet. And perhaps it is the gradual depolarisation of the dielectric that gives the residual charges in condensers. The energy used up in the polarisation is represented by the charge which is masked by it. Thus, suppose when a condenser is first discharged the molecules have all been turned in one direction by the electric force, as the figure shows, then there



will be a layer of positive electricity left on one end, and of negative on the other, to balance this polarisation. But the molecules being no longer subject to so great a constraining force as before will be now more inclined to place themselves in any direction, owing to the force exerted by one molecule on another. The electricity left at the surfaces of the dielectric will, in consequence of this depolarisation, become more or less free, and each removal of it will facilitate the turning of the molecules or the depolarisation of the body as a whole.

Of course it is not necessary that all dielectrics should have these polarised molecules. This polarity may vary in different bodies just as magnetic polarity varies. Dielectrics which give no residual charge may probably have unpolarised molecules.

In my "Simple Manner of Explaining Clerk Maxwell's Theory of Light" (*Phil. Mag.*, Feb., 1886, and *The Electrician*, Feb. 5), there is an action which may take place between the molecules which I have neglected to mention. Take a row of molecules above the first row. There will be a statical condensing



action between A and D and between B and E (on the same principle as in the new system of telegraphing with trains in motion). This condensing action should depend on K, the specific inductive capacity. Now, in my article I have treated the matter as if the whole transverse vibration took place in one molecule, while in point of fact, from the hypotheses on the size of molecules, it probably traverses several, and this condensing action is called into play as well as the one in accordance with Lenz's law. Thus we can see how K will affect the velocity of propagation.

In my articles on the "Rotation of the Plane of Polarisation of Light" (*The Electrician*, May 21st), and on "Hall's Phenomenon" (*The Electrician*, June 4th), I consider the action of magnetic and diamagnetic media on the two circularly polarised rays into which a plane-polarised ray can be resolved. I now propose to consider the action of the medium on the two rays plane-polarised at right angles to one another, into which a plane-polarised ray can be resolved.

Suppose we have an isotropic substance subjected to great pressure in one direction, the molecules will be brought closer together in that direction, and the condensing action will be increased in that direction; hence we can understand why pressure causes double refraction in glass, &c.

Again, in any substance in which there is a permanent polarity, as in pyroelectric crystals, probably this polarity has a fixed direction relatively to the shape of the molecule, and may be either along the longest or the shortest axis of the molecule, hence we may suppose that the molecules are closer together in one direction and farther apart in the other, in the same way as a solution with iron filings becomes clearer in one direction than in the other when acted upon by a magnetic force. It is not, however, necessary that the centres of the molecules should remain at the same distance apart in the two directions, as this supposes; for we may as readily suppose the velocity affected by the *number* of the condensing actions, that is the *number* of molecules traversed. In either case we can see why light should travel faster in one direction than in the other. Probably there is the same molecular arrangement in all doubly refracting crystals, but that when the molecules are not polarised they do not show pyroelectricity. Thus double refraction is accounted for in crystals.

Finally, in Kerr's phenomenon the molecules, when naturally polarised, place themselves along the lines of force with their plus and minus ends joined by those lines. As in the case of pyroelectric crystals, this polarity has probably a definite relation to the shape of the molecules, so that the condensing action is either greater or less along the lines of force than in the perpendicular direction, according as the substance appears to be expanded or contracted along these lines. Hence the double refraction. Even if the molecules are not polarised they would probably place their long axes along lines of force in this case, and there would still be double refraction. This is on the principle that a conductor points with its long axis along the lines of a statical field. Thus the charges which collect at the two ends produce a couple which tends to turn the conductor.

It is well known in the case of Kerr's phenomenon that the effect is far greater than what can be accounted for by the *pressure* exerted by the electric force. Not only is this the case,

but the double refraction takes place in liquids, in which, of course, the *mechanical* pressure must be equal in all directions.

On the other hand, strange to say, from the experiments of Duter, Righi, and others (*Journal de Physique*, *t.* VIII. p. 82, *Comptes Rendus*, *t.* LXXXVIII. p. 1,262), it appears that the actual compression is not so great as would be given by a mechanical pressure of the same amount, and, instead of being inversely as the square of the thickness of the dielectric as theory requires, it is inversely as the first power of the thickness. This also points to the fact that part of the energy is used up in the polarisation, also perhaps to the fact that the molecules are longer in the direction of the polarity than in the other.

THE PHELPS INDUCTION TELEGRAPH.*

The electrical section, acting as a sub-committee of the committee on science and the arts, to which was referred for examination the system of induction telegraphy invented by Mr. Lucius J. Phelps, of New York, presents the following report:—

A sub-committee of five members of the section visited New York September 28th, by invitation of the Phelps Induction Telegraph Company, and inspected the operations on a line worked by this system laid on the Harlem River branch of the New York, New Haven, and Hartford Railroad. The inventor, Mr. L. J. Phelps, and the secretary of the company, Mr. H. D. Hall, accompanied the committee. The branch has a double track from Harlem to New Rochelle, a distance of twelve miles, and the line is laid for this distance on the up-bound track. It consists of a No. 12 copper wire, insulated with okonite, laid in a groove cut in a 3in. by 3in. spruce strip, upon the top of which is tacked a ½in. strip, as shown in Fig. 1.

This wire is brought into the station at Harlem, where it is connected with a battery of 150 cells of a modified Bunsen

* Report of the Committee on Science and the Arts in the *Journal* of the Franklin Institute for July.

Digitized by Google

type, and to the ground. It is grounded at New Rochelle, but does not enter the office at that point. A combination car on each of three trains is equipped with the apparatus. An induction coil of ninety turns of No. 14 insulated copper wire passes through a 2in. iron tube, suspended under the car longitudinally between the trucks about seven or eight inches from the line wire. The upper portion of the coil passes through the car, and is hung along the side over the windows. The instruments are set up in the baggage apartment of the car. In a cabinet under the desk is a battery of twelve Bunsen cells.

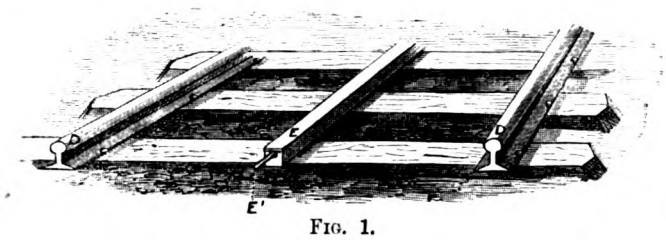


FIG. 1.

As the train left the station at Harlem the committee left messages with the operator at that point which were promptly sent to the parties on the train to whom they were addressed. Messages were also sent by the committee from the train to various parts of the country, which were received at Harlem, and forwarded by other lines. Three members of the committee, who were expert operators, did most of the work on the train. The messages were received on the car either by the Morse sounder or the telephone, in which could be read the Morse signals. The sender's key, however, instead of simply making and breaking the battery circuit, put in action, when depressed, a vibrator, or "buzzer," which sent alternate positive and negative currents to the line, producing a musical tone in the telephone so long as the key was held down. These rapid breaks were repeated in the induction coil circuit in which the telephone was placed, on the well known principle that whenever the circuit of a primary battery is broken or closed a current is set up in a parallel circuit at the instant of making or breaking. Without the buzzer it would be difficult to distinguish the dots and dashes in a telephone; with it, the letters can be read with even greater ease than by the ordinary Morse sounder. When the latter is used, a relay is introduced in the coil circuit with a delicately poised polarised armature which responds only to one pole of the battery, and therefore does not reproduce the rapid breaks heard in the telephone. Its movements, therefore, correspond with movements of the sender's key. It requires a more powerful current to work this relay than is required by the telephone. The battery carried on the car is not sufficient to operate the relay at the Harlem office, and all messages were received at that office by the telephone. This makes it necessary for the operator at that office to be constantly on the watch for business, as there is no means of calling his attention if the telephone is not at his ear. On the contrary, the operator in the car can switch in his Morse apparatus and can hear the call at a considerable distance when the train is moving.

After a stop of a few minutes at New Rochelle, the return trip to Harlem was commenced on the down-track, upon which there was no wire laid. The distance between the line laid on the up-track to the lower portion of the coil when on the down-track was 10ft. 11in., yet messages were received quite as well as when the coil was but eight inches from the line, although the tone in the telephone was much weaker, too weak to have any effect upon the relay of the Morse apparatus. It will be seen that the operator at Harlem could not receive messages sent from the train as readily as before, as the effect of the small battery on the car upon the line must have been quite weak; nevertheless, the messages were correctly received. It may be mentioned here that the upper portion of the coil was on the opposite side of the car from the up-track; had it been on the side nearest that track, it would have been nearly at the same distance from the line as the lower portion of the coil, and there would have been no sound in the telephone, as the currents induced in the opposite sides of the coil, being of equal strength, would have neutralised each other.

The test demonstrated the entire practicability of telegraphing between a terminal station and a moving train when but one line is used. If two lines were to be laid, it is evident that there would be an interference between the two in the induction coil on the car unless some means were devised for neutralising one of them. The system provides for this by so hanging the coils that the two sides will be as nearly equidistant from the circuit to be neutralised as possible. With two coils thus arranged, both circuits could be used simultaneously on the same car. Fig. 2 shows arrangement of coils.

The system, however, does not seem to provide for the neutralisation of the induction from one track line to the other line on the same track, which would be much stronger than the currents from the small battery on the car. For instance, it would be impracticable for the train despatcher to receive a message from a train while a message was being sent to that train or another train on the other line wire.

If several trains were upon the road at the same time, all would be in electric communication with the train despatcher by the same wire, but not with each other, because this would require a double induction, first from the car to the line and then from the line to the second car, and the battery carried on the car is far too weak to produce any results in the other car. If, therefore, the two trains should call the despatcher's office at the same time, the despatcher must say which one is first to use the line, as neither train would know that the other was calling.

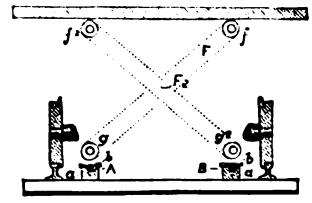

FIG. 2.

Your committee does not consider that its duty requires consideration of the many questions of railroad management which would arise if an opinion were to be expressed about the practical application of the system to existing railroad lines. The essential feature of the invention is the utilisation of induction to maintain communication between a moving train and the despatcher's office. That is successfully accomplished by ingeniously constructed mechanism worthy of high commendation. It is for the inventor and railroad managers to find practical use for the new system.

DEMONSTRATION OF THE ELECTRICAL RESIDUE.—Dr. Fr. Stenger, in Wiedemann's *Annalen*, according to the *Phil. Mag.*, says:—"If two strips of tinfoil are fastened at a suitable distance on a glass tube which has been evacuated as completely as possible, and are connected with the electrodes of an induction coil, continuous electrical currents are formed in the interior, and the gas becomes intensely luminous. If, then, the two tinfoil rings are insulated, the tube becomes luminous at frequent intervals, and often for several minutes together. This doubtless arises from the formation of a residue on the sides of the glass. The experiment was made in a far more striking manner as follows:—In a glass tube, about 2 centim. in the clear, closed at one end, a thin metal foil was introduced so that it covered about half the inner side. A wire soldered to this plate was hermetically sealed in the tube, and was provided on the outside with a small knob. Opposite the metal cylinder a strip of tinfoil was fastened. This small Leyden jar was then rarefied as completely as possible, and hermetically sealed. If this was charged from a small electrical machine for ten or fifteen minutes the residual electricities could be discharged, producing a bright illumination in the tube. This method of rendering visible very small quantities of electricity might possibly be used in repeating in another form the experiments of Roland and Nichols, on the formation of the residue in quartz and calc-spar.

IMPERIAL TELEGRAPHS.

Those whose hopes of Imperial Federation rest on the spontaneous growth of closer relations between her Colonies and the Mother Country, rather than on the artificial stimulus of political activity or personal enthusiasm, will find nothing to quarrel with in the proceedings of the Congress of the Chambers of Commerce of the British Empire, opened at the Indian and Colonial Exhibition last Tuesday week. Never before has such an opportunity been afforded for discussing the commercial interests of this great Empire in a truly Imperial spirit; and the event can hardly fail to be of service to all the countries concerned, though probably none of their representatives were so sanguine as to suppose that any bond more durable than that of mutual self-interest can be fashioned at present for holding the Empire together. Loyalty, patriotism, pride of race, are not the creations nor the creatures of discussion; they may be strengthened by a common danger in time of national peril, they may be fostered by friendly intercourse on occasions of national hospitality, but they cannot be formulated—much less forced—into a legislative mould; and our recent experience of constitution-making, even on a small scale, is not an encouraging precedent. The instinct of commerce, however, may do for us what the passion of nationality might shrink from attempting; and if anything will bring about a Federation of the Empire in the ordinary course of things we should be inclined to back Political Economy rather than political sentiment.

Among the foremost commercial considerations tending in the direction of Colonial and Imperial unity are the expansion and perfection of our Submarine Telegraph system. A short but interesting paper on this subject was read the first day of the Congress by Sir JAMES ANDERSON, and was reported at length in our columns last week. In the discussion which ensued, both at the Congress and in the Press, Sir JAMES ANDERSON appears to have created some alarm lest the Reforms suggested by him should involve an increased tariff—which in point of fact he greatly deprecated—and the abolition of code messages, which, however, he only threatened for those who were abusing the system. As regards increased rates, it is obviously not in the interest of the Cable Companies to diminish traffic; and, within certain limits, it is equally not their interest to forbid Code. But the Companies are quite justified in saying, if a privilege is abused to their serious inconvenience and pecuniary loss, that either the rates must be raised or the abuse removed. To neither of these remedies, however, did the paper recommend the Companies to resort. One of the means suggested for obtaining cheaper cabling was an inter-colonial subsidy or guarantee; and it would assuredly follow that no Government, whether English or Indian or Colonial, would allow itself to be fleeced by the unscrupulous employment of codes. The International Telegraph Conference legislates on this subject. If its members were owners as well as legislators they would enforce what they enact; but this is what in practice the Companies competing with each other are unable to do.

The unnaturally low rates which prevail on the Atlantic Cables put them out of discussion just at present, and Sir JAMES ANDERSON occupied himself chiefly with the cable system of the Eastern Hemisphere. To India and Australia the rates are exceedingly high, though, considering the distance, they are really much cheaper than those which are charged on inland telegraphs, which cost much less to erect. Small abatements make little difference in the traffic; and to grant a sensible reduction on a tariff of, say, 8s. or 10s. per word would inflict a heavy penalty on the proprietors of cables, who earn only a moderate dividend at the present rates. Experience has shown that the resulting increase of traffic will in a few years' time bring the revenue up to its old figure; but it has proved also that where this process has been compulsory by reason of competition the interval represents a serious loss, which is never made up by the business afterwards shared among the competitors. Cable owners are business men and not philanthropists, as Sir JAMES ANDERSON justly remarks; and the telegraphing public have no right to ask them to make a heavy sacrifice merely for the public benefit. He therefore submitted to the Congress two or three suggestions, by the adoption of which the public would be gainers and the Companies not losers. One method is for the State, or a number of States, to guarantee 4 per cent. dividend on the existing cables; another, which has actually been adopted by Germany in the case of one company, is to guarantee a certain amount per annum, but under conditions which will result, at the end of a given period, in the cable becoming the property of the German Government. A third plan is the one which is now being discussed with the Australian Colonies, whereby the average net earnings of the Companies during the past three years are assured them, the Colonies then reducing the tariff as low as they please.

These and other suggestions which have been under discussion all provide that the Companies shall not be gainers, the

Digitized by Google

Government aid coming only in the shape of a temporary guarantee, not as a permanent subsidy. They are not put forward in the names of the English Companies, or in their interests, but as friendly suggestions to our Colonial brethren, who, if they want a cheaper telegraphic tariff to Europe and India, are invited to accept some of the risk. There is a precedent for it in the mother country, where the State acquired the whole of the telegraphs in order to give the public a cheap tariff, which the private Companies could not afford to give. Events have shown, on the one hand, that the English Companies were right in not reducing their rates, and, on the other, that the State has not suffered—or did not until it took the new departure of last year—a permanent loss by assuming this responsibility. As to the alternative of a Pacific cable for the Australian service, we stated our views very emphatically as soon as the idea was broached. Sir JAMES ANDERSON has now argued the proposition so thoroughly that one may hope it is dismissed for ever. Cables follow trade, and so do the enemies' cruisers. Strategic cables can be laid when and where they are wanted. To lay long, deep sea, unremunerative cables is to invite certain loss in time of peace and immediate destruction in time of war.

Indirectly, no doubt, the Cable Companies might benefit by State responsibility and control of their tariffs which Sir JAMES ANDERSON'S suggestions would involve. The respective Governments would all be anxious to protect the property in which each of them was interested. At least this is theoretically probable; and of course the tendency would be to make for peace, just as trade and commerce make for it. Whether cable property would be respected in actual warfare is another matter. Probably it would if England were not in the fight. But as England owns perhaps eight-tenths of all the world's submarine cables, the probability of their being unmolested if she were at war with another maritime nation is very remote indeed. Continental nations are not likely, we fear, to sign away their natural advantages as we were so quixotic as to do by the Declaration of Paris. International understandings, however, have a value independently of their ostensible aim, and we should be glad to see any of Sir JAMES ANDERSON'S suggestions carried out among the leading maritime nations of Europe. In practice we can never get the Cables neutralised; but the next best thing is to lay them in such wise as to be easily protected if we have to fight for them, and quickly repaired if they are broken.

CORRESPONDENCE.

MAGNETIC RESEARCHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The last number of your journal, as well as the *Philosophical Magazine* for July, contains some interesting researches upon magnetism by Prof. G. Wiedemann, and I quite agree that they are fully explained by the movements of magnetic molecules, as first formulated in the theory of magnetism of De La Rive, and since extended by the innumerable researches of many independent observers, including myself.

The theory which I have advocated is based, not only upon my own experiments, which seemed to me to demonstrate clearly its truth, but upon the important researches of many others, including Prof. Wiedemann, and for which I have given them full credit.

I have proposed that this theory should be called the "Mechanical Theory of Magnetism," as granting that each molecule of iron or other magnetic metal is an independent and unalterable magnet. We can then reproduce all the known phenomena of magnetism by a mechanical change or arrangement of these magnetic molecules.

Prof. Wiedemann agrees with these views, but he now claims to be the first to have formulated this theory, dating his claim from papers published since 1857, although I have shown that it was first advanced by De La Rive in 1853.

The following is a quotation from my first paper upon the "Theory of Magnetism," Royal Society, April, 1883, relating to the theory which I advocated, and carefully pointing out its resemblance with that of De La Rive:—

"This theory has long been foreseen, and predicted in almost complete perfection as regards the rotation of the molecules, by many authors, the earliest of whose notices, and the most clearly defined as being very near the results obtained by myself, will be found in the remarkable work by De La Rive,* 1853, who in Chapter III., page 317, under the title of 'Influence of Molecular Actions upon Magnetism produced by Dynamic Electricity,' says: 'We have seen that heat, tension, and mechanical actions generally facilitate magnetisation. M. Matteucci has found that torsion and percussion, and mechanical actions, not only facilitate the magnetisation produced upon soft iron by a helix that is traversed by a powerful current, but they also contribute, when the current has ceased to pass, to the destroying the magnetism in a very rapid manner; the same philosopher has likewise observed that torsion, when it does not pass beyond certain limits, augments the magnetisation produced upon steel needles by discharges of the Leyden jar.

"'M. Marianini, who has made numerous and interesting researches upon magnetisation, arrived at curious results upon the aptitude that iron bars may acquire of becoming more easily magnetised in one direction than in another.'

"M. De La Rive sums up a series of interesting experiments in these remarkable words: 'The whole of the magneto-molecular phenomena that we have been studying lead us to believe that the magnetisation of a body is due to a particular arrangement of its molecules, originally endowed with magnetic virtue, but which in the natural state are so arranged that the magnetism of the body that they constitute is not apparent. Magnetism would therefore consist in disturbing this state of equilibrium, or in giving to the particles an arrangement that makes manifest the property with which they are endowed, and not in developing it in them. The coercitive force would be the resistance of the molecules to change their relative positions.'

"'There remains an important question to be resolved:—

"'Are mechanical or other actions, disturbers as they are of the electrical state, able of themselves to give rise to magnetism?'

"Du Moncel, in his remarkable work on magnetism, 1857, sustained and developed the views of De La Rive, and later, Wiedemann in Poggendorff's *Annalen*, 1857-1859, as well as in his remarkable 'Lehre von Galvanismus,' 1861, sustained a similar theory. Wiedemann has lately given a *resumé* of his researches in the *Lumière Electrique*, Paris, January 28, 1882, where he says—

"'Nous admettons que les metaux magnétiques sont composés de molécules qui sont une polarité magnétique; nous ne voulons rien préciser quant à la cause même de cette polarité, qu'elle provienne de la séparation des fluids magnétiques, des vibrations d'un milieu entourant les molécules ou mieux encore de l'existance de courant élémentaires.

"'Un corps ainsi constitué n'aura pas, en général, de magnétisme libre, parceque les axes magnétiques des molécules seront dirigés dans tous les sens et maintenus dans leurs positions respectives par les forces moléculaires. Mais une force magnétique extérieure, telle qu'une hélic où passe un courant leur donnera une direction générale.

"'En poursuivant cette hypothèse, M. Weber a réussi à expliquer théoriquement l'accroisement de la magnétisme d'une barre soumisse à l'influence d'une hélice aimantée jusqu'à un maximum.

"'Nous supposons, en outra, que les molécules dans leur mouvement éprouvement une certain résistance qui les empêche de suivre complètement l'influence des forces qui agissent sur elles.'

"In my preliminary note I gave the formulated results of a lengthened series of researches upon magnetism by the aid of the induction balance. As these agree in all important points with the theory of De la Rive, 1853, I do not wish it to be considered as a new theory or conception of molecular rotation, but as a theory based entirely upon researches into all the conditions of magnetism, and one which clearly defines the conditions of polarity and neutrality."

It is quite possible that the main points of this theory were published even before 1853, but in order to do justice I not only searched diligently through papers upon this subject, but wrote to my friend the late Comte Du Moncel (who had a remarkable knowledge of these earlier researches), asking him to point out the first to formulate this theory. His reply was, "undoubtedly, De La Rive."

It remains now for Prof. Wiedemann to show wherein his views differ from those of De La Rive, or cite some earlier date than 1857, for I cannot suppose he was not cognisant of the remarkable treatise of De La Rive published in 1853.—

Yours, &c.,
D. E. HUGHES.

NERVOUS FORCE AND ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, Mr. Arthur Willey, ought not to conclude that, because nobody has referred to his letter on this subject, therefore nobody has felt any interest in it. There is a kind of self-induction that checks an immediate response to letters public or private. However, it would perhaps be interesting if Mr. Willey would repeat his experiments in such a way as to eliminate the chances of chemical influence in his results about the right and left hand, as by holding platinum instead of copper. And was the deflection obtained a large one or a small one? We were told that the spot went *off the scale;* what would it indicate, according to the construction of the instrument?—Yours, &c.,

37, Burlington-road. E. ALDRED WILLIAMS.

INFORMATION WANTED.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have lately come into possession of a cylindrical electrical machine ("made and sold by Edward Nairne, Optician to Her Majesty, 20, Cornhill, opposite the Royal Exchange, London"), and I should be very much obliged if you or any correspondent will kindly let me know at what date (approximate) the above maker flourished, and in what repute his instruments were held. The machine I have is a splendidly made one. It is described as "Nairne's patent medical electrical machine (for ready money only). As many persons wish to try the effects of electricity, Mr. Nairne has contrived this machine, whereby any person, *without the assistance of another*, may try its effects in all the various methods practised by the most eminent medical electricians."

If you or your readers could furnish me with the required information I should feel much obliged.—Yours, &c.,

30, Edwyn-street, Leicester, July, 1886. T. H.

THE INCANDESCENT LAMP DISPUTE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We enclose copy of correspondence with the Edison and Swan United Electric Light Company with regard to a most extraordinary means which they are taking to find out who are using other than their lamps. We think that this deserves exposure, as their position is sufficiently strong without resort to this kind of fishing for culprits.—Yours, &c.,

Glasgow, 10th July, 1886. MUIR AND MAVOR.

Copy of correspondence with the Edison and Swan United Electric Light Company.

We have had sent to us, by Isaac Holden, Esq., M.P., in whose residence we fitted a number of your lamps, a letter from you under date 1st July, 1886, as follows:—

"We find that you are using electric incandescent lamps which are made in infringement of this company's patents, which have been recently upheld by the decree of the High Court of Justice, under proceedings instituted by the company against other infringers.

"I have to request that you will at once discontinue the use of these lamps, and upon your notifying me of your willingness to do this, I will make arrangements for sending for the lamps at such early date as may be convenient to you. If I hear from you not later than Thursday next, 8th inst., with the undertaking above referred to, the company will abstain from taking proceedings against you, either for an injunction or for damages—a course which the directors have authorised me to take—in the belief that you were not aware that by the use of the lamps in question you were infringing the company's rights."

We think this a most unwarrantable and vexatious proceeding on your part, calculated to have a very prejudicial effect on your interests and ours.

We are using your lamps exclusively, and think that you owe us an apology for this procedure.—Yours, &c.,

MUIR AND MAVOR.

Glasgow, 9th July, 1886.

ANOTHER ATLANTIC CABLE SUGGESTED.

Although at the present time there are in the Atlantic more than sufficient cables to do all the work required of them, as well as the probable increase of traffic for many years to come, a suggestion is being pushed by some French promoters to establish yet another system of submarine cables connecting Brazil with the United States and the various French colonies. For this purpose an attempt is being made to obtain a subsidy from the French Government. The question was discussed in the Chamber of Deputies, a full report of which we have had an opportunity of perusing in the *Journal Officiel* of the 12th inst. M. Bizarelli, on behalf of the Government, proposed a motion claiming urgency for the question, which immediately brought another deputy to his feet, in the person of M. Lucien de la Ferrière, who, in an exhaustive speech, opposed the motion on the grounds of an absence of urgency. He pointed out that what the Chamber was in reality asked to sanction was a subsidy of a million francs per annum for the next twenty-five years. What, of course, the promoters of the scheme urge on the Government is that the establishment of the new telegraphic route would be a more rapid and safer medium of communication between France, the Antilles, and French Guiana, and thus afford greater scope for the development of the French colonial trade. M. de la Ferrière had nothing to say against the motive which animated the Government in regard to the subject, which might, no doubt, be very praiseworthy, more especially in view of what they had now to disburse to the companies of other nations. Nor was he inclined to cavil at the principle of a proposal which might give an impetus to the manufacturing industries of France. What he protested against was the eagerness to grant urgency for the question, which might lead to precipitate action, the effects of which they might ultimately have very great reason to regret. The agreement which the Chamber was asked to ratify was with a company which had not even reached the embryo stage of its existence, and, he added, amidst the approving cheers of the Right, whose baptism had preceded its birth. He then proceeded to call the attention of the Chamber to two of the articles of the *projet de loi*, namely, the 1st and 12th. The first of these refers to the concession which it is said the Count d'Oksza has obtained from the Dominican Republic, by virtue of which the company would have the exclusive right to land cables upon its littoral, and connect them with the land lines already established. Before committing the country to such an undertaking M. de la Ferrière wanted to know a little more of the company promoting it; what was the guarantee for its completion which that organisation was prepared to offer; and what was the responsibility which it was proposed to take in regard to an enterprise from which, for all that he could see, it might reap the sole and exclusive advantage; what was to be the legal character of the prospective body; and under what judicial form was it to carry on its work; and what was the extent of its capital? These, and similar pointed questions, M. de la Ferrière desired to have satisfactorily answered before adopting the motion. He went even a little further, and maintained that according to the 12th article of the agreement the capital to be employed would practically be guaranteed by the State—nothing more nor less. Amid a good deal of interruption M. de la Ferrière proceeded to read the article in question to prove his contention. He was succeeded by M. Granet, Minister of Posts and Telegraphs, who urged as the principal reasons for supporting the motion the present unsatisfactory state of communication between France and her colonies. After a few further remarks from M. de la Ferrière, the Chamber came to the conclusion that urgency had not been established, there being 252 "ayes" and 258 "noes." Under these circumstances the first discussion of the question has been adjourned.

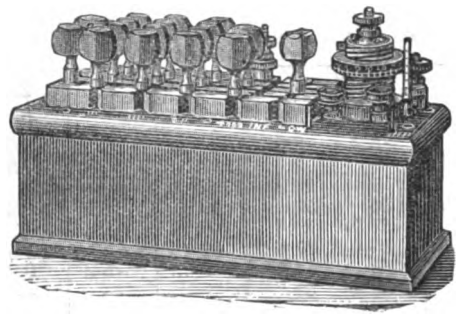
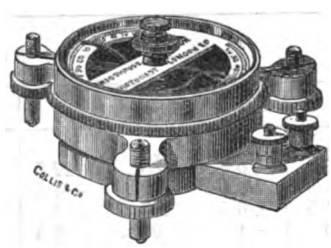
PORTABLE TESTING APPARATUS.

We have often remarked that it is necessary for the permanent success of electric lighting that the work should be tested as closely as telegraphic work is tested, and it is among the signs of the times that apparatus is being specially designed and constructed for this class of work. We herewith illustrate a portable combination bridge, manufactured by Messrs. Woodhouse and Rawson, which has been designed for them by Messrs. H. Davies and E. J. Moynihan. The great danger to be feared when careful testing is not carried out, and which is not yet properly recognised by electrical engineers erecting installations now considered perfectly satisfactory, is that a small fault unnoticed from a want of proper testing develops rapidly to an alarming extent, and that in some cases it soon causes a breakdown. To carry out a series of thorough tests



Woodhouse and Rawson's Portable Testing Apparatus.

it is necessary to have instruments for the measurement of very low resistances, such as the armature of a dynamo and the conductivity of cables and leads, as well as instruments for the measurement of high insulation resistances; and the expense and difficulty of carrying about the amount of delicate apparatus that has hitherto been necessary has no doubt been one of the causes why this most important matter of testing has been neglected. Messrs. Woodhouse and Rawson's combination bridge consists of two distinct bridges in one box, arranged so that the same connections are used with both, the only alteration in shifting from one bridge to the other being the shifting of the contact keys. The first bridge, which is separated from the second by the infinity plug hole, is a Wheatstone plug bridge capable of measuring resistances from 1 ohm to 10 megohms. This has coils of 100 ohms and 10 ohms in one



Woodhouse and Rawson's Portable Testing Apparatus.

ratio arm and 10 ohms and 10,000 ohms in the other, together with coils giving a total variable resistance of 10,000 ohms in the adjustable arm. The second bridge by which resistances may be measured from ·001 to 100 ohms without using a greater ratio than ten to one in either direction is a modification of a slide wire bridge in which the ratio wire is coiled in one groove and the battery lead in the other groove of a double threaded screw cut on an ivory cylinder. Contact is made between the two wires by a double brass spring attached to an ebonite ring, which screws up and down on the ivory cylinder, the ring being graduated from 0 to 100 on each half of its circumference, the number of half-turns being shown by a vertical graduated scale.

The whole length of the slide wire is thus divided into 1,000 parts. The unknown resistance is measured by adjusting the point of contact on the slide wire, which forms the ratio arms of the bridge, and so balancing the unknown against the most suitable of four coils, which respectively have resistances of ·01, ·1, 1, and 10 ohms. The infinity plug hole and the plug holes of these four coils are larger than those of the other part of the bridge, and have but one plug between them, the two bridges being separated by the infinity plug holes.

When the bridge is used for high resistances, the contact keys are turned to "high," and the infinity plug is put in. When it is used for low resistances, the contact keys are turned to "low," and one of the four above-mentioned coils plugged, leaving the infinity hole unplugged.

The use of the slide wire is advantageous for low resistances, and, combined with the other bridge, gives everything required for contractors' testing, and work of a similar character.

The bridge is usually fitted into a strong box, convenient for carrying it, which also contains a pair of large split terminals for connection to heavy cable, a primary or secondary battery, and a very delicate astatic galvanometer, with suspended needles, which is particularly neat and compact, and is provided with levelling screws.

It is sometimes preferred to fit the battery in a separate leather case, with straps for carrying, to prevent possibility of fumes injuring the bridge. The outside dimensions of the case carrying the bridge, spare terminals, galvanometer, and leads are only 13½in. by 5½in. by 7½in., the dimensions of the bridge are 9½in. by 4¼in., and it is undoubtedly the smallest made with so large a range.

MAGNETIC RESEARCHES.*

BY PROF. G. WIEDEMANN.

(*Continued from page 182*)

If the changes of magnetic moment which take place upon torsion enable a conclusion to be drawn as to the rotation of the molecules, it appeared of interest to investigate the processes connected with the changes still further; and first to examine a wire subjected to repeated twisting and untwisting within certain limits.

These experiments were made with the same apparatus, and by the same methods as previously described:—Wires in some cases (temporarily or permanently) logitudinally magnetised by currents led round them, in other cases (temporarily or permanently) transversely-circularly magnetised by currents led through them, were twisted and untwisted through a certain number of degrees, and their moments determined from the deflection of the suspended steel mirror. The deviations produced by the magnetising current were compensated as before. By repeatedly raising and lowering the compensating ring, its constancy during the experiments on temporary magnetism could be controlled.

In the following tables, in order to economise space, the data are given only for the 1st, 2nd, 3rd, and nth torsion and detorsion after twisting the wire to and fro so many times that upon repetition of the experiments the same results were obtained. t denotes the angle of torsion, m_t the temporary, and m_p the permanent magnetic moment.

The magnetism of the nickel wire had diminished so much after repeated torsion that measurements with it could not be made use of.

The results of these observations for the last torsion and detorsion, after attaining a permanent condition, are represented in Figs. 2 to 9 by curves whose abscissa represent torsions and ordinates the corresponding magnetic moments. The curves marked I., II., III. represent the results obtained with the first, second, and third torsion and detorsion of the soft-iron bar.

The curves show that after the wires have been accommodated by repeated deformation, the curves representing the magnetism are nearly symmetrical for rising and falling torsion,

Digitized by Google

beginning from the minimal and maximal torsions of 0° and 210°. With the temporarily longitudinally magnetic iron wires—the moments are nearly equal for the later torsions—they rise similarly in consequence of torsion and detorsion, and then fall again to the limiting-point. The curves, however, rise more rapidly than they fall, so that the maximum of the temporary movements is obtained before the half-torsion or detorsion.

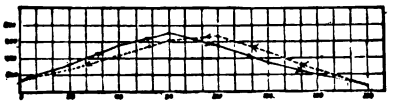

FIG. 2.—Soft iron temporarily magnetised longitudinally.

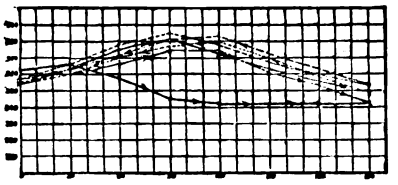

FIG. 3.—Iron wire repeatedly longitudinally magnetised temporarily.

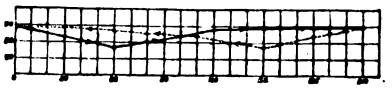

FIG. 4.—Nickel temporarily magnetised longitudinally.

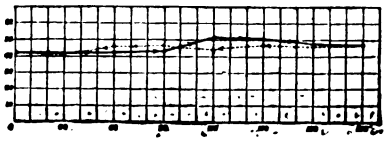

FIG. 5.—Soft iron permanently magnetised longitudinally.

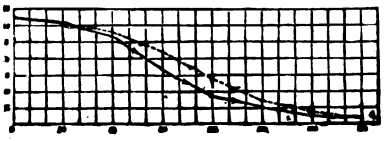

FIG. 6.—Nickel permanently magnetised longitudinally.

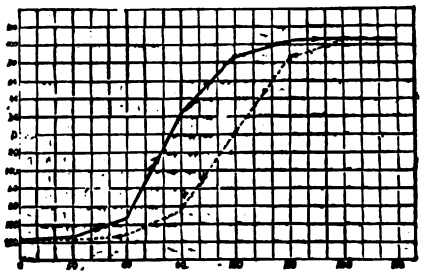

FIG. 7.—Iron temporarily magnetised transversely.

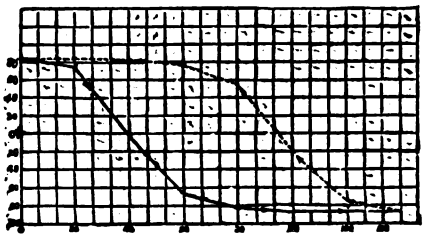

FIG. 8.—Nickel temporarily magnetised transversely.

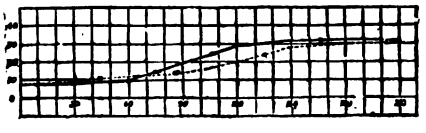

FIG. 9.—Iron permanently magnetised transversely.

With the iron wires permanently magnetised longitudinally and temporarily magnetised traversely, the behaviour is similar, only the moments at the two limiting points of 0° and 210° are different. Starting, however, from these points, the curves run similarly. The moments again change more rapidly at the beginning of torsion or detorsion than at the end. With nickel the moments change in the opposite direction; but in other respects according to the same rules as with iron.

We may hence conclude that, within certain limits, the molecules, in consequence of repeated twisting to and fro, become movable; so that they perform nearly equal motions for equal torsions from the two limiting values. With temporary longitudinal magnetisation the tendency of the magnetising force is to place the molecules with their magnetic axes longitudinal, in consequence of which a final condition is attained in which they deviate at the limiting points equally from their most nearly longitudinal position. *A priori*, we should expect that they would be most nearly longitudinal in the mean position, *i.e.*, at half torsion and detorsion; and there the wire would show its maximum of longitudinal magnetism. The deviation from this result shows that at the commencement of torsion or detorsion the molecules are more quickly influenced by the acting forces.

(To be continued.)

ELECTRICAL THEORIES.

BY PROF. J. J. THOMSON, M.A., F.R.S.

(Continued from page 181.)

Let us now go on to consider the force acting on the medium conveying the current.

If we consider a continuous distribution of currents, the kinetic energy

$$= \tfrac{1}{2}\iiint (Fu + Gv + Hw)\, dx\, dy\, dz.$$

If we derive the force parallel to x by the variation of the energy in the usual way we find, just as in Helmholtz's paper*, that the force parallel to x

$$= \left\{ v\left(\frac{dG}{dx} - \frac{dU}{dy}\right) + w\left(\frac{dH}{dx} - \frac{dU}{dz}\right) - F\left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}\right) \right\}$$

or with our notation

$$= v\left\{\frac{dG}{dx} - \frac{dU}{dy}\right\} + w\left\{\frac{dH}{dx} - \frac{dU}{dz}\right\} - FP,$$

and that on any surface where there is a discontinuity in the values of u, v, w there is a force equal per unit of area to

$$F\{l(u_1 - u_2) + m(v_1 - v_2) + n(w_1 - w_2)\}$$

or $F\Sigma$.

In the same paper it is shown that it follows from the principle of the conservation of energy that the force exerted by a distribution of currents equals the force given by Ampère's expression along with a force at the point $\xi\eta\zeta$ whose component parallel to the axis of x equals

$$\iiint \left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}\right) \frac{x-\xi}{r^4} \Big(u'(x-\xi) + v'(y-\eta) + w'(z-\zeta)\Big)$$
$$dx\, dy\, dz + \iint \left\{ l(u_1 - u_2) + m(v_1 - v_2) + n(w_1 - w_2) \right\} \frac{x-\xi}{r^2}$$
$$\Big(u'(x-\xi) + v'(y-\eta) + w'(z-\zeta)\Big) dS;$$

or with our notation

$$\iiint P \frac{x-\xi}{r^4} \Big(u'(x-\xi) + v'(y-\eta) + w'(z-\zeta)\Big) dx\, dy\, dz$$
$$+ \iint \Sigma \frac{x-\xi}{r^4} \Big(u'(x-\xi) + v'(y-\eta) + w'(z-\zeta)\Big) dS,$$

where u', v', w' are the components of the current at the point $\xi\eta\zeta$; so that in addition to Ampère's forces we have additional forces wherever P and Σ have finite values. From the above

* *Die elektrodynamischen Kräfte in bewegten Leitern*, Crelle, LXXVIII p. 298, 1874, or *Gesammelte Werke*, Vol. I., p. 753.

Digitized by Google

expressions we see that any element where P has a finite value exerts a repulsive force equal per unit of volume to

$$\frac{P}{r} i \cos\theta,$$

tending from the element; where r is the distance of the element from the point at which the force is reckoned, i the intensity of the current at this point, and θ the angle between the direction of the current and r. Any element of surface where Σ has a finite value exerts a repulsive force equal per unit of surface to

$$\frac{\Sigma}{r} i \cos\theta,$$

where the notation is the same as before. Of course none of these forces exist in Maxwell's theory. They could be most easily detected in cases where the part of the forces given by Ampère's theory vanishes as it would for the case of an endless solenoid. In this case, though the Ampèrian forces vanish, the forces due to the discontinuity in the current do not, so that if the endless solenoid were to move under the action of external currents it would denote the existence of discontinuity in the current. An experiment of this kind has been made by Schiller; we shall discuss the results of it later.

To sum up, the differences between the most general theory which takes into account the action of the dielectric, and Maxwell's, are—

1. The existence of a normal wave in the general theory, but not in Maxwell's.
2. The difference in the velocity of propagation of the transverse wave.
3. The difference in the relation between electric currents and magnetic force.
4. The forces which arise from discontinuity in the currents.

The Experimental Evidence as to the Truth of the Various Theories.

The theories we have considered may be divided into two great classes, according as they do or do not take into account the action of the dielectric surrounding the various conductors in the field. The first thing, therefore, that we have to do is to see whether experiment throws any light on this point.

When a dielectric is an electric field it experiences a change in its structure; this is rendered evident by the alterations in its volume and elasticity observed by Quincke, by the change in its optical properties observed by Kerr, and also by the fracture of the dielectric when the field is made sufficiently intense. So that whenever an electromotive force acts on a dielectric it produces a change in its structure which we shall always speak of as polarisation. This, strictly speaking, has only been directly proved for electromotive forces produced by charges of statical electricity; but, unless we are prepared to say that the electromotive force due to statical electricity is in some way different from that due to a changing current, we must admit that when an electromotive force of the latter kind acts on a dielectric it polarises it. And we are not without experimental evidence that the electromotive force due to variations in the vector potential does produce some of the effects of the electromotive force due to a charge of statical electricity. Rowland's experiments have shown that a moving electrified body will set a magnet placed near to it in motion. It follows from this, by dynamical principles, that if we have the charged body initially at rest and move the magnet it will, if no other forces act upon it, be set in motion; so that in this case there is an electromotive force due to the motion of the magnet, *i.e.*, the variation in the vector potential produces the same effect on the electrified body as the electromotive force due to a charge of statical electricity. For this reason we shall suppose that the electromotive force due to the variation in the vector potential always produces effects on a dielectric on which it acts of the same type as those which have been observed to arise from the action of an electromotive force due to a charge of statical electricity. Let us now consider a magnet surrounded by a dielectric. If we set the magnet in motion, we produce an electromotive force which polarises the dielectric. Let us, to fix our ideas, consider an element of the dielectric and the magnet. When the magnet moves it polarises the dielectric; it follows from dynamical principles (an extension of the principle of action and reaction),* that if the polarisation of the dielectric be altered the magnet will move, so that a change in the polarisation of a dielectric produces a magnetic force.

Again, let us instead of the magnet consider a coil of wire conveying a current. A change in the rate of flow of the current produces a change in the polarisation of the dielectric; it follows that a change in the rate of change of the polarisation of the dielectric will produce a change in the current, *i.e.*, will produce an electromotive force.

It follows too, from dynamical principles, that as the change in the polarisation of an element of the dielectric due to the change in the current depends on the distance of the element from the current, there must be a force between the current and the element when the polarisation of the latter is changing. Thus we see that a change in the polarisation of the dielectric must produce all the effects of an ordinary conduction current, so that it is only absolutely necessary to consider how the experimental evidence affects those theories which take the action of the dielectric into account. As, however, the experiments which have been made are few in number, and are all concerned with interesting points, we shall consider them in their relation to all the theories, and not only to those which take the dielectric into account.

Schiller's Experiments.

The first experiment which we shall discuss is one made by Schiller, and described by him in Poggendorf's *Annalen*, Vol. CLIX., pp. 456, 537; it was intended to test the potential theries of Neumann and Helmholtz. We saw that, according to these theories, in an unclosed circuit there are, in addition to the forces due to the elements of current, and which are expressed by Ampère's law, forces arising from the discontinuity of the currents at the end of the circuit. If we have an end of a circuit where the current stops, and the electricity accumulates at the rate de/dt, it will exert on an element of current of length ds traversed by a current of intensity i a force tending to the end and equal to

$$A^2 ids \frac{de}{dt} \frac{\cos\theta}{r}$$

where θ is the angle between the element of current and the radius drawn to it from the end. If we calculate from this expression the couple produced by an end on an endless solenoid, or on what is practically the same thing, a ring magnet, we shall find that the couple tending to turn the ring about an axis in its own place will not vanish, whilst the couple arising from the forces given by Ampère's law will. Thus, if the ring rotates, as it should according to the potential theory, it must be from the action of the end.

In Schiller's experiment the end of the current was the end of wire connected with a Holtz machine. This was placed near to a ring magnet which was suspended by a long cocoon fibre; the magnet was protected from electrostatic influences by being enclosed in a metal box connected with the earth. Schiller determined the intensity of magnetisation of the ring magnet and the quantity of electricity passing through the point, and he calculated that if the potential theory were true, he ought to get a deflection of the magnet of about 27 scale divisions, instead of which there was no perceptible deflection.

This experiment shows conclusively that the potential theory is wrong if we neglect altogether the action of the dielectric, and assume the current to stop at the end of the wire. If, however, we take the dielectric into account, the experiment tells us nothing as to whether Maxwell's theory or the more general one is true; for since the current from the Holtz machine is steady, as much electricity flows out from the end of the wires as arrives there; and thus there is really no discontinuity in the current, the only difference being that before reaching the end the current is flowing through copper and after passing it through air. The condition of things at the end of the wire remains steady, and thus the quantities which we denoted by P and Σ vanish.

The experiment might, however, be modified so as to be capable of distinguishing between the theories which take the

* See a paper by the author of this report "On some Applications of Dynamical Principles to Physical Phenomena," *Phil. Trans.*, 1885.

Digitized by Google

dielectric into account. For suppose that, instead of letting the electricity escape through the point, we never let the potential at the end of the wire get so high as to allow the electricity to escape; then, if the wire is initially uncharged, the condition at the end will be changing whilst the wire is charging up, and thus Σ will have a finite value; so that if the magnet were sufficiently delicate and remained undeflected, whilst the point was surrounded by dielectrics of all kinds, it would show that Maxwell's theory is correct.

I have calculated the effect which would be produced on Schiller's suspended magnet, and find that it is too small to be observed; as, however, the time of charging up the wire will be very small compared with the time of vibration of the magnet, the effect will be of the nature of an impulse, so that in this case there will be considerable advantage in having the moment of inertia of the suspended magnet small; while, as Schiller arranged the experiment, there was no such advantage, as the thing expected was a steady deflection. Thus, if the ring magnet were retained it would be desirable to make the opening of it as small as possible, retaining the same cross action. I think the arrangement could be made sensitive enough to be deflected if the value of Σ were any considerable fraction of the rate of increase of the electricity at the end of the wire.

(To be continued.)

PROF. FORBES' CANTOR LECTURES.

LECTURE VI.—(Conclusion.)

At the conclusion of my last lecture I stated that I proposed to make an alteration in the programme. I had originally intended that my concluding lecture should have been on the subject of electrical measurement, showing how a system of units has been evolved, each one depending upon the other. This is a most important subject, and I should have been glad that it should have been included in this course of lectures. But the course of lectures was started with a special object in view—that was, of going into all those fundamental principles and laws of electricity which regulate those numerous applications of it which we meet with every day; in other words, to enable those who are not professional electricians to understand what they meet with in the course of their daily lives in the applications of electricity. For this reason, as I announced last week, I intend to change the subject of this, my last lecture, and to review in a sketchy manner some of the most important practical applications of those general laws or principles and discoveries which we have been considering during the previous five lectures. To-day I shall be dealing with the more important of those applications. Amongst those applications I think you will all agree with me that the most important at the present time is the great facility which we have acquired for collecting and converting into power almost unlimited quantities of electricity. This is the result of the invention of dynamo machines. After I have dealt with this subject I propose to say some words about another application which has had a great deal to do with the development of civilisation, and that is the invention of the electric telegraph. In conclusion, I propose to speak of a still later invention, but one which has attained a vast application in the short period of its existence, namely, the telephone. In the development of invention applied to the progress of civilisation there are two essentially different parts to be carried out. There is the grand field of discovery, and in this field of discovery in electrical science no name stands higher than that of our celebrated countryman, Faraday, which has been so often mentioned in these lectures. Secondly, there is the work of the practical inventor who utilises the tools which have been put into his hand by the discoverer, and who applies those tools to evolve practical ideas and turn out inventions which assist the progress of civilisation. Now, I am first going to speak to you about the manner of constructing a dynamo machine, and all I can hope in this sketchy review is to be able to tell you enough about it, so that when you see a dynamo machine running you will be able to appreciate the object of the several parts of that machine, and you will be able to judge to some extent how far those different parts seem to be suitable to fulfil their offices. In my last lecture I showed you the action of this little machine, which was due to Faraday, consisting of a coil of wire, which is capable of rotation round one of these diameters. In doing so it cuts the earth's lines of force—that is to say, it cuts the direction in which the earth's magnetic force is exerted, and whilst it is cutting that direction it is creating a current of electricity in the coil of wire. This is the fundamental notion in the construction of all dynamo machines such as we have at present. Moreover, in this little instrument which I showed you it is necessary to introduce what is called a commutator, to reverse the current at each half revolution of the coil, because, as the coil takes successive half turns, the direction of the current in that coil is reversed, and therefore we must have a commutator to reverse the current going to the external circuit in order to keep the current continually in the same direction in that part of the circuit in which we wish to make use of it. In order to illustrate the principle of the dynamo let me first show you a small apparatus which has been called the electric hammer. It is rather an ingenious apparatus, and I will try to describe it in a few words to you. I have here a vertical tube, with a coil of wire from the bottom to the top. At every five turns there is a separate wire led on to one of these pieces of brass. I think there are fifty of them in all, if I remember rightly. The first five turns are connected with the piece of brass nearest to me, the next five turns with the second piece, and the next five turns with the third piece, and so on. I introduce into this tube a piece of iron; and I have the means of causing any set of these turns of wire round the vertical column to have a current passing in them. The wires from my battery come to these two pieces of wood, and one of them is connected to a strip of metal which just covers ten of these brass pieces on the flat board, so that by moving this hand-piece along the flat board, and making contact with the different pieces of brass, I can send the electric current through any ten of these sets of turns from the bottom of the vertical column right up to the top of it. Thus, if I introduce a piece of iron into the tube which forms the vertical column, then, by making contact and sending the current through this wire, I can suck the iron right up to the top and down again with very considerable force. I will put a piece of paper on the top of the tube in order that you may see the rising of the iron, which will cause the paper to move. [Experiment.] And now you will see the force with which I am able to bring it down. [Experiment.] It creates a very considerable blow. This is a sort of model of an arrangement called the electric hammer. Well now, I was able to show you by means of the galvanometer the direction of a continuous current. The whole principle of the dynamo machine is contained in this apparatus. The modifications which we find in special dynamo machines are merely modifications to increase the power which we derive from the action which is exhibited by this little instrument. If I were to introduce a pole of iron into the centre of a coil which is rotary, the earth's magnetism would induce a considerable amount of magnetism in the iron while the thing was rotating. Much greater intensity of magnetisation would therefore be got by the coil in the course of its rotation with the iron than actually takes place where there is no iron. That is one of the steps which have been taken in the devolution of the dynamo from this simple apparatus. Then again, the earth's magnetism is comparatively feeble. We are able by means of electro-magnets to produce far more powerful fields of magnetisation than that which is produced by the earth. And the second step in the evolution of the dynamo is to produce a more powerful field than the earth's magnetism—in fact, to produce as powerful a field as we can possibly succeed in doing. That is done by causing the rotating part to travel between the poles of a powerful magnet—similar to these. [Shown.] The principal variations which we find in the construction of dynamos depend to a larger extent upon the proportioning of these electro-magnets so as to produce the most intense field possible for the revolving part to travel through. The revolving part is usually called the armature, and the iron part with its coils round it, which produces the magnetic field, is usually called the field-magnet. I will now show you upon the screen in succession a few slides illustrating the progress of the dynamo machine, from this simple apparatus which you have already seen at work, up to the latest types which you can all see at the Indian and Colonial Exhibition and numerous other places. I will begin by showing you the apparatus which was first used by Faraday in order to produce an electric current. Having projected the image on the screen, he continued: This was one of the first ideas of the dynamo. As a dynamo it is not good. I will tell you why, and in pointing out why it is not good you will appreciate the various stages of progress in other machines. There is an electromotive force tending from the centre of this disc, and there is a tendency to complete the circuit either through the external wire or through the mass of metal on the copper disc. The resistance of the copper disc is far less than the resistance of the wires in the external circuit, and consequently the electromotive force which is created in the interior tends to create a circulating current in the disc rather than currents through the external circuit, which are therefore comparatively feeble. The next apparatus which I will show you is one of the first practical means of producing electricity, that invented by Pixii. [Shown.] Here we have an axis with a horseshoe magnet supported upon it, the poles being in the same horizontal plane. Its pole pieces are two coils of wire, with the iron here. [Indicated.] As it rotates it alternately magnetises one of these bobbins with this pole north and the last pole south. The position of these poles is continually inverted as the magnet rotates. You will notice that the current comes down to a commutator which rotates with the magnet, and by means of split tubes fixed upon the axis the direction is reversed at each half revolution exactly as it was in the apparatus of a more experimental kind which Faraday introduced. The next apparatus is very similar in character. This is a Clarke machine, which contains the same parts, although they are somewhat differently arranged. [Shown.] Here you will notice that the horseshoe magnet is fixed in position, and that the two coils of wire are fixed upon a horizontal axis, and revolve upon it. The ends of the wires of these bobbins come to the two opposite parts of the straight tube on the horizontal axis, and springs at the opposite sides of the axis touch the plate at the top, and so by means of that arrangement the current is led away from the springs to the external circuit. The next machine is one devised by Halske for the purpose of intensifying the action, of which I have been speaking, very considerably by using a more conveniently arranged system of field magnets and armature. The armature is not shown in this, because in order to give the maximum amount of magnetism in it the revolving armature must be almost completely surrounded by the pole pieces of the field-magnet. These two parts here [indicated] are connected with the two ends of the wire upon the armature, which is inside, and it tends to reverse the direction of the current in the other circuit exactly in the same way as the other apparatus which I have been showing you. I will show you this commutator on a large scale in order to contrast it with the arrangement which has been produced at a later date, and which is now almost universally adopted for the commutator of a dynamo machine. [Shown.] Some

Digitized by Google

dozen years ago Mr. Gramme invented a machine founded upon these great principles that we have been studying, but introducing some important modifications, and the plan he adopted was, instead of taking a single coil of wire surrounding a piece of iron to get the magnetic field, he took a metal ring and wound a wire round it, threading the wire through the ring at every turn. [Shown.] I will now put in the Gramme commutator, and you will be able to see how the connections were made. [Shown.] I will now project on the screen one of the machines of date before Gramme's, but which is of the utmost importance in the subsequent history of the development of dynamo machines. Here you see in Wilde's machine—at the top of the apparatus—a horseshoe magnet with its armature, exactly like Siemens'. Below that we have a much larger machine of the same character, with one difference. The difference is that instead of having a horseshoe magnet we have one of those powerful electro-magnets surrounded with coils of wire. The electricity developed in the first machine is utilised separately and entirely in magnetising the field-magnets of the large machine below. The consequence is that from this little machine we are able to produce an intense magnetic field, and magnetise very powerfully the revolving armature of the lower machine. In this way Henry Wilde showed us how a very feeble quantity of magnetism might be indefinitely increased, for obviously we might employ the second machine to excite the field-magnets of a third, and so on indefinitely. That, I think, has been one of the most important steps in the progress of the evolution of the dynamo. I will now show you a slide representing a machine of great historical interest, though it was never of great importance as a practical machine. This was invented by Pacinotti before Gramme. It is very much of the same type, and you might call it a sort of laboratory experimental Gramme machine before Gramme had applied the principle to industrial applications, and originally worked simply as a motor. This was not intended originally to generate a current of electricity. It was intended to do mechanical power by sending a current of electricity through it. That is one of the most beautiful effects in connection with dynamo machines. It has been found that a machine which produces electricity in an economical manner is at the same time capable of being driven as a motor in an efficient and economical manner. We can either convert mechanical power into electricity by this machine, or we can convert electricity into mechanical power. I will now show you the Gramme ring in the process of its formation. The ring itself is generally made from wire to prevent induced currents being created, as would undoubtedly happen if it were made of solid iron. The section of the battery is shown in this drawing, likewise a series of coils which have been slipped over it. This is the way in which the rings were first made, but as a matter of fact they are not so made now. The ring now is made in contact, and then these coils are wound upon the ring. The two ends of any of these coils are attached to two bars of the commutator, which we have already seen on the screen. Numerous improvements have been made in the construction of the Gramme machine, but this was really the type of armature which first brought about the dynamo machines which are applicable to industrial purposes. I will now show you the field-magnets of the Gramme machine. [Shown.] There are two electro-magnets with pole pieces in the centre of the coils of wire wound round these electro-magnets so as to magnetise the pole pieces in opposite directions, the one being north and the other south. The magnetic circuit is completed by the two iron standards. I have a model upon the table of a comparatively small Gramme machine, and you will see the iron parts as they are before any wire has been wound upon them at all. [Shown.] I will now project on the screen the complete Gramme machine as it was first created on a large scale for the purpose of electric lighting. I will draw your attention to the different parts of it, so that when you are looking at a dynamo machine you will be able to appreciate every part of it. The electro-magnets are at the top and bottom. The pole pieces are masses of iron, and you will notice in the centre of the conductor the ring, which is revolving upon a horizontal axis. The wires from the different coils in the ring are brought down to the commutator, which is a cylinder built up of separately insulated brass bars upon a horizontal axis. Brushes composed of flat strips of wire bear upon these bars of the commutator as it rotates so as to collect the electricity. These are the essential features of the dynamo machine, and when you are looking at any particular dynamo machine you will always be able to see for yourselves which are the field-magnets, which are the pole pieces of the field-magnet, which is the revolving armature, which is the commutator, and which are the brushes, and by studying the differences in these pieces you will be able to appreciate the advantages there are in the different kinds of machines. Here, again, is a Siemens machine, made much on the same principle. Here are the coils of wire about the field-magnets. The pole pieces are placed upon either side of the armature. The armature itself is only visible at its end, revolving about its horizontal axis. The armature in this case does not consist of a ring but of a solid cylinder of iron. The coils of wire go right round the cylinder, and they are connected at the terminals with bars of the commutator in exactly the same way as you saw before, and the current is carried off with the brushes, which press against the bars of the commutator. Next we have a machine totally different in character to the Gramme machine. But here again we see the field-magnets, pole pieces, armature, commutators, and the brushes in the same way, and we are able to identify the functions of each. This is the Brush machine; but I need not go into the details of this machine. The pole pieces are visible, facing each other. The revolving part consists of a ring partly visible to you, and the coils of wire are partly visible to you. The wires pass along this way to the commutator, which is somewhat different in form, but which performs the same functions, and the current is carried away by the brushes in exactly the same fashion as the other machines. I will now show you the machine which was used for lighthouses in days of old. This is the machine of which Faraday said when it was shown to him as the product of his discoveries, "I gave you a baby and you show me a giant." [Shown.] Here is a Siemens alternate current machine driven by a direct current dynamo. This consists of a series of electro-magnets with the poles facing each other, and coils of wire on a wheel revolving between these iron pole pieces. The alternating currents so generated do not require a commutator, but only a collector, which is fixed upon the axis, and consists of two rings which are connected one with one end of the wire, and the other with the other end of the wire, and then the brushes carry off the current which is utilised in the electric light. This is another machine constructed by Edison in 1881. These horizontal bars are electro-magnets. The pole pieces, as you see, are enormous masses at the ends of these bars. The armature is of much greater diameter than that of any we have been examining, but it is constructed on the same principle, being of a solid mass of iron very much like the Siemens machine. Lastly, as I happen to have a drawing of it I will show you the Gordon machine, which is made on the most excellent economic principles. This is one of the most successful from the thoroughly workmanlike way in which it has been made. I have several other things which I wished to show you, but I have taken up longer time in the description of the machines than I had intended. I will now let you see how these machines are applicable for the purpose of converting electricity into a motive power as well as motive power into electricity. I have here a collection of models of different machines—a large number of them—which it will be very interesting to some of you to look at afterwards. I have the Siemens, Pacinotti, Brush, and the Gramme; and I have also some other models of the same type. [Severally indicated.] As to the application of those powerful currents which we were able to develop by means of the dynamo I need say very little. We have brilliant evidence of it before us just now in the glow lamps which are lighting up this room. But I will throw upon the screen an image of the carbon points which are used in the arc lamps, and I wish to draw your attention to one point, and that is the crater in the positive pole.

A positive pole in consequence of that action wears away more rapidly than a negative. You will see that that crater is a most intense source of light, and by directing the crater in a particular direction we are able to illuminate with great intensity any place. In lighthouses, however, they do not use continuous current machines, and consequently there is no crater, and in appearance the two poles, the ends of the carbon, are identical in lamps lit by an alternating current machine. I might draw attention to other appliances which are very useful applications of electricity, such as secondary batteries or accumulators, which are a very perfect form of battery. By sending a current in the opposite direction to that in which they naturally create one, we are able to recover the elements of the substances in the battery, and to reconstitute them so that by means of a dynamo machine we are able to renew the battery as often as we please. I might draw your attention to the brilliant application of induced currents shown by this apparatus—a secondary generator or transformer. We have simply an electro-magnet with two coils of wire round the iron core. An alternate current of electricity is sent through one of these coils, and the second coil is connected with the lamps which are to be lighted. By this means we are able to convert a current of high tension into a current of low tension. The apparatus is one which is bound to be a most important feature in the application of electricity of the lighting of towns. Especially when we go to a great distance there is a great economy effected in being able to use high tension currents—currents with high potential to carry them over a distance. In houses we must have currents with comparatively low E.M.F., and the power that we have of transforming high potential into low potential currents will help us with the distribution of electricity largely in the future. But time is slipping away. I must leave this subject, and go to the second application which has affected the world so much, viz., the application of electricity to telegraphy.

There I have on the table some specimens of the different kinds of telegraph used. One is the needle instrument. If you send a current of electricity through a wire it deflects the compass needle. Thus a motion of the needle to the left first and then by reversing the direction of the current so as to deflect the needle to the right, we have the signal for letter A, and by combining the motions we can make up the letters of the alphabet. You can examine it afterwards. Here is the sounder which is founded upon the principle of the electro-magnet. There is an electro-magnet here with an iron keeper on the top of it. When a current is passing through it the keeper is pulled down, and makes a noise. Some of these sounds are made short and some long. Thus we may be in London, and are able to pass an electric current to Manchester, where the sounds will be received. Here is a Morse instrument, by means of which an electric current works upon the keeper, and directs a roller, and makes marks upon a strip of paper which is driven out by clockwork, and those marks are long and short, and the combination of the long and short ones makes up the combination of the letters, and so an operator in London is able to converse with an operator in Manchester. I have here a very beautiful apparatus, a device of Sir Charles Wheatstone. It is very largely used in this country, and it is the most perfect system of telegraphy that we possess. It is so rapid that it is impossible to send messages by hand quick enough, and the message has to be prepared by punching holes in a strip of paper, the holes in one side of the strip meaning short marks and those on the other side long marks. This punched paper is itself driven at great speed by clockwork, and another piece of clockwork here is driving another apparatus very similar to that which I showed you before. This apparatus is continually working over long distances between England and the provinces at the rate of 300 words a minute, and frequently up to 400 words a minute. The great advantage of this apparatus is that when you have the Queen's speech, for instance, punched out upon one of these strips of paper you can send it through one of these instruments first to Edinburgh, then to Manchester, and the same punched paper will be sent through a number of places in a very short time.

I will now briefly allude to the principle of the telephone so largely used, but I will only confine myself to-day to speaking of the Bell telephone, the same instrument being used to transmit the speech and also to receive it. The Bell telephone consists essentially of a magnet, with a soft iron terminal surrounded by a coil of wire. In front of this soft iron pole piece there is placed a disc of thin iron. When I speak against this disc of thin iron I cause it to vibrate in accordance with the sounds. Every time I speak it disarranges the magnetic conditions in the neighbourhood of the coil of wire, and we know that when that happens a current of electricity is set up in the wire, and thus every time this disc is spoken against a current of electricity is sent through the coil of wire to a distant station where the other person is listening. Here an exactly similar apparatus is used, and every time that the current of electricity varies either in direction or in amount it varies the attraction of the magnet for the disc of iron, and in proportion to the number of vibrations of the speaker against the disc which he is using, so are the number of vibrations which are listened to by the receiver. Consequently the sounds heard by the man who receives the message are identical in character with those which are spoken by the sender. I have no time to go more fully into a description of the apparatus, but I will simply say that this is one of the most marvellous applications of electricity yet known. It could hardly have been conceived possible that these minute vibrations would be sufficient to create currents of electricity which would go to such a distance. He concluded by giving practical illustrations of the use of the telephone and Mr. Edison's phonograph.

LEGAL INTELLIGENCE.

The Anglo-American Brush Electric Light Corporation v. Crompton.

In the High Court of Justice (Chancery Division), before Vice-Chancellor Bacon, on Friday last, this action came on for hearing. It was a motion for an interim injunction to restrain the defendants from infringing the patent taken out in 1878, and now held by the plaintiff company, for dynamo-electric machines. The defendants denied the alleged infringement, contending that the Brush patent had been anticipated by a previous patentee named Varley; and they sought by a cross motion to restrain the plaintiffs from infringing their patent, which was taken out in 1882, four years after the date of the original Brush patent, to which, however, amendments had been made at subsequent periods, bringing down the date of the patent as now existing to 1885. It appeared that by the invention of Mr. Brush, an American gentleman, a sufficient electric current to render lighting by incandescent lamps practicable was for the first time enabled to be generated. Dynamo machines, consisting of an armature cylinder of coiled copper wire, rotated at a high velocity, in conjunction with highly excited magnets, had formerly generated the required current on either of two principles—the "series" or the "shunt" systems. By the first the wires carrying the current were attached to the end of the rotating cylinder, the electricity thus passing in a circle. On account of the resistance the current thus met with, it was found that the motive power was not constant or sufficient for lighting purposes. By the "shunt" system the wires were attached in the same way, but were so coiled round the magnets that less resistance had to be overcome on the external circuit. Brush's patent, as described, comprised the coiling of both the external circuit and the shunt wires round the magnet, so that a higher motive was obtained.

Sir HORACE DAVEY, Q.C., for the plaintiffs, said that as conflicting evidence had been given on affidavits by eminent scientific men on each side, in accordance with the practice in such cases, the Court would not be asked to pronounce an opinion without seeing the deponents in the witness box, which, of course, could only be at the trial of the action. Accordingly, on condition of the defendants undertaking to keep an account of the number of machines sold by them made upon the compound winding principle of coiling both the shunt and series wires round the magnets, he motion would stand over until the trial of the action.

Mr. ROMER, Q.C., for the defendants, assented to the course proposed, but asked for a counter undertaking from the plaintiff company to keep an account of all machines sold by them made in infringement of the defendants' patent for keeping the potentials constant.

Sir HORACE DAVEY said the books kept by the plaintiff company would of course contain full accounts of all their business.

The VICE-CHANCELLOR ordered the motion to stand over until the trial of the action upon cross-undertakings being given by the defendants and the plaintiff company, the exact terms of the undertakings to be arranged between the parties.

The United Telephone Company v. St. George.

This was an action (tried before Mr. Justice Stirling on Saturday last) to restrain the infringement by the defendant (Mr. A. F. St. George, of 85, Chancery-lane, London), of letters patent No. 2,909, granted from July 30th, 1877, to Mr. T. Alva Edison for "improvements in instruments for controlling by sound the transmission of electric currents, and the reproduction of corresponding sounds at a distance." These letters patent are now vested in the plaintiff company. The plaintiffs allege that the defendant has infringed the patent since August, 1882.

Dr. Hopkinson, Mr. Imray, and other gentlemen, were called on behalf of the plaintiffs, and cross-examined at great length by the defendant, who conducted his own case.

The defendant having addressed the Court and called his witnesses, Mr. Justice STIRLING gave judgment for the plaintiff company, with costs.

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The 28th half-yearly general meeting of the shareholders in this Company was held on the 15th inst. at Winchester House, 50, Old Broad-street, under the presidency of John Pender, Esq.

The SECRETARY (Mr. George Draper) read the notice convening the meeting, and the report of the Directors, which has been published in *The Electrician*, was taken as read.

The CHAIRMAN said that the revenue for the half-year ended the 31st March had been £341,405, being a decrease of £30,277 as compared with the corresponding period of 1885. It would be observed on reference to the accounts that there was a decrease in the return from their investment in the South African Company of £1,950, that Company, owing to diminished receipts, having been able to pay a dividend of only 6 per cent., as compared with 7 per cent. in the previous year. Their Indian traffic had been fairly maintained, but the traffic to countries beyond India had declined since December last. The chief cause of their decreased receipts arose from the absence in the past half year of political and other events, which in 1885 augmented their Indian and Egyptian traffic to an exceptional extent. The total working expenses had amounted in the half year to £92,244, being an increase of £645 over the corresponding period of 1885. In the past half year, however, were included several items of an exceptional character, which he mentioned. These items came to £1,566. There was also charged to revenue account an amount of £1,788, the cost of duplexing the Zante-Alexandria cable. Excluding these exceptional items the total working expenses for this half year, as compared with the corresponding period of last year, would show a considerable decrease. The general expenses in London had been £8,773, or an increase of £1,156, mainly owing to their having removed to larger and more commodious offices, which they found were absolutely necessary to carry on the business of the Company, grown as it had within the last few years. The working expenses at stations had been £64,439, being a decrease of £2,143. The item "use of patents" showed a decrease of £1,600. The amount written off for depreciation of cable stores had been, in the half year under review, £4,200, against £2,795 in the corresponding period of 1885. They had carried £5,000 to maintenance ships' reserve fund, against £6,000 a year ago. The expenses attending repairs and renewals and laying of cables had amounted in the half-year to £41,637, being £3,178 less than in the same period of 1885. In abstract C, full details of the work done by their ships were given. Numerous important repairs had been effected, and in addition, the "Volta" had laid two new three-core cables across the Straits of Messina, the cost of which had been taken from revenue. A large part of the sum of £41,600, however, was due to the sudden breaking of both their Bombay cables in 800 fathoms during a cyclone. These were now repaired, of course, and in working order. After charging all expenses, including income-tax, providing for interest on debentures, debenture stock, and preference shares, they were enabled to pay a dividend of 5 per cent. with a bonus of 1 per cent., or at the rate of 6 per cent. per annum, and to carry to general reserve fund £70,000, leaving a balance of £4,079 to be carried forward to next account. He thought they would agree with him that upon the whole the accounts submitted by the Directors were very satisfactory. They were making a new departure with regard to rates, arising from the Conference held last year at Berlin. On all sides they heard it said, "Only reduce the rates and you will have a largely increased revenue." The Directors, however, thought that the risk ought not to be entirely with the Company. Governments even were interfering, and trying to get reduced rates. What the Directors were now endeavouring to establish, both at Australia and other parts, was a guarantee of such a rate of traffic or returns as they had been enjoying during the last three years. If they could succeed in that it would be giving practically a guaranteed rate to the proprietors in these companies, and at the same time it would be an enormous advantage to the different Governments and their telegraphing public, because they would be able to reduce the rates to an extent which it would be simply impossible for the Company to do without this guarantee. These negotiations were going on at present with Australia, and although looked upon with some little shyness, he thought that those who represented the colonies and those who had looked carefully into the matter were satisfied that that must eventually be the solution of the question of a reduction of rates. When that occurred the shareholders would practically be enjoying a guaranteed rate of interest upon their shares. He hoped that these negotiations would make such progress as would be very beneficial to the Company by-and-bye. Telegraphy, they might depend upon it, would grow as nations grew, and therefore he had no fear as to the calculations which were made by people who talked about their going back, and their stocks being reduced in value. There was no fear of their going back unless unnecessary and undue competition arose, and that was a matter which they would take as much care as possible to guard against. At the Berlin Conference, as he believed he mentioned last year, an important question arose about Egypt. He went out to Egypt in the spring and saw the Egyptian Government, and he was very pleased to say that that which they had supposed was going to result in a considerable annual payment from the Company to the Government had been entirely set aside. They were therefore in precisely the same position to-day as they were before they went to Berlin; and as they considered their position a very strong one, should the question arise again, if they had to give something, they would also get something in return. He thought that these visits to different Governments and stations abroad were calculated to do good in many ways. All their stations were in the most perfect order, and comparing them with the stations of other

Digitized by Google

nations they had reason, as Englishmen, to be proud. On the previous day they received a congratulatory message from the Governor of Sierra Leone, a circumstance which concerned a company with which they were in very close alliance—he referred to the Direct African Telegraph Company. Probably within two or three weeks the whole of that system would be completed, when it would become a feeder for the Eastern system from Lisbon. When the Direct African concession came before the Government there were some remarks made in the House of Commons by a gentleman who was interested in an opposition company, who desired a competing company with Australia. That gentleman admitted that if this Direct African concession were passed, it would be the death blow to his scheme, and as that scheme was perfectly uncalled for and unnecessary, he (the Chairman) was very glad to find that their concession was approved. It had passed through the hands of three English Governments, and he was pleased to find that the Secretaries of the Treasury of those Governments had defended the concession in the House of Commons in a way which must have been very unsatisfactory to those who had challenged it, but very satisfactory to those who were interested in it. He concluded by proposing a resolution for the adoption of the Report, the payment, less income-tax, of a dividend on the preference shares to June 30th, at the rate of 6 per cent. per annum, and the declaration of a dividend of 2s. 6d. per share, and a bonus of 1s. per share, both free of income-tax, on the ordinary shares, making, with previous payments by way of dividend on account, a total payment of 6 per cent. on those shares for the year ended March 31st last.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the resolution, which was carried unanimously.

On the motion of Mr. JOHN NEWTON a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN, in reply, stated that the Directors took very great pride in the progress and prosperity of the Company, and the shareholders might depend upon it that the Board would do all they could in the future to maintain its success.

The proceedings then terminated.

[We shall publish a full report of this meeting in our next issue].

The Direct United States Cable Company.

Report of the Directors for the six months ending 30th June last, to be presented at the eighteenth ordinary general meeting of the Company, held at Winchester House, 50, Old Broad-street (Room No. 174), on Friday, July 23rd. at 2 p.m.

The revenue for the half year, after deducting out-payments, amounted to £28,445. 0s. 9d., against £36,106. 1s. 1d. (after similar deductions) for the corresponding period of 1885, being a difference of £7,661. 0s. 4d., against the half-year under review, owing to the reduction of the tariff rate, mentioned in the eighth paragraph of this report. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cable, amounted to £15,866. 19s. 7d., leaving a balance of £12,578. 1s. 2d. as the net profit of the half year, making, with £5,967 1s. 3d. brought forward from the previous half year, a total of £18,545. 2s. 5d. For the corresponding half year of 1885 the working expenses and other payments amounted to £17,205. 15s. 11d., thus showing a reduction of £1,339. 16s. 4d. in favour of the present half year. Every possible economy has been exercised in the several departments of the Company's business. Three quarterly interim dividends of ¾ per cent. each, amounting to £27,319. 10s. 0d. have been declared and paid during the financial year, and a final dividend of 2s. per share is now proposed, making, with the three interim dividends, 2¾ per cent. for the year, being a total distribution of £33,390. 10s. The appropriation of the above balance of £18,545. 2s. 5d. on the revenue account is thus shown :—

Interim dividend for quarter ending 31st March, 1886.	£9,106	10	0
Final dividend now proposed	6,071	0	0
Carried to reserve fund	316	13	2
Carried forward to next account	3,050	19	3
	£18,545	2	5

During the current year the reserve fund has been increased by the interest on the investments, profit on sale of security, and sums transferred from revenue account, and now amounts to £325,000, after payment of the cost of repairs. A break occurred in the short section of cable on the 7th February last, and was repaired on the 18th of same month. On the 5th May last the tariff and that of the Associated Companies was reduced to sixpence per word to New York, and by arrangement with the Western Union Telegraph Company this reduction also applies to most of the principal places in the United States of America and Canada. For press news a special rate of threepence per word between London and New York has also been adopted. On the same date the tariff of the Mackay-Bennett cables was reduced to one shilling per word. So far the reduction has resulted in more than doubling the volume of traffic, and the Directors are not without hope that with a revival of trade it may be further increased. This alteration has not, however, developed a remunerative revenue. In the interests of the public and the proprietors the Directors desire to give the experiment such a continuous trial as will afford the commercial community the benefit of a permanent low rate, if it is likely within a reasonable time to yield a return commensurate with the capital employed, and the risks involved, in the establishment and maintenance of the system. Pursuant to the provisions of the Articles of Association, two of the Directors, viz., Admiral R. C. Mayne, C.B., M.P., and Charles Meara, Esq., retire by rotation, and being eligible, offer themselves for re-election. Mr. John G. Griffiths and Mr. John Sawyer, the auditors, retire pursuant to the Articles of Association, and offer themselves for re election.

CRICKET.

CARCAVELLOS C.C. *v.* VICTORIA C.C.

The above match (between the staff of the Eastern Telegraph Company at Quinta Nova, Carcavellos, and a Lisbon club) was played on the "Campo Pequeno," Lisbon, on the 2nd inst. At noon the Carcavellos commenced batting, the first five wickets falling for 23 runs, of which Mr. Bean contributed 12. On Messrs. Woodman and Freeman coming together runs came faster. At 38 Mr. Freeman was run out, after playing a steady game for his 15 runs. The innings closed shortly afterwards for 121. The Victorians in their first innings put together a total of 56, Messrs. Ferrie (16) and Rawston (12) being the highest scorers. Carcavellos in their second innings made 176, Messrs. Woodman, Lovell, and Bean showing up well. V.C.C. in their second innings scored eight runs for the loss of two wickets, when stumps were drawn. Scores :

Carcavellos, *1st innings.*—H. Hitchcock, c. Atkinson, b. Dalrymple, 0 ; H. Bean, b. Dalrymple, 12 ; E. V. Wyse, b. Alexander, 4 ; H. Musters, c. Maclaren, b. Dalrymple, 0 ; L. Woodman, not out, 59 ; F. Le Clair, run out, 1 ; R. Freeman, run out, 15 ; G. Lovell, b. Dalrymple, 0 ; J. Brereton, b. Dalrymple, 0 ; F. Noyes, b. Dalrymple, 9; R. Kidd, lbw., b. Giovetti, 0 ; extras, 21 ; total, 121. *2nd innings.*—L. Hitchcock, b. Alexander, 2 ; H. Bean, b. Dalrymple, 16 ; E. V. Wyse, run out, 5 ; H. Musters, b. Dalrymple, 0 ; L. Woodman, not out, 78 ; F. Le Clair, b. Dalrymple, 12 ; R. Freeman, c. Oram, b. Dalrymple, 3 ; G. Lovell, c. Maclaren, b. Limbert, 21 ; J. Brereton, c. and b. Alexander, 1 ; F. Noyes, b. Dalrymple, 6 ; R. Kidd, c. Maclaren, b. Giovetti, 3 ; extras, 29 ; total, 176.

V.C.C., *1st innings.*—M. Centeno, c. Woodman, b. Noyes, 0 ; R. Alexander, b. Brereton, 0 ; E. Dalrymple, c. Brereton, b Noyes, 0 ; H. Limbert, c. Lovell, b. Noyes, 1 ; T. Ferrie, st. Bean, b. Woodman, 16 ; G. Rawston, b. Brereton, 12 ; B. Oram, lbw., b. Wise, 7 ; R. Giovetti, b. Brereton, 5 ; T. Atkinson, c. Freeman, b. Woodman, 2 ; N. Maxwell, not out, 2 ; C. Maclaren, c. Brereton, b. Woodman, 3 ; extras, 9 ; total, 57. *2nd innings.*—R. Alexander, not out, 0 ; H. Limbert, c. Lovell, b. Bean, 0 ; T. Ferrie, not out, 3 ; T. Atkinson, b. Atkinson, 1 ; extras, 4 ; total, 8.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 16th inst. amounted to £2,790.

EDISON'S LABORATORY.—It is said that as a direct result of the strikes in New York City, Edison will remove his great machine plant from that city to Schenectady.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th inst. were £2,681, as compared with £2,554 in the corresponding period of 1885.

ROYAL SOCIETY.—The Electrical Power Storage Company have received the order to substitute a set of direct acting plant and accumulators for the existing alternating current machine in the installation at Burlington House.

THE TELEPHONE IN BELGIUM.—The Ostend district telephone system has, on the Van Rysselberghe plan, been connected with the Brussels central station, so that Brussels and Ostend subscribers, as well as the public by call offices, can inter-communicate.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 16th inst. were £2,209, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This company announce that the coupon on their 6 per cent. debentures due on 1st August will be paid after that date at the Consolidated Bank, Threadneedle-street, London, E.C.

LIGHTING AND HEATING THE NEW YORK STATE CAPITOL.—It is said that the finished portion of the New York State Capitol at Albany has over 30 miles of gas, water, and steam pipes, and that the annual cost of lighting the building (gas and electric lighting) is 20,000 dollars.

INTERNATIONAL SOCIETY OF ELECTRICIANS. — The *Proceedings* of this society are, in future, to contain a chronicle of the work of the month, and all those engaged in pure or applied electrical science are invited to send a note of their work before the 15th of each month.

HOLLOWAY COLLEGE.—Messrs. Verity and Sons inform us that the cables for the electric lighting for the college were manufactured by the Callender's Bitumen and Telegraph Company, and not by the India Rubber and Gutta Percha Company, as mentioned in our report.

THE WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.—We are informed that this company, at a Board meeting held on the 9th inst., declared an interim dividend on its preference shares of 3 per cent. for the half year ended the 30th June last (*i.e.* at the rate of 6 per cent. per annum).

EDUCATIONAL.—It is stated that a school has been founded at St. Petersburg specially for the study of electrical subjects, and that the student who successfully passes the examinations receives the title of "Maitre en Galvanoplastie." We have M.A.'s, B.A.'s, &c.; perhaps to these will soon be added M.G.'s.

TEMPORARY LIGHTING.—During the last few days the Electrical Power Storage Company have lit Grosvenor House for the Duke of Westminster on two occasions. They also carried out the lighting of the Indian Room at the ball given by H.R.H. the Prince of Wales, on the 21st inst., at Marlborough House.

ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the Board of Directors of the Anglo-American Telegraph Company, held on the 16th inst., it was resolved to place the sum of £25,000 to the credit of the renewal fund for the quarter ending 30th June, 1886, and to carry forward the balance of revenue account, amounting to £2,400.

LIGHTING OF OFFICES IN THE CITY.—In view of the successful working of several installations of the electric light in the City in conjunction with accumulators, the North British and Mercantile Insurance Company have decided to have their offices lit throughout, and have given the order for this work to the Electrical Power Storage Company, of 4, Great Winchester-street, E.C.

THE ELECTRIC LIGHT IN AFRICA.—The first African city lighted by electricity was not Algiers or Cairo, but Kimberley, with forty-two Brush lamps, each of 2,000 candle-power. The current is also used there for the killing of dogs—a step suggesting the execution of death sentences by the same means, as proposed in America and France by M. Charson, a member of the Senate.

THE CHARGE FOR TELEPHONE WIRES.—At the last monthly meeting of the members of the Bolton Town Council it was stated that an arrangement had been made with the Telephone Company that for each wire attached to any property of the Streets Committee, or to any pole of the same department fixed on land, 1s. per wire per annum would be charged whatever length and number of attachments there might be.

TAUNTON.—We understand that the electric light is giving so great satisfaction that the energetic proprietor, Mr. H. G. Massingham, has decided to double the plant, and has given an order to Messrs. Laing, Wharton, and Down, the agents in England for the Thomson-Houston system, to supply a 30-light machine by September next. The lighting, which we recently described, has now been going for more than three months without a single hitch.

THE ELECTRIC LIGHT V. GAS.—One of the signal services which electricity has conferred on the public has been to lower the price of gas in all places where any serious effort at competition with the latter has been attempted. This fact is abundantly manifest just now in some of the principal towns of the United States and France, where the popularity of the electric light for street lighting is causing the gas companies no end of uneasiness, and inducing them to atone for their errors in the past by greatly reducing their charges.

THE EASTERN AND SOUTH AFRICAN COMPANY. — The seventh ordinary general meeting of this company was held on Tuesday last, John Pender, Esq., in the chair, when, after an explanation of the position of the company, and of several exceptional demands upon revenue, it was agreed to declare a dividend, amounting, with the previous interim dividends, to 6 per cent. per annum, and to carry to general reserve fund £17,000. The cost of the Mozambique-Zanzibar section has been paid out of the general reserve fund.

TELEPHONE EXTENSION AT SWANSEA.—The number of wires which already span the streets of Swansea is very considerable, and shows the stranger at a glance that advantage is now being pretty freely taken by the business portion of the community of the facilities for the quick communication offered by the telephone. The Western Counties and South Wales Telephone Company have recently taken the premises

Digitized by Google

in Wind-street as an exchange. This week their first instruments have been got into position and working order.

ELECTRICAL MACHINES.—Messrs. R. E. Crompton and Co have just sent out several very large dynamos. Three immense shunt machines, giving 110 volts and 325 amperes, have been sent to the Small Arms Factory, Enfield; and the firm are supplying the dynamos for lighting up the Surrey residence of the Right Hon. W. H. Smith. They are also making twenty-two sets of machines for the torpedo search lights for the Admiralty, and two machines giving 80 volts and 500 amperes for the Prudential Assurance Company. These machines weigh about 3¼ tons each.

THE ELECTRIC LIGHT IN BUDA PESTH.—The company formed for the construction of Ganz and Co's machines at Buda Pesth has made an offer to instal the electric light in the principal streets and squares of that city. The chief conditions which it demands are:—1st, a concession of ground for the erection of a central station; 2nd, the establishment of water conduits to feed the machinery; 3rd, a concession to work for 20 years, with the right at the expiration of the gas company's concession to supply the electric light to private houses; and, 4th, the payment of a rent of 16 kreutzers per lamp per hour.

THE BRITISH ASSOCIATION.—The British Association having selected Birmingham for the next annual meeting in September, much local effort is being directed towards making the meeting a success to the association and a credit to the town. An exhibition of local industries is to be held in the Bingley Hall, the project having met with so much support that the space at the disposal of the committee of management has all been appropriated, a large number of would-be exhibitors being turned away. The hall, as we have previously stated, will be illuminated with the electric light, partly arc and partly incandescent.

ELECTRICAL ALARM FOR A CABLE ROAD.—In view of the liability of accidents in the running of cable cars the Philadelphia Traction Company is introducing a new electrical system on their Market-street branch. The plan consists in laying leaden tubes containing telegraph wires alongside the conduits, and a simple alarm box will be placed in each manhole along the route of the cable cars. This affords instant communication with the engine-house at Twentieth-street, and when an accident occurs to the cable, necessitating the stoppage of the engine an alarm can be sent at once to the station, and through an arrangement of signals any information that is needed to meet the emergency can be instantly forwarded.

AN ELECTRIC LIGHT SCARE.—Early last week, during an experiment with the electric light at the mills of Mr. J. Walsh, J.P., in the neighbourhood of Blackburn, where scientific knowledge is somewhat behind the times, people from all parts of the town, concluding that the mills were on fire, eagerly rushed in their thousands to the scene of the supposed conflagration. The general alarm soon reached the fire engine station, and a steam fire engine was manned and was soon on its way to the spot, where the firemen no doubt hoped to distinguish themselves in subduing a fire of uncommon proportions. They had, however, proceeded no farther than the police station when they were met and politely informed of the nature of the unusual illumination at the mills.

CREMATION BY ELECTRICITY.—An electrical crematory is said to have been devised by a process described as follows:—The body being shrouded in sheets made of asbestos is laid upon a frame composed of fire brick, while at the head and foot are large copper plates, to which the leads from specially constructed dynamos of large E.M.F. are attached. The body apparently occupies the position of the filament in an incandescent lamp, and upon the current being passed through it would be instantly carbonised, while, as the air would have free access to it the process of destruction, or rather decomposition, would be immediate. The process appears to have the recommendation of great rapidity of action, and immunity from many of the objections to cremation in the ordinary way.

PRIMITIVE TELEPHONES.—The *Scientific American*, discussing this subject, describes and illustrates certain primitive telephones before the era of Bell's patent. In reading these and similar articles, and, in fact, whenever considering information relating to early investigations and designs of apparatus, one thing should be kept clearly in mind, that although from an historical and scientific point of view it is very interesting to have the truth, the whole truth, and nothing but the truth as to the original discoverer and the development of an invention, it is as interesting to know the man or men who made the discovery commercially successful. Returning to the article, it describes a magnetic telephone constructed by A. Holcomb in 1860-61, one by Beardsler of date before 1865, and Van der Weyde's instruments of 1869 and 1870.

LORD NORTHBROOK'S SOIRÉE AT THE COLINDERIES.—On Wednesday evening, after the Exhibition was closed to the public, Lord Northbrook gave a *soirée* in portions of the Exhibition, which were specially illuminated for the occasion by about seven hundred 5-candle incandescent lamps. These required no additional dynamo or engine power beyond the ten Edison and Hopkinson machines made by Mather and Platt for the Edison-Swan Company, two of which, however, are engaged in charging accumulators for lighting the subway and quadrant dining rooms. Under the superintendence of M. Schultz, festoons of white lamps, enclosed in Chinese lanterns, enlivened the tea gardens; a line of red lamps marked out the ballustrade, and green lamps the steps leading to the higher level. The lamps were coloured by simply dipping them in varnish impregnated with Judson's dyes.

A.A.A.S.—These letters are the American equivalent to our B.A. We are apt to speak of the British Association as the B.A., and the meeting as the B.A. Meeting—though it was not to discuss letters that we commenced this note. The B.A. meeting is due within a few weeks, but so far as we know the volume of the *Proceedings* of the 1885 meeting are not yet issued. Some few years back, during the secretaryship of Mr. Gordon, a great and a fairly successful effort was made to issue the *Proceedings* within a reasonable time of the meeting, but latterly the old plan of procrastination has gained ground. However, it may be said that in America they in this case are no better, for the two vols. of the *Proceedings* of the A.A.A.S. for 1884 are but just to hand. If the world depended upon the issue of the *Proceedings* of some of the scientific societies for information as to the progress made, the world would roll upon its axis for a year or so before getting authentic information. Perhaps in this age of hurry our scientific captains take this method of teaching us to "bide a wee and dinna weary."

THUNDERSTORMS.—On Wednesday the Liverpool district was visited by heavy thunderstorms. In the low-lying parts of Liverpool much damage was caused by floods in the basements of business premises. In some cases the city fire engines were employed to pump out the water. The residence of Dr. Wiskin and a cottage in Cobden-street, Heywood, were struck by lightning. The roof of Dr. Wiskin's house was smashed, and the chimney of the cottage was split from top to bottom. The heavy downpour of rain flooded many villages in the district round Kirkby Stephen, Westmorland, and laid hundreds of acres of meadow land under water, inflicting

Digitized by Google

great losses on farmers. The Channel Squadron, consisting of the "Minotaur," "Agincourt," "Monarch," and "Iron Duke," with torpedo boats Nos. 23 and 24, which were to have left Queenstown last Monday, are still detained there owing to the severity of the weather. A gale from the south-west is blowing, and incoming steamers report a heavy sea on the coast. At Durham a farm bailiff named Smurthwaite, employed by Messrs. Ferens and Love, colliery owners, was killed by lightning.

DAMASCENING BY ELECTROLYSIS.—A method of damascening by electrolysis has recently been brought out in France. Two copper plates are put into a bath of sulphate of copper solution, one being connected with the positive pole and the other with the negative pole of a battery. A thin layer of insulating varnish or wax is spread over one of the copper plates, viz., that connected to the positive pole, and the damascened device is etched on it. Now, since copper is by electrolysis transferred from this plate to the other plate, it follows that only the lines of the drawing can be attacked. A battery of two cells is sufficient for the pupose. When the plate has been bitten to the depth of a millimetre it is removed from the bath and treated with hydrochloric acid to remove traces of oxide of copper in the lines of the drawing. It is then washed with water, and suspended in a bath of nickel and silver, and connected with the negative pole of the battery. The positive pole now consists of a plate of platinum. The silver or nickel deposits wherever the copper has been attacked, and the depressions are soon filled with the foreign metal; the plate is then polished, and looks like one which has been damascened by hand.

WHO WAS THE INVENTOR OF THE TELEPHONE?—This question has been revived, and has recently been giving rise to a good deal of correspondence in the newspapers, and like all subjects of the kind it will doubtless give rise to a good deal more before it is settled to the satisfaction of everybody. But whoever had the honour of discovering the principle of the telephone, the Italians seem recently to have taken a step which ought to solve the problem for all time. Not content with possessing Galvani, Volta, and Pacchinotti in their niches of electrical fame, they have just erected a statue at Aosta which bears the following significant inscription: — "Innocenzo Manzetti, Inventor and Maker, in the year 1864, of the first Telephonic Apparatus, in occasion of the Inauguration in 1886 of the railway line uniting Italy with the old town of Aosta. The Association of Mechanical Industry and Kindred Arts of Turin." What the Americans will have to say to this in their patronage of Bell, and the Germans in view of the discovery made by Philip Reis at Frankfurt in 1858, may be looked forward to with some interest.

UNDERGROUND CABLES AND HIGH TENSION CURRENTS.—Reverting to the articles which appeared in *The Electrician* of June 18th and 25th upon the subject of the use of high tension currrents with underground cables, it may be of interest to note that the difficulties which were therein referred to do not complicate the problem of electric lighting so much as at first sight would appear. At Nigmegen, recently, the firm of Messrs. William Smith and Co. have completed an arc light installation consisting of ten lamps, fed by underground lead-covered cable, 4,000 metres in length. The cable is protected outwardly by a kind of braiding, while the core (12 strands No. 16) is insulated by several layers of india rubber, manufactured at Silvertown. The wire is laid in the streets at a depth of 2ft., without having any other outward protection. The strength of the current is 18 amperes, with an E.M.F. of from 500 to 600 volts. It would of course be premature to pronounce any decided opinion as to the ultimate results of the use of a cable in this way, but up to the present it has been satisfactory—a state of things which, being so intimately bound up with the future success of the electric light, it is to be hoped will continue.

SOCIETY OF ARTS CONVERSAZIONE.—By permission of the Royal Commission, this agreeable *fête* was held in the Colonial and Indian Exhibition on Friday evening, 16th inst., being one of the two evenings reserved from season ticket holders and the public. The visitors were received in the Indian Court by Sir Frederick Abel, C.B., F.R.S., and the members of the Council. Besides the usual "attractions" of the Exhibition, including Col. Sir Francis Bolton's Art Waterworks, now illuminated by fifteen arc lamps with holophotes, and the Geyser-like effect produced by volumes of steam, the bands of the 1st West India Regiment, of the Grenadier Guards, and of the Royal Horse Guards, discoursed most excellent music, as also did the Criterion Glee Choir and the Royal Hand-bell Ringers. There was no extra lighting in the building, but in the gardens were festoons of 10-candle incandescent lamps, enclosed in Chinese lanterns, which produced a very happy effect. These five or six hundred extra lamps, in addition to the usual number of 11,800, made so little demand upon the four Elwell-Parker dynamos that the accession of resistance was scarcely noticed. On wet nights, however, when there is a considerable leakage, these machines have enough to do to maintain the lighting.

ELECTRICITY AT HATFIELD.—Readers of *The Electrician* need scarcely be reminded of the great practical interest which the Marquis of Salisbury takes in electrical science, for in times past we have frequently had occasion to refer to the excellent installation of the electric light which has been put up at his palatial residence at Hatfield. Amid all the cares of statesmanship and the excitement of party conflict the leader of the Conservative party has yet found some time to devote to the study and practical application of electricity, and perhaps to him is due, more than to any other, the credit of showing to the world the efficiency of the electric light as a household illuminant. A fresh illustration of the uses of electricity and of the undiminished enthusiasm of the noble marquis for making this great force of nature subservient to the purposes of every day life may be found in the fact that it has recently been applied with great success to an ordinary grass cutter. At one of the farms on the estate, it appears, ensilage is being stored in large quantities; and it having been decided to chaff the grass it was necessary to place the cutter some feet above the ground, and now a Siemens motor drives an elevator and the chaff cutter by means of power generated by a Brush machine from the River Lea, a mile and a half distant.

VOLTAMETERS V. ACCUMULATORS.—M. Emile Reynier suggests the use of voltameters of zinc and lead in place of secondary batteries of the Faure type for the regulation of electric lighting. He shows that incandescent lighting direct from dynamos can never be absolutely uniform, because of the inherent irregularities of the driving and generating machinery. These variations are more or less marked, according to the degree of perfection of the installation; and more or less endurable according to the nature of the service required. In the case of lighting by incandescence, small alterations of velocity produce great variation of brilliancy in the lamps; the luminous intensity being nearly proportional to the sixth power of the difference of potential between the two branches of the distributing service. Accu-

Digitized by Google

mulators, as is known, render the current sensibly regular, because their electromotive force varies much less than that of the machines which charge them. The great objection to the use of accumulators for this purpose is that the regularity they bestow costs too much. Hence M. Reynier suggests in *La Nature* that for the office of flywheel, as distinguished from that of gasholder, the voltameter may supplant the accumulator. The regulating power of a secondary battery does not depend upon its electro-chemical capacity, but upon its regularity of discharge.

Underground Wires.—The question of overhead and underground wires may be said to have been fought out to the bitter end by our friends across the Atlantic. A few years has sufficed for public indignation to compel the authorities to take effective action. Overhead wires are condemned, and the larger towns will have none of them. The action taken in Chicago and New York is certain to be followed up. Vested interests will count as nothing in America. The order goes forth—"Get rid of your overhead wires, or we will get rid of them for you." What a pity it is we have not some strong hand to do the same thing in London. The supporters of overhead wires have fought gamely in America, and must acknowledge themselves fairly beaten. Chicago and New York have tried lots of systems, and at last have definitely decided to adopt that of Mr. David Brooks. We are glad to hear of this, as since our introduction to the system in 1881 we have ever thought it presented a way out of the difficulty of overhead wires. Mr. Brooks has himself been to Chicago to arrange the work there. The contract with the Bell Telephone Company is for laying about 2,000 miles of wire underground. The work will be begun some time in September and will be completed in about thirty days. The wires will be laid in three trunk lines in three of the principal streets. A three-inch pipe, containing five hundred wires, will be laid, and at every cross street twenty wires will be switched off for the accommodation of the customers along that street. The number of wires will therefore diminish as the distance increases, until, at the end of two miles and a half from the starting point, only 100 wires will remain. These will be put on poles, forming lines to the suburban towns. Mr. Brooks says poles and lines are rapidly disappearing in Chicago itself. There is not a pole carrying electric light wires on the streets, a state of affairs differing very widely from that existing some few months ago.

Heating Foot-Warmers by Electricity.—M. Tomasi, says the *Proc.* Inst. Civil Engineers, has introduced an improvement in the plan for heating foot-warmers for railway carriages with acetate of soda, by causing a current of electricity to pass through the liquid solution in such a way as to produce an increase of temperature, and so maintain the heat lost by radiation. The current generated by a dynamo, driven from one of the axles of a luggage-van, is sent through a circuit which extends from one end of the train to the other, and from this main circuit the branch conductors that pass through each foot-warmer in a longitudinal direction are connected. The foot-warmers, which are previously filled with acetate of soda, hyposulphite of soda, or some other salt of soda, having the property of maintaining a large amount of latent heat, which is disengaged when passing from a liquid into a crystalline state, are before starting plunged into boiling water, and when sufficiently heated, placed in the carriages, and connected with the circuit. When the train is stopping no effect is produced, but as soon as a sufficient speed is attained the electric current, generated by the dynamo, traverses each foot-warmer, and the conductor in it being of less section than the one outside, a greater amount of resistance is offered to the passage of the current, and in consequence heat is produced, and is communicated to the solution, replacing that which has been lost by radiation in warming the vehicle. The quantity of latent heat in the solution being considerable, a stoppage of even three hours is not capable of producing such a cooling effect as to render necessary its being reheated by other means beyond that described; therefore, a train may travel from Calais to any part of Europe without there being any necessity to change the foot-warmers. It will readily be seen from this the great advantage that such a system offers, both to railway companies and to passengers; in the first place fewer foot-warmers are required, a saving in the cost of labour, maintenace, fuel, &c.; whilst, in the second, the comfort of the latter is at the same time increased. A simple arrangement by which the conductor in the foot-warmer is thrown out of circuit, when too hot, provents any danger from overheating.

Electric Traction of Vehicles.—The following, according to the *Revue Internationale de l'Electricité*, is the problem which M. J. B. Berlier has set himself to solve. A good means of transmitting the electric energy by means of conductors running along the road to a light motor placed on the vehicle, this electric energy being produced in a factory at the terminus. This transport of electric energy has its difficulties, as is well known. There must be all along the way two continuous sliding contacts, and it is on their quality and constancy that the progress of the carriage depends. If contact is broken on one of the two conductors the carriage is forcibly stopped. Again, there is the difficulty of leakages, especially with underground lines, and aerial lines supported by posts are objectionable to the eye, so that the underground lines will have to be the ones permanently used where artistic effect is important, as in Paris. For tramways the use of the rails has been suggested, well insulated as conductors, but it is easily seen that in towns, which are the chief centres of these installations, the suggestion is hardly practicable. Passengers and horses are exposed to electric shocks, which are annoying even when not dangerous, and a bar of metal placed so as to join the rails closes the circuit and stops the service. Underground passages, which meet the mass of principal objections, present difficult conditions; contacts with the earth are to be dreaded, and the keeping in working order is difficult. M. J. B. Berlier suggests that the rolling way consist of two hollow cast metal rails; each of these supports two steel rails, shaped in section like mushrooms, leaving between them a longitudinal interval for lodging the flanges of the wheels and the passage of the stalks of the collector of the current and of the scrapers and brooms. The rails are fixed to the upper part and suitably wedged along a cast metal trench which traverses the whole length of the road. It is in this trench, and under the shelter formed by a projecting part, that the conductor is mounted on an insulating support. The mud and dirt of the street which fall into the trench through the groove are driven along by scrapers and brooms to conduits placed at intervals and communicating with the drains. The aim of these arrangements is to prevent the mud from reaching the conductor, and ensure the cleanness of the trenches by flushing. The current arrives at the motor under the carriage by means of a collector mounted on a light frame on the axles, so that its relative height does not vary and contact is insured. The contact piece carries at its lower end a spring or some other arrangement to force the collecting brush to rub constantly against the conductor. The current is brought back to the generator by a similar arrangement on the other side.

REGISTERING FREE PENDULUM OSCILLATIONS.—M. Marcel Deprez has recently presented to the French Academy a very interesting note upon the above subject. He says: It is well known that the problem of determining the force of gravitation in a given locality is practically reduced to that of obtaining the period of oscillation of a free pendulum. It is therefore a matter of some importance to perfect the means of timing the swing of such a pendulum with the utmost accuracy. The only method which can be employed in practice is to count the number of oscillations during a given period, the pendulum being allowed to swing with absolute freedom. Then the longer the experiment lasts the more accurate will be the result, but at the same time the greater will be the fatigue of the observer. It would therefore be very convenient, if it were possible, to construct an apparatus which should register the number of oscillations, after the manner of the mechanical speed counters, but which should at the same time fulfil the condition *that it should not exert any mechanical action upon the pendulum.* It is evident that this is a problem which can only be solved by the employment of some optical method. M. Deprez proceeds to say that the first idea which suggested itself to him was based upon the employment of a mixture of hydrogen and chlorine, which, under the action of a reflected light ray, produces an explosion at each swing of the pendulum. He did not, however, see his way to the construction of a practical apparatus upon this principle. M. d'Abbadie then suggested that the reflected ray might be caused to fall upon a selenium wire traversed by an electric current. The resistance of the selenium would thus undergo a periodical variation, synchronous with the swing of the pendulum, which variation might without much difficulty be made to control an electro-magnetic counter. This method was not, however, adopted because it was not known whether or not the resistance of the selenium would vary with sufficient rapidity. Finally, M. Deprez has determined to adopt the following plan, which although not yet put in practice, does not seem to present any special difficulty:—It is well known that the action of the thermopile under radiant heat is not only characterised by excessive delicacy, but is also well nigh instantaneous. The pendulum is therefore mounted behind a screen, which is provided with a long and narrow slit in the vertical direction. In front of this slit is placed a "linear" thermopile, consisting of a single vertical row of elements. Upon the same side of the screen as the pendulum is a petroleum lamp with a flat wick. The lamp is placed in such a position that its rays, after traversing a cylindrical lens, fall upon the pendulum, and are thence reflected upon the face of the thermopile. At each oscillation, therefore, a current will be generated in the pile. The current is caused to pass through the coils of a very sensitive but extremely dead-beat galvanometer. The deflection of the needle thus reproduces the swing of the pendulum. The needle is caused to act as the tongue of a relay, and closes the circuit of a more powerful battery, which actuates an electro-magnetic counter. In this way it would be possible to obtain an automatic record of the number of vibrations of a free pendulum during any required period.

AN ENGLISH TELEGRAPH VICTORY.—We congratulate Mr. Thomas Fuller, the managing director of the Brazilian Submarine Company, on the great victory he has just scored in Paris for the English telegraph industries. That company is one of the most prosperous telegraph corporations here. It holds a privilege, which will last seven years longer, of telegraphic communication between Brazil and Europe, and besides propping up the Western and Brazilian Company, to which it hands over one-third of its receipts, it has made money enough to pay 7 and 8 per cent. on the enormous capital of £1,300,000, besides £150,000 of debentures, and to build a duplicate cable, taking for the purpose upwards of £500,000 from the reserve fund. In every respect the Submarine is a strong company, and its shareholders include many strong and influential people. Some time ago an American company, the D. Pedro II., undertook to lay a cable between Brazil and Trinidad, there to connect it with the lines of the West India and Panama and the Cuban Submarine to Florida. But, as the West India and Panama refused any traffic agreement whatever with the D. Pedro II., the latter looked elsewhere for a footing in the Antilles, and found it in San Domingo, where a French company was in possession of a valuable privilege. That company lately proposed to reorganise itself and lay cables to Cayenne, which is now isolated, Martinique, Guadaloupe, Curacoa, and Venezuela, and from San Domingo, directly to some convenient point in the United States. The French Government agreed to guarantee a large sum of money as interest upon the capital, and the Government Bill, signed by President Grévy and three Ministers, came before the Chambers a few days ago. It had been approved by the committee of the Budget, and the Government considered it so important that it asked urgency for its consideration. It must be a matter of congratulation for the Submarine, Western and Brazilian, West India and Panama, and the Maintenance and Construction Companies, that the Chambers by a majority of six votes in 510 refused the urgency. The result is due to the excellent generalship of Mr. Fuller and his French aide-de-camp, M. Despecher, said to be a man of remarkable sagacity, who has certainly made good use of the influence of the four companies at his back, and enlisted in their service the prestige of one of the most respectable of Parisian papers. M. Granet must feel very humiliated, but he deserves no better luck. His scheme is absurd and costly. It is based on the sentimental idea that France must have French cables to French colonies, and should have cables built in France. For that vanity France must pay heavily when the West India and Panama has lines to Martinique and Guadaloupe, and when Cayenne can easily be linked to the British cable in British Guiana. And as to having the cables built in France, it is another sickly "sentimentalism." Our companies have not enough to do, and can build cheaper cables than any new companies in France. The most important of the English companies have made most of the cables of the world, and it is not in vain that their stock is quoted at 150 per cent. and 250 per cent. premium over par value. It is also true that the success of the German factory in Hamburg, which has turned out one of the best cables in existence, the Bennett-Mackay, is a well-assured fact. But all that does not prove that the Société Téléphonique should now embark in an enterprise that is so wholly useless. In the meantime we wish to give a word of warning to our English companies. The Brazilian Submarine has kept up outrageous tariffs for Brazil. Till a few days ago it cost an American coffee merchant 11s. 4d. to wire a word from New York to Rio de Janeiro. The rate is now lower, owing to the cable war and to the lowering of the submarine tariff a few weeks ago, and after the French Government Bill became known. Indeed, up to a short while ago, it cost more to send a message to semi-barbarous Paraquay, 100 miles south of Rio, than to the capital of the Brazilian Empire. No wonder that the Brazilian Government and people detest the English monopoly. The Submarine has certainly killed the French Government Bill, and their contract with Count d'Oksza and his companies; but it should use its great victory sparingly. It should do something for the public. It has already done enough for its enormously-swelled capital.—*The Financial News.*

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.—XXIX.

BY OLIVER HEAVISIDE.

(Continued from page 139.)

Oscillatory impressed force at one end of a line. Its effect. Application to long distance telephony and telegraphy.

Given that there is an oscillatory impressed force in a circuit, if this question be asked—what is the effect produced? the answer will vary greatly according to the conditions assumed to prevail. I therefore make the conditions very comprehensive, taking into account frictional resistance, forces of inertia, forces of elasticity, and also the approximation to surface conduction that the great frequency of telephonic currents makes of importance.

Space does not permit a detailed proof from beginning to end. The results may, however, be tested for accuracy by their satisfying all the conditions laid down, most of which I have given in the last three sections.

The electrical system consists of a round wire of radius a_1, conductivity k_1 and inductivity μ_1; surrounded by an insulator of inductivity μ_2 and specific dielectric capacity c, to radius a_2; surrounded by the return of conductivity k_3, inductivity μ_3, and outer radius a_3. The wire and return to be each of length l, and to be joined at the ends to make a closed conductive circuit.

Let S be the electrostatic capacity, and L_0 the inductance of the dielectric per unit length of the line. That is,

$$L_0 = 2\mu_2 \log (a_2/a_1); \qquad S = c/2 \log (a_2/a_1). \quad . \quad (33b)$$

We have $L_0 S = c\mu_2 = v^{-2}$; if v is the speed of undissipated waves through the dielectric.

Let V be the surface potential of the wire, and C the wire current, or total current in the wire, at distance x from one end at time t. The differential equation of V is

$$\frac{d^2V}{dx^2} = (R' + L'p)SpV; \quad . \quad . \quad . \quad . \quad (34b)$$

where R′ and L′ are certain even functions of p, whose structure will be explained later, and p stands for d/dt. That of C is the same. The connection between C and V is given by

$$-\frac{dV}{dx} = (R' + L'p)C \quad . \quad . \quad . \quad . \quad . \quad (35b)$$

Both (34*b*) and (35*b*) assume that there is no impressed force at the place considered. If there be impressed force e per unit length, add e to the left side of (35*b*), and make the necessary change in (34*b*), which is connected with (35*b*) through the equation of continuity

$$-\frac{dC}{dx} = SpV \quad . \quad . \quad . \quad . \quad . \quad . \quad (36b)$$

But as we shall only have e at one end of the line, we shall not require to consider e elsewhere.

Now, given (34*b*) and (35*b*), and that there is an impressed force $V_0 \sin nt$ at the $x = 0$ end, find V and C everywhere. Owing to R′ and L′ containing only even powers of p, and to the property $p^2 = -n^2$ possessed by p in simple harmonic arrangements, R′ and L′ become constants. The solution is therefore got readily enough. Let

$$\left.\begin{aligned} P &= (\tfrac{1}{2}Sn)^{\frac{1}{2}}\{(R'^2 + L'^2n^2)^{\frac{1}{2}} - L'n\}^{\frac{1}{2}}, \\ Q &= (\tfrac{1}{2}Sn)^{\frac{1}{2}}\{(R'^2 + L'^2n^2)^{\frac{1}{2}} + L'n\}^{\frac{1}{2}}. \end{aligned}\right\} \quad . \quad . \quad (37b)$$

These are very important constants concerned. Let also

$$\left.\begin{aligned} \tan\theta_1 &= (L'nP - R'Q)/(R'P + L'nQ), \\ \tan\theta_2 &= \sin 2Ql/(\epsilon^{-2Pl} - \cos 2Ql). \end{aligned}\right\} \quad . \quad . \quad (38b)$$

These make θ_1 and θ_2 angles less than 90°. Then the potential V at distance x at time t is

$$V = V_0\epsilon^{-Px}\sin(nt - Qx) + V_0\frac{\epsilon^{Px}\sin(nt + Qx + \theta_2) - \epsilon^{-Px}\sin(nt - Qx + \theta_2)}{\epsilon^{Pl}(\epsilon^{2Pl} + \epsilon^{-2Pl} - 2\cos 2Ql)^{\frac{1}{2}}}. \quad (39b)$$

and the current C is

$$C = V_0\frac{(Sn)^{\frac{1}{2}}}{(R'^2 + L'^2n^2)^{\frac{1}{4}}}\left[\epsilon^{-Px}\sin(nt - Qx - \theta_1) - \frac{\epsilon^{Px}\sin(nt + Qx - \theta_1 + \theta_2) + \epsilon^{-Px}\sin(nt - Qx - \theta_1 + \theta_2)}{\epsilon^{Pl}(\epsilon^{2Pl} + \epsilon^{-2Pl} - 2\cos 2Ql)^{\frac{1}{2}}}\right] \quad (40b).$$

Each of these consists of the sum of three waves, two positive, or from $x = 0$ to $x = l$, and one negative, or the reverse way. If the line were infinitely long, we should have only the first wave. But this wave is reflected at $x = l$, and the result is the second term. Reflection at the $x = 0$ end produces the third and least important term.

The wave speed is n/Q, and the wave length $2\pi/Q$. As the waves travel their amplitudes diminish at a rate depending upon the magnitude of P. The angles θ_1 and θ_2 merely settle the phase differences. The limiting case is wave speed $= r$, and no dissipation.

The amplitude of the current (half its range) is important. It is

$$C_0 = \frac{V_0(Sn)^{\frac{1}{2}}}{(R'^2 + L'^2n^2)^{\frac{1}{4}}}\left[\frac{\epsilon^{2P(l-x)} + \epsilon^{-2P(l-x)} + 2\cos 2Q(l-x)}{\epsilon^{2Pl} + \epsilon^{-2Pl} - 2\cos 2Ql}\right]^{\frac{1}{2}},$$

at any distance x. At the extreme end $x = l$ it is

$$C_0 = \frac{2V_0(Sn)^{\frac{1}{2}}}{(R'^2 + L'^2n^2)^{\frac{1}{4}}}(\epsilon^{2Pl} + \epsilon^{-2Pl} - 2\cos 2Ql)^{-\frac{1}{2}}. \quad . \quad . \quad (41b)$$

As it is only the current at the distant end that can be utilised there, it is clear that (41*b*) is the equation from which valuable information is to be drawn.

It must now be explained how to get R′ and L′, and their meanings. Go back to equation (28*b*), section XXVII., p. 89, which is the determinantal or differential equation when dielectric displacement is ignored. We may write it

$$0 = L_0p + \frac{\rho_1 s_1}{2\pi a_1}\frac{J_0(s_1a_1)}{J_1(s_1a_1)} - \frac{\rho_3 s_3}{2\pi a_2}\frac{J_0(s_3a_2) - \frac{J_1}{K_1}(s_3a_3)K_0(s_3a_2)}{J_1(s_3a_2) - \frac{J_1}{K_1}(s_3a_3)K_1(s_3a_2)}.$$

When p is d/dt it is the differential equation of the boundary magnetic force, or of C, since they are proportional. Separating into even and odd powers of p it will take the form, if we operate on C,

$$0 = (R' + L'p)C \quad . \quad . \quad . \quad . \quad . \quad (42b)$$

where R′ and L′ are functions of p^2. To suit the oscillatory state, put $-n^2$ for p^2, making R′ and L′ constants. They will be of the form

$$R' = R'_1 + R'_2; \qquad L' = L_0 + L'_1 + L'_2; \quad . \quad (43b)$$

where R'_1 depends on the wire, R'_2 on the return; L'_1 on the wire, L'_2 on the return, and L_0 on the intermediate insulator. The forms of R'_1 and L'_1 have been given by Lord Rayleigh. They are, if $g^2 = \mu_1 n/R_1$, where R_1 = steady flow resistance of the wire per unit length,

$$\left.\begin{aligned} R'_1 &= R_1\left(1 + \frac{g}{12} - \frac{g^2}{12.15} + \frac{11g^3}{12.28.80} - \ldots\right) \\ L'_1 &= \tfrac{1}{2}\mu_1\left(1 - \frac{g}{24} + \frac{13g^2}{12^2.30} - \frac{73g^3}{12^2.28.80} + \ldots\right) \end{aligned}\right\} \quad . \quad (44b)$$

to the last of which I have added an additional term. The getting of the forms of R'_2 and L'_2, depending upon the return, is less easy, though only a question of long division. I shall give the formulæ later. At present I give their ultimate forms at very high speeds. Let ρ = resistivity, and q = frequency $= n/2\pi$, then

$$R'_1 = \frac{(\mu_1\rho_1 q)^{\frac{1}{2}}}{a_1} \qquad L'_1 = R'_1/n \quad . \quad . \quad (45b)$$

These are also Lord Rayleigh's. For the return we have

$$R'_2 = \frac{(\mu_3\rho_3 q)^{\frac{1}{2}}}{a_2}, \qquad L'_2 = R'_2/n. \quad . \quad . \quad (46b)$$

I express R'_1 and R'_2 in terms of the resistivity rather than the resistance of the wire and return because their resistances have really nothing to do with it, as we see in especial from the R'_2 formula. The R'_2 of the tube depends upon its inner radius only, no matter how thick it may be, that is to say upon extent of conducting surface, varying inversely as the area, which is $2\pi a_2$ per unit length. The proof of (46*b*) will follow.

Now, as regards the meanings. Let us call the ratio of the impressed force to the current in a line when electrostatic induction is ignorable the Impedance of the line, from the verb impede. It seems as good a term as Resistance, from resist.

Digitized by Google

(Put the accent on the middle e in impedance). When the flow is steady, the impedance is wholly conditioned by the dissipation of energy, and is then simply the resistance Rl of the line. This is also sensibly the case when the frequency is very low; but with greater frequency inertia becomes sensible. Then $(R^2+L^2n^2)^{\frac{1}{2}}l$ is the impedance. Here R and L are, in the ordinary sense, the resistance and inductance of unit length of lines including wire and return. When, further, differences of current density are sensible, the impedance is $(R'^2+L'^2n^2)^{\frac{1}{2}}l$. This is greater or less than the former, according to the frequency, becoming ultimately less, especially if the wire is of iron, owing to the then large reduction in the value of L′ as compared with L.

Now, when we further take electrostatic induction into account we shall have the above equations (34*b*) and (35*b*), in which R′ and L′ are the same as if there were no static charge. The proof of this I must also postpone. It is the only thing to be proved to make the above quite complete, excepting (46*b*), which is a mere matter of detail. The proof arises out of the short sketch I gave in section XXVII. of the general electrostatic investigation, used there for illustration.

The impedance is made variable; it is no longer the same all along the line, simply because the current amplitude decreases from the place of impressed force, where it is greatest, to the far end of the line, where it is least. The question arises whether we shall confine impedance according to the above definition to the place of impressed force, or extend its meaning. If we confine the use, a new word must be invented. I therefore, at least temporarily, extend the meaning to signify the ratio of V_0 to C_0 anywhere.

It is very convenient to express impedance in ohms, whatever may be its ultimate structure. Thus the greatest impedance of a line is what its resistance would have to be in order that in steady flow the current should equal that arriving at the far end under the given circumstances. It will usually be far greater than the resistance. But there is this remarkable thing about the joint action of forces of inertia and elasticity. The impedance may be far less than in the electromagnetic theory. That is, V_0/C_0 according to (41*b*) may be far less than $(R'^2+L'^2n^2)^{\frac{1}{2}}l$. This is clearly of great importance in connection with the future of long distance telegraphy and telephony.

(In passing I will give an illustration of reduction of impedance produced by inertia. Let an oscillatory current be kept up in a submarine cable and in the receiving coils. Insert an iron core in them. The result is to *increase* the amplitude of the current waves. More fully, increasing the inductance of the coil continuously from zero, whilst keeping its resistance constant, increases the amplitude up to a certain point, after which it decreases. The theory will follow.)

To get the submarine cable formulæ, ignoring inertia, take $L'=0$ and $R'=R$. To get the more correct formulæ, not allowing for variations of current density, but including inertia, take $L'=L$ the steady flow inductance, and $R'=R$. To get the linear electromagnetic theory formulæ, take $S=0$, and $L'=L$, $R'=R$. Finally, using R′ and L′ but with $S=0$, we have the complete electromagnetic formulæ suitable for short lines. Thus $S=0$ in (41*b*) brings it to

$$C_0 = V_0 \div (R'^2+L'^2n^2)^{\frac{1}{2}}.$$

Equations (34*b*) to (36*b*) are true generally, that is, with R′ and L′ the proper functions of d/dt. The solution in the case of steady impressed will follow, including the interior state of the wire. Also the interior state in the oscillatory case.

A great deal may be dug out of (41*b*). In the remainder of this section, however, we may merely notice the form it takes at very high speeds, so high as to bring surface conduction into play, and show how much less the impedance is than according to the electromagnetic theory. Let n be so great as to make $R'/L'n$ small. Then we may also take $L'=L_0$. Then

$$P = R'/2vL_0, \qquad Q = n/v.$$

Also, if ϵ^{-Pl} is small, as it will be on pushing up the speed, we need only consider the first term under the radical sign in (41*b*), which becomes

$$C_0 = \frac{2V_0}{vL_0}\,\epsilon^{-R'l/2vL_0}$$

Take for R′ its ultimate form

$$R' = 2(\mu\rho q)^{\frac{1}{2}}/a,$$

got from (45*b*) and (46*b*), by supposing wire and sheath of the same material and $2/a = 1/a_1 + 1/a_2$.

Then the impedance is

$$V_0/C_0 = \tfrac{1}{2}vL_0 \times \text{exp.}\frac{l(\mu\rho q)^{\frac{1}{2}}}{vL_0 a}$$

where exp. is defined by $\epsilon^x = \text{exp. } x$, convenient when x is complex. Here L_0 is a numeric, and $v=30$ ohms (*i.e.*, when we reckon the impedance in ohms); $\rho=1600$ and $\mu=1$, if the conductors are copper; and $l=10^5 l_1$, if l_1 is the length of the line in kilom.; therefore

$$V_0/C_0 = 15L_0 \times \text{exp. } (4l_1 q^{\frac{1}{2}}/30^4 aL_0)$$

To see how it works out, take $L_0=1$, $a=1$cm, and $q=10^4$; then $V_0/C_0 = 15 \times \text{exp. } 4l_1/300$ ohms.

If the line is 100 kilom., Pl is made $1\frac{1}{3}$, which is too small for our approximate formula. If 1,000 kilom., it is made $13\frac{1}{3}$, which is rather large. $Pl=10$ is large. If it is 500 kilom. then

$$V_0/C_0 = 15 \times \text{exp. } 6\tfrac{2}{3} = 1{,}178 \text{ ohms.}$$

So the impedance is only 1,178 ohms at 500 kilom. distance at the enormous speed of 10,000 waves per second. It is of course much less at a lower speed, but the more complete formula will have to be used if it be much lower.

Now compare this real impedance with the resistance of the line, in steady state, its effective resistance according to the electro-magnetic theory, and the impedance according to the same. The resistance of the line we may take to be twice that of the wire, by choosing the return of a proper thickness, or

$$Rl = 2 \times 500 \times 10^5 \times 1600/\pi = 50 \text{ ohms say.}$$

L will be a little more than $1\frac{1}{2}$, say 1·6, therefore

$$Ln = \cdot 8 \times 2\pi \times 10^4 = 5060$$

so that the linear theory impedance is nearly 5,100 ohms.

But, owing to the high speed, we should use R′ and L′ instead of R and L; here take $L' = L_0 + R'/n$ and

$$R'l = 400 \text{ ohms.}$$

This large increase of resistance is more than counterbalanced by the reduction of inductance, so that the impedance is brought down from the above 5,100 to about 3,500 ohms, the electromagnetic theory impedance; and this is about three times the real impedance at its greatest, viz., at the distant end of the line.

It is further to be noted that the wire and return need not be solid, as we see from the value of R′ compared with R. What is needed at very high speeds is two conducting sheets of small thickness, of the highest conductivity and lowest inductivity; *i.e.*, of copper.

(To be continued.)

NEW ELECTRIC DETONATORS FOR FIRING MINES.

The means hitherto adopted for firing mines present inconveniences more or less serious. Formerly a small funnel or tube filled with powder used to be placed at the mouth of the bore, furnished with a bit of tinder which was set on fire; but too often, some powder being scattered about the mouth of the bore or on the tinder, the mine exploded before the workman had time to escape, occasioning frequent and terrible accidents. Besides, there was always the trouble of making the tubes themselves. Later there came into use the Bickford fuse, which marked a great advance, and was received with a good deal of favour because of the simplicity of its application. Unfortunately it is not free from imperfection. For instance, at the moment of its ignition, which is occasionally difficult to effect, a jet of flame and sparks from 3 to 4in. long is observed; hence the serious danger to mines where there is fire-damp. Moreover, this fuse emits a very disagreeable thick black smoke; but its greatest defect lies in the fact that it is sometimes cut during the violent operation of tamping, which must be done with a good

Digitized by Google

deal of force to be efficacious and to avoid blowing out. The fuse may be accidentally cut and rendered useless or ignited prematurely. It has other defects, and is also somewhat costly.

The purely electrical system is superior to any of the preceding methods, on account of the certainty of its results and the advantage which it affords of causing several shots to be fired simultaneously. But it has the drawback of being expensive by reason of the high price of the detonators. Besides, the wire of the latter may also be cut during the process of tamping, which is at least not without danger, since it is effected on detonators containing a combustible composition. MM. Scola and Ruggieri have invented a system of firing mines which obviates the foregoing objections. The Ruggieri fuse, which is the name given to it, is composed of a small tube of pasteboard, A, of conical shape in the exterior, and enclosing a fuse or filament, B, a bit of spun cotton coated with a powder paste. The large end of the tube is stopped by an electric detonator (a mixture of chlorate of potash, saltpetre, sulphate of ammonia, and finely-granulated carbon) of peculiar construction, C, solidly fixed, the ends of which, D D, remain outside. This tube is placed in the cavity left by the boring instrument, being solidly secured after the manner of a spigot in a cask on account of its conical form. The wires D D are attached to a cable with two conductors communicating with an induction machine—from which the current is obtained—the detonator is ignited and fires the fuse contained in the tube. The action is therefore absolute, there being no time lost in uncertainty. In fact, if the fuse,

Fig. 1.—The Ruggieri Fuse or Projectile Igniter.

Fig. 2.—Bore of a Mine charged with Powder, and provided with a Ruggieri Fuse.

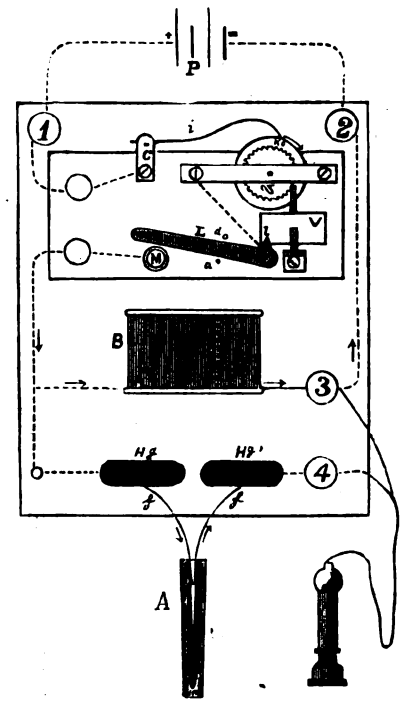
Fig.—Bore of a Mine charged with a Dynamite Cartridge, with Cap, and provided with a Ruggieri Fuse.

although burnt, does not reach the bottom of the bore, as it is composed of an insignificant quantity of material (two or three grains), it is consumed on the way, and leaves only an ash, quite cold in five or six seconds at the most. There is therefore no danger in approaching the shot hole in case of failure, which, however, is not likely to occur, as the detonators are of extreme sensibility. They are during manufacture tested with care by apparatus invented by M. Ducretet, for prompt and easy examination of the detonators by tension, an examination not possible hitherto. To sum up, the Ruggieri fuses obviate the inconvenience of preceding systems. They especially assure to the miners absolute security in consequence of the distance between the charge and the igniter. They do away with flame, so dangerous in mines where there is fire-damp, as well as obviate the loss of time, smoke on account of the minimum of combustible material, and the danger arising from explosive compounds, while their compactness permits of their being easily moved about. Finally, a greater or lesser number may be fired simultaneously according to the strength of the induction machine. In mines charged with dynamite, where there is no need for tamping, the process undergoes a slight modification. In the dynamite cap B A are placed a few pieces of wick or filament, C, leaving one or two centimetres projecting; the top of the copper mounting is flattened, and then the cap is placed in the dynamite cartridge D, which is pushed to the bottom of the hole. There is placed at the mouth of the latter a large stopper of cork or of wood, pierced so that there is an orifice to permit of the admission of the Ruggieri fuse. The wires are attached and the shot is fired. When the fuse ignites it shoots right to the bottom of the bore on to the filament of the cap, which causes the detonation of the dynamite. The stoppers may be used over and over again. MM. Scola and Ruggieri, in order to complete their system of firing, have devised a magneto-electric machine, which by a peculiar arrangement forces a spark of an extra-current to be produced in an enclosed space without communicating with the surrounding air. This machine can, therefore, be worked in an atmosphere impregnated with fire-damp, without causing any explosion through the spark from the machine. This powerful apparatus is constructed with care by MM. E. Ducretet and Co.

APPARATUS FOR TESTING ELECTRIC DETONATORS.

In the manufacture of electric detonators with an interrupted wire designed for firing mines it is necessary, by some rapid process, to be assured before using them of the quality of the



detonators, so as to discard all those the effect of which would be uncertain. To attain this end the detonators must be arranged in such a manner that the spark from the extra current of the electrical apparatus may flash out with certainty in the middle of the combustible material. It is therefore necessary to be sure, first, that the two copper wires are not in metallic contact, which would happen where the protecting covering was taken off; and, secondly, that they are yet sufficiently near so that the sparks may flash out between them. These apparently very delicate conditions may nevertheless be ascertained in the most perfect and rapid manner by means of an apparatus designed by M. E. Ducretet. This apparatus is composed of a battery, P, with three Leclanché cells, from which the current goes through an interrupter with

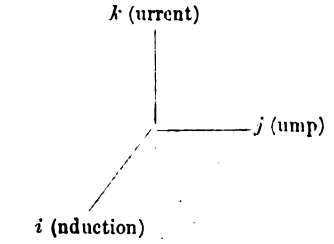
Digitized by Google

a clock-like movement, R, and afterwards a coil of fine wire, B, and ends in two cups of mercury H*g*, H'*g*. Finally, a telephone, T, is placed in shunt circuit, as shown. When the interrupter is put in motion, and one of the wires of the detonator is dipped in each of the cups, and contact made between the detonator and mercury cups, a rattling noise is heard when there is metallic contact between the copper wires. If, on the other hand, the two wires or the uncharged detonator are absolutely insulated, the telephone is mute; and, lastly, if the detonator is of good quality, a feeble crackling is perceived, resulting from the passage of the electric current through the combustible matter. In the last case the detonator may be considered to be of good quality, and its detonation may be safely relied upon. It is thus easy with this apparatus to examine in a very short time a number of detonators, the resistance of which is above a million ohms, and to ascertain their quality with absolute certainty; detonators tested previously by exact methods with the galvanometer may be used as types to work upon with the telephone. In this connection it may not be without interest to remark that the tests of the platinum wire detonators by means of the galvanometer, such as are employed at the military and naval departments, do not indicate whether the detonator is charged; it might not be so. M. Ducretet's apparatus may in such case be successfully applied, thus effecting a double test, which is of great importance; in other words, in the case of a detonator with an interrupted wire, no sound is heard through the telephone when the detonator is not charged. We have to add that the same machine is adapted for quickly ascertaining circuits of great resistance as well as to verify their insulation.

AMPERE'S RULE.

Again Mr. George M. Minchin, of the R.I.E. College, Cooper's Hill, sends the following ingenious device to our contemporary *Nature* on the subject of Ampère's rule:—"The following version of Ampère's rule is one which I communicated some time ago to a few friends, but it did not appear to me to be expressed in language sufficiently grave to justify its publication. Still, as the rule is a simple and useful one, your readers, in general, may be disposed to overlook its levity.

Draw the three well known Hamiltonian vectors *i j k*. After *i* put (nduction), after *j* put (ump), and after *k* put (urrent), then the figure explains the action of magnetic induction on an electric current. The figure, in fact, asserts that *i* (nduction) in *i* makes *k* (urrent) in *k* to *j* (ump) along *j*.



Of course the same figure gives the direction (according to the law of Lenz) of the current generated by a motion (*i.e.*, a jump) of a conductor in a given direction in a magnetic field in which the direction of the induction is given."

OXIDATION OF IRON BY ELECTRICITY.

The following is the substance of a paper by M. A. de Meritens read before the International Society of Electricians at their meeting on the 7th inst. M. de Meritens began his subject by referring to the misuse of scientific terms and to the discovery of electroplating, and proceeded to show that an ordinary piece of soft iron exposed to the atmosphere easily oxidises in a few days, that pure iron prepared in a laboratory resembles silver in lustre, and takes on a brilliant polish extremely durable, is more elastic than ordinary iron, and possesses a specific gravity of 7·80. He then said: This metal is less oxidisable than ordinary iron; but notwithstanding this circumstance it is attacked in a moist atmosphere, and it is easily dissolved in dilute acid. However much care may be bestowed on its manufacture its condition is not one of absolute purity. He then showed a specimen obtained by electrolysis. Its specific gravity is 8·14. It is almost unoxidisable. Acids at the ordinary temperature exercise hardly any influence upon it. If it is heated to a red heat, and then rapidly cooled, its malleability will be found not to have diminished, while its hardness has not increased. When it is melted the hydrogen which it gives off has not that peculiar odour which is observed in hydrogen exhaled from a solution of ordinary iron. The three metals mentioned differ little in their composition. The difference in the two last are infinitesimal and scarcely appreciable on analysis. And yet the last has almost nothing in common with the other two. It possesses properties and affinities peculiar to itself. Zinc may be placed in the same category. The specimens of galvanised iron which are before you, and which you may examine presently, were kindly given to the speaker in 1876 by M. Jacobi from his laboratory at St. Petersburg. Since then he had never seen better deposits of iron obtained by electrolysis. This was not surprising, however, seeing that it came from the birthplace of electro-deposition. By means of electricity an almost perfect metal was obtained, and what we required was to preserve that metal when in contact with the air. Before touching on the very brief details of the operation it might be useful to glance at the actual industry, and the means of preservation which it employed. The author said that the processes in use for preserving sporting and military gunbarrels from oxidisation by the action of the atmosphere were innumerable.

He then described various of the means adopted for the bronzing of guns, pointing out that the work was not without danger, besides being neither expeditious nor entirely satisfactory. The aim in each case was really to obtain a magnetic oxide Fe^3O^4.

The electric current, he went on to say, must solve the problem, as it had solved that of metallic deposition. The operation was simple and expeditious. The bath was filled with ordinary water, or, better still, with distilled water, heated to a temperature of from 70 to 80 degrees centigrade. The polished piece to be oxidised formed the anode, while a plate of copper, or carbon, or iron, might be used as the cathode. In the speaker's own work he used the sides of the iron vessel as a cathode. The current must have only the E.M.F. necessary to decompose water after having overcome the resistance of the circuit and of the bath.

The operation must be conducted the same way as in electrolysis. Too strong a current produced a non-adherent oxide. There was besides the usual inconvenience of keeping the polished pieces clean in the process. After a few minutes in the bath the polished pieces became black. Magnetic oxide was immediately formed under the influence of the current. After an hour or two's action the layer of oxide Fe^3O^4 was sufficiently solid to resist the action of the scratch brush. It easily took the brilliant polish of the numerous specimens which he exhibited. It had penetrated the pores of the metal. The penetration was even sufficiently deep to give rise to the following effect:—A gun, such as those they now saw, had been oxidised to a brilliant black. He completely removed the magnetic layer by means of emery. The gun became again white. It was dipped afresh into the bath and took on the black again almost instantaneously on the passage of the current. Let them take an old piece of iron exposed to wet for years—it would be covered with a layer of sesqui-oxide of several millimetres in thickness—then place it in a bath of hot water and pass the current. Fe^2O^3 would be entirely transformed to the whole of its thickness into Fe^3O^4. The exterior layer would be non-adhesive. The under layers would be as hard as the iron itself.

During the whole of the first part of his studies on this very interesting subject he had treated only pieces of steel. Sporting or military guns, scabbards of swords, bayonet sheaths were of steel. When he turned his attention to objects made of soft iron, either malleable or cast, an unforeseen difficulty arose. The magnetic oxide obtained with great difficulty had no adhesiveness. On the slightest rubbing it disappeared. He varied the temperature of the bath, and even modified the E.M.F., without success. The hardest steel and most strongly tempered was the metal most easily covered under the action of the current with magnetic oxide, soft iron being the most difficult to treat. It was necessary to find the means to bring it into a molecular condition analogous to those of steel to obtain good results. By the advice of a learned chemist he placed pieces of soft iron in contact with the negative pole of his apparatus after they had been subjected to the action of the current from the positive pole. Taken again to the anode the pieces of soft iron took the magnetic oxide with greater ease and very much greater firmness, but the result was not yet perfect.

He then changed the ordinary water for distilled water, and the work was done to his entire satisfaction. The best of the procesnt in use at the present time, of which he spoke at the commencemsses required not less than from eight to ten days before the operation was complete. The time by the employment of electricity was reduced to as many hours.

THE NEW FRENCH ATLANTIC CABLE SCHEME.

By a very narrow majority the French Chamber of Deputies has refused urgency for the discussion of a project for laying a new Atlantic cable at the French Government's risk and subsidised by French public money. For the moment the subject is in abeyance; but we may rest assured that the audacity which sprung this extraordinary proposition upon the Chamber will not be cowed by any temporary rebuff, and that, urgent or not urgent, the subject will soon again come on for serious discussion. It is almost too much to hope that anything an English journal can say in opposition to the scheme will influence the decision one way or the other; but none the less is it our duty not to remain silent, especially as English interests are gravely involved in the final decision of the French Deputies. We do not apprehend that English investors will be so foolish as to risk their money in assisting French capitalists to float this new venture; and we are glad to remember that there is at least one Atlantic cable largely owned by Frenchmen who will do their utmost to prevent a wanton and suicidal addition to the competitors now contending for Atlantic telegraph traffic. The English Companies will of course resist it with all their might; but their resistance cannot be very formidable, and in one sense it might even conduce to provoke that national jealousy on which the French promoters will rely in making their appeal for subscribed capital. Nevertheless, as the proposal to lay a fresh Atlantic cable is from every point of view objectionable we ought not to abstain from saying so for fear of being misunderstood. It happens that English interests and French interests are in this relation identical. The idea of a new cable between Europe and the United States is bad, but is neither better nor worse for being a French idea.

So far as can be gathered from the discussion of it in the French Chamber of Deputies, the scheme appears to be to lay a cable from France to the Antilles, thence through French Guiana, and northwards to the United States. Why this devious and hazardous route has been chosen becomes plain when we learn that it is intended to afford a more rapid and independent means of communication for France with her colonies, and "a greater scope for the development of French colonial trade." On the strength of conferring this boon upon the commerce of the French Republic a considerable subsidy, amounting to probably a million francs per annum, for the next twenty-five years is asked for, with a virtual guarantee of the capital embarked in the undertaking. To these conditions the Government appears to have complacently assented, although nothing is publicly disclosed as to the character or personality of the promoters. Whoever they may be they evidently are well acquainted with the one sure way of tapping the national pocket. We may smile at the talk about French colonial development; but it flatters French vanity, and probably by no other method, or for no other route, would money be obtained in France or elsewhere for submerging another Atlantic cable at this moment. It is often asserted that the French Government has fallen into the hands of a band of greedy speculators; and when one sees a scheme of this character solemnly submitted to the Chamber by a Government official the reproach would seem to have some justification. Nobody could legitimately profit by such a cable except the promoters and manufacturers, who are at present unknown; and that any Government should deliberately take it up gives rise to the suspicion that profits of an illegitimate kind are somewhere in the background. M. de la Ferriere gave expression to some misgivings of this kind on the occasion of the motion for urgency; and thanks to his vigorous onslaught upon it the proposition has been adjourned for a while.

Foremost among the pleas put forward in defence of the scheme by the Minister of Posts and Telegraphs was a singular complaint as to the present unsatisfactory state of communication between France and her colonies. This can have reference only to her West Indian colonies; and as communication with them was never more rapid than it is at present, or ever nearly so cheap, it is difficult to understand the argument from either a political or business point of view. The fact that the existing Atlantic cables have doubled, and more than doubled, their traffic within the last three months is proof not only of their capacity for carrying a vast deal more work than has fallen to them in ordinary times, but of their ability to dispose of it expeditiously. Cheap rates would not compensate for slow transmission; and we have reason to believe that the average speed has by no means diminished during the pressure of severe competition. We could at least respect a desire on the part of the French Government to secure a military connection with her distant colonies; but no such motive is put forward, and indeed in this particular case military considerations are almost out of the question, even if they could be served by a cable whose existence, as we have recently shown, would cease directly the necessity for it arose. The development of colonial trade is not dependent on communication by any particular route, and it is hard to see how French commerce would gain by telegrams being sent *vid* the Antilles rather than by the Northern States. The bulk of the cables take the last-named route, and the service of a fresh cable in a different direction would at best be precarious and partial.

The mystery of this French project is greatly enhanced by the circumstance that the existing battle of the rates between the European and American continents has arisen through

Digitized by Google

there being too many cables already. For some years past they have been earning small profits, and with the addition last year of two more cables the whole of them ceased to earn any. As a matter of fact there is not enough business to support more than a limited and easily computed number of Atlantic cables, except perhaps at rates which would leave them idle for many hours every day. To add another to the superabundant competitors is therefore an outrage on all business principles, and a gross wrong to the owners of cables already laid. The French Government and the French promoters of this projected new cable to the Antilles cannot be unaware of these notorious facts, and it is pretty evident that commercial considerations of the ordinary kind have not entered into their calculations. It was the easiest thing in the world to prove that a new cable could not pay at the prevailing rates of 6d. per word or thereabouts; consequently a State subsidy would be necessary, and a State guarantee. No better time could have been chosen for the application, but it still remains an enigma how any honest Government could have condescended to listen to it.

CORRESPONDENCE.

NERVOUS FORCE AND ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the letter of Mr. Aldred Williams in your last number I am able to say that I have confirmed the results of my previous experiments by holding platinum wire in my own hands, and also by getting the left-handed man to hold the wires in his hands.

As to the sensitiveness of the galvanometer, a current of 13,353 millionths of an ampere will cause a deflection of one scale division. I suppose the average deflection I have obtained would be about 4,000 scale divisions.

It is very important in these experiments to make good contact, because with thin magnesium wire the deflection is uncertain, the needle vibrating indiscriminately; also with very soft lead wire the current seemed to start from my left hand; whereas, when I used hard German silver, the deflections were unquestionably as I described them in my letter to your journal on June 25th. With reference to the experiments with lead wire, I will not attempt to explain the curious results; it strikes me that some very complicated phenomena must have taken place, and if my observations are of any value I hope some explanatory or suggestive remarks may be forthcoming.—Yours, &c., ARTHUR WILLEY.

45, Gladstone-avenue, Noel Park, July 21, 1886.

ON THE SIZE OF CONDUCTORS FOR INCANDESCENT LIGHTING WHEN LAMPS ARE IN MULTIPLE ARC.

BY H. WARD LEONARD.

1st. Size as determined by a required loss of electromotive force in the conductor.

In the various electrical text books and journals there is great dearth of practical information upon this subject. In the principal companies engaged in installing incandescent lamps, most of the *employés* use formulæ for the determination of the circular millage of a wire which depends directly upon the resistance of the lamp and upon some percentage of loss of the total available electromotive force, and which involve the use of a "table of constants," a different constant being required for each candle-power of lamps of the same electromotive force and having the same economy, and also for each variation in electromotive force in lamps of one candle-power.

The writer, after deriving and using quite a number of different formulæ which were steps towards increased simplicity and accuracy, last year derived the formula given below, and its use by himself and others associated with him has been so satisfactory that he has been led to hope that it may be of assistance to some who are at present inconvenienced by the necessity of a "table of constants" which are worthless in case of a variation of candle-power or economy of the lamps they apply to.

Let E = E.M.F. required to bring lamps to nominal candle power.
" C = the current required by lamps in amperes.
" C P = the aggregate candle-power of the lamps.
" C H P = the economy of lamps expressed in candles per electrical horse-power.
" V = the loss of E.M.F. in the conductor both ways, expressed in volts.
" D = the distance to the lamps expressed in feet.
" M = the number of circular millage of the wire.
" R = the resistance of the wire both ways.

Since 1 watt = 44·24ft.-lb. per minute, we have

E + C + 44·24 = the ft. lb. per minute absorbed by the lamps.

Now evidently $$\frac{E \times C \times 44{\cdot}24}{33000} = \frac{C\,P}{C\,H\,P}$$

$$\therefore \quad C = \frac{33000 \times C\,P}{E \times 44{\cdot}24 \times C\,H\,P} \quad . \quad . \quad . \quad . \quad . \quad . \quad 1.$$

Now, the resistance of 1ft. circular mill of copper of 96 per cent. conductivity = 10·725 ohms.

$$\therefore \quad R = \frac{10{\cdot}725 \times 2\,D}{M}$$

By Ohm's law $$C = \frac{V}{R}$$

$$\therefore \quad C = \frac{M\,V}{10{\cdot}725 \times 2\,D} \quad . \quad . \quad . \quad . \quad . \quad 2.$$

Now by (1) and (2) we have

$$\frac{M\,V}{10{\cdot}725 \times 2\,D} = \frac{33000 \times C\,P}{E \times 44{\cdot}24 \times C\,H\,P}$$

Whence $$\mathbf{M = \frac{D \times C\,P}{V \times E \times C\,H\,P} \times 16000}$$

By the substitution of the economy in candles per horse-power, we have a formula of extreme simplicity with but one constant for lamps of one economy, no matter what the variations of candle-power and the electromotive force required may be.

For example, in the case of Edison lamps, which have an ecomony of 160 candles to the electrical horse-power, the formula becomes

$$M = \frac{C\,P \times D \times 100}{V \times E}$$

And it will be noticed that in the case of lamps of 100 volts, which are largely used in the Edison system, the constant vanishes and the formula becomes

$$M = \frac{C\,P \times D}{V}$$

which for simplicity it would be difficult to excel.

From the results of the Franklin Institute test, the constants for the various lamps are given in the table below; as the candle-power of the various lamps was not the same, the mean spherical candle-power is also given.

Name.	Description	Sp. Candles per El. H.-P.	Mean Sp. Candles.	K.	Relative Size of C'nd'ctor Required

2nd. On the size of conductors as determined by the heating due to the current.

D = diameter of wire in mils.
M = No. of circular millage of wire area.
C = current in amperes.
R = resistance of unit length of wire.

K', K'', and K''' = constants.

The surface of wire of unit length = π D.
Heat radiated varies directly as π D.
Heat generated varies as C^2 R.
Now R varies inversely as M.

$\therefore$ heat generated varies as $\frac{C^2}{M}$

or $$= \frac{C^2}{M} \times K',$$

where K' is some constant.

Similarly, heat radiated $= K''\pi D$, and since $D = \sqrt{M}$, we have heat radiated $= K''' \sqrt{M}$.

Now, since when the temperature of the wire is constant, the heat generated will equal the heat radiated, we have

$$\frac{C^2 K'}{M} = \sqrt{M} \times K'''$$

$$\therefore \quad M^3 = C^4 \times K$$

$$\therefore \quad M = C^{4/3} \times K$$

and $$C = \frac{M^{3/4}}{K^{3/4}}$$

In practice the only wires of a system of conductors for incandescent lighting which we need expect excessive heating in, are the so-called "omnibus" wires, which carry the total current, and possibly the feeders, which also carry heavy currents.

TABLE A.

Gauge number B.W.G.	Sectional area in circ. mils.	Safe current in amperes.	Circ. mils. per ampere.

16	4225	17	255
17	3364	14	241
18	2401	11	221

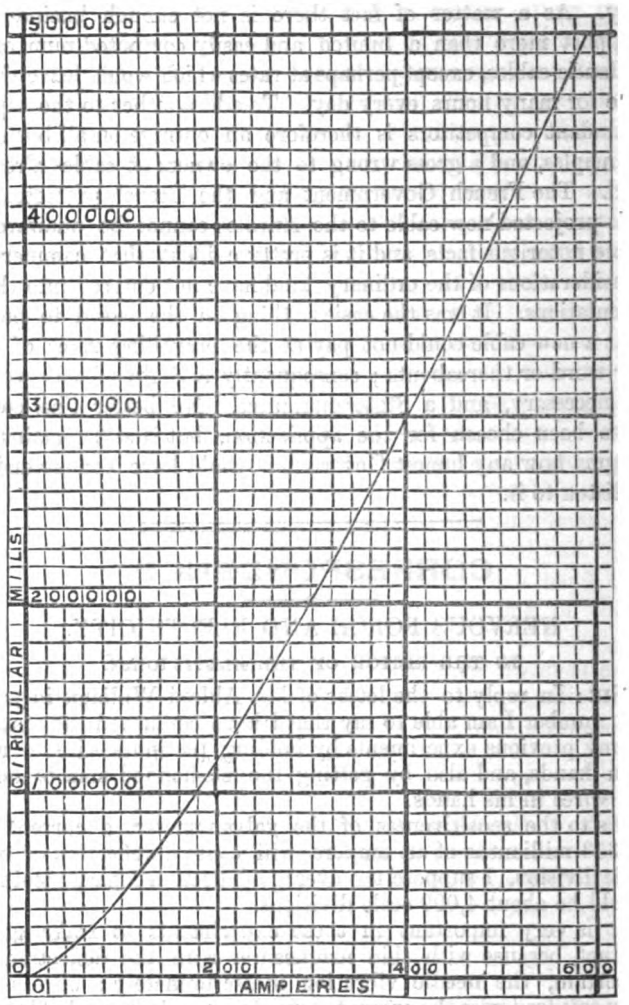
The results of some experiments on bright bare copper wire gave the value 100 for K in the above formula when the temperature of the wire was raised 81 deg. F. or 45 deg. C. That is, for such a rise of temperature as that mentioned the formula becomes

$$M = C^{4/3} \times 100$$

and $$C = M^{3/4} \times \cdot 0316$$

The above formula is applicable to cases when bare or insulated (which latter will be at somewhat lower temperature) wire is to be used and is to have free access to air

Table A gives the data derived from the use of this formula as regards the size of wire for various currents, and a curve plotted from the table is shown below.



Curve plotted from Table A.

In the case of armatures 60° C. is about the maximum safe rise of temperature admissible.

For armatures of the Siemens and similar types, the constant for 60° C. rise is 140. That is, the formula becomes

$$M = C^{4/3} \times 140$$

and $$C = M^{3/4} \times \cdot 02457.$$

Chicago, May 16, 1886.

MAGNETIC RESEARCHES.

BY PROF. G. WIEDEMANN.

(*Continued from page 201.*)

It is also to be observed that the permanent torsions into which the bar, left to itself, slowly passes from the temporary torsions 0° and 210° do not at all agree with the torsions at which it shows the maximum of temporary magnetism; these last lie further away from the extreme torsions than the permanent torsions do.

If we consider the changes in temporary magnetism in the first torsion, we observe in every case an increase and then a decrease, evidently because the molecular magnets, directed more or less axially by the magnetising force, obey at first that force still further in consequence of vibration, and are then carried from their axial position into more oblique positions. This is confirmed by the fact that with very strong temporary magnetism the first rise through vibration is less than with less powerful magnetisation, since in the first case the molecules are already more nearly in the axial position.

Digitized by Google

With permanent longitudinal magnetisation the directing force of the external magnetising power is absent; the molecules, disregarding mutual action, are affected only by the displacements produced by torsion, which consequently manifest themselves more distinctly than in the previous experiments. The moment at the limiting-points is different, and thus also the position of the molecules. But again, the most rapid rotation of the molecules at the beginning of each deformation is seen within the given limits.

A similar behaviour is observed in the case of temporary transverse magnetisation, in which the magnetic directing-force which acts upon the molecules is one-sided; and so the moments at the limiting-points cannot be equal. Nevertheless, the rotations of the molecules with rising and falling torsion here also preserve the above-mentioned character.

V. In exact analogy with the mechanical and magnetic behaviour described in Section 4, it may be shown that if a wire which has been subjected to a temporary deformation (as a special case, this deformation may be zero) then suffers another deformation, the molecules again retain the position corresponding to the first deformation up to a certain degree.

In order to make these experiments, a wire was temporarily twisted by forces 0, a, b, gradually increasing, and its temporary torsion measured, as also with decreasing forces b, a, 0. For this purpose the same apparatus was used as in my former experiments. A flat weight $\gamma\gamma_1$ provided with a hook was attached to the thread $o\,q$ which acts upon the torsion circle; to this a second weight $\beta\beta_1$, with a hole through the centre, was attached by lateral threads $\alpha\beta\gamma$, $\alpha_1\beta_1\gamma_1$. These threads were connected to a horizontal wire $\delta\epsilon$, which was soldered to the frame of a pulley η suspended by the thread $\zeta\theta$. The end θ of this thread was attached to a fixed hook, the end $\zeta\theta$ passed over a fixed pulley to the windlass z. If by turning ζ the pulley η was gradually lowered, the weight $\gamma\gamma_1$ at first acted upon the torsion circle until the weight $\beta\beta_1$ reached the other, when both together acted in twisting the wire. The horizontal wires soldered to the weights rested against fixed vertical wires, and so prevented the turning of the weights with the threads carrying them. By winding up the pulley η, the torsion corresponding to the weights $\beta\beta_1+\gamma\gamma_1$ and that corresponding to the weight $\gamma\gamma_1$ alone could be determined. The weights were always raised and lowered very slowly, so that they produced their effect without any jar. The reading each time was not taken until, after putting on the weights, the temporary torsion did not perceptibly change any more. The weight $\gamma\gamma_1$ (1) weighed 61·8 gr, $\beta\beta_1+\gamma\gamma_1$ (1)+(2) 125·9 gr.

As before, the torsions were read off by means of a telescope in a mirror, which was attached to the lower clamp of the wire subjected to torsion, and in which the image of a semi-circular scale, placed round the wire as axis with a radius of 1 metre, was reflected. The following tables contain some of the results obtained. The first column gives under G the weights used to produce the torsion, the following columns give the corresponding torsion successively obtained. The experiments were continued until the same torsion was obtained upon renewed action of the weights.

I. Brass wire, 2 millim. thick and 51·8 millim. long, stretched before loading by a weight of 8350 gr., and annealed under a load of 8000 gr.

G.	I.	II.	III.	IV.	V.	VI.
0	0	223·5	242·5	255·5	264·2	267·3
(1)	684·0	904·5	924·5	937·0	943·0	947·0
(1)+(2)	1691·7	1705·0	1706·7	1713 5	1714·0	1714·5
(1)	973·0	989·5	693·5	990·5	1000·5	1001·5

G.	VII.	VIII.	IX.	X.	XI.
0	269·5	273 0	273·0	275·0	281·0
(1)	949	950·5	952 0	953·5	957·2
(1)+(2)	1714·5	1714 5	1718·5	1719·5	1721·5
(1)	1002·5	1002·5	1005 0	1004·3	1000·5

After ten repetitions of the increase and decrease the deflections obtained were :—

G.	XXI.	XXII.
0	.....	287·5
(1)	.....	965·7
(1)+(2)	1717 8	.....
(1)	1000·5	.....

A similar wire annealed while loaded with the stretching weights gave the following values :—

Torsion.

G.	I.	II.	III.	IV.	V.
0	0	232·5	250·2	262 0	266·5
(1)	701·3	928·5	947·5	962·3	—
(1)+(2)	1711·5	1723·7	1736·5	1733 7	—
(1)	982·5	990·5	999·5	999 0	—

After action of the weights, repeated ten, twenty, and thirty times, the deflections were :—

G.	XXV.	XXXV.	XXXVI.
0	274·0	276·0	276·0
(1)	976·5	975·0	976·0
(1)+(2)	1731·5	1729·5	1729·5
(1)	996·7	999·0	997 0
0	274·5	276·0	276·0

Next the wire was caused to vibrate strongly so as to emit a musical note by striking it with a flat board whilst loaded with the weight (1) during the increase as well as during the decrease of the weights, and also whilst loaded with the weights (1)+(2). The values thus obtained are given within brackets, against the values obtained before the vibration :—

G.	XXXVII.	XXXVIII.	XXXIX.	XL.
0	276·0	292·5	391·5	419·5
(1)	977·0 (984·5)	988·7	1092 (1095·5)	1121·5
(1)+(2)	1738	1746·0 (1861·5)	1853·5 (1890·5*)	1880·5
(1)	1000·5 (1007·5)	1120·5	1150·5	1145·5
0	292·5	391·5	419·5	420·5

* Made to vibrate powerfully and for a long time.

It follows from these experiments that the temporary torsion of the wires, produced by the smaller weight after the action of the greater weight, with a decreasing load, is in every case greater than that produced by the action of the same weight with increasing load, and before the action of the greater weight. The behaviour is observed not only during the accommodation of the wire, but also after it has attained a permanent condition, when a repetition of the cycle of experiments gives the same results. It also is not altered by strong vibration of the wire.

(*To be continued.*)

SELECTED CORRESPONDENCE.

[The following correspondence has appeared in *The Times* on the question of Judges and Patents. It arises out of the late telephone trial. The first letter given called forth a leader in *The Times* upon the subject.—Ed. *E.*]

The very wide experience of Mr. Imray, past President of the Institute of Patent Agents, as a professional expert in patent litigation gives unusual value to the views which he has put forth in the reply which he gave in your columns of July 7. I have, indeed, in one or two cases been subpœnaed as a scientific witness; had I not been, I should probably not have seen so much of the evil practice to which I have drawn attention, and which has of late been the subject of much unpleasant comment in the technical journals. But my experience is nothing as compared with that

Digitized by Google

of Mr. Imray; hence I hail as of peculiar value his contribution to the question of the judicial warping of patents.

Mr. Imray, in his capacity as a professional expert, now lays down the whole duty of the Judge in a manner which I believe is quite borne out by the actual recent practice of the Courts. He is referring specifically to a certain patent taken out by the American electrician Edison, and he says: "In such a case Judges *who know their duty*"—the italics are mine—"do not tie down the invention to the precise details given by the inventor; they look for the principle on which the invention is based." That would, I take it, be entirely fair if the inventor had discovered, stated, and claimed the principle on which his invention is based. But, unfortunately for Mr. Imray and for the example in point, the inventor in this case has particularly and in terms thrown aside any claim to the general principle. The claiming clause of the Edison specification is preceded by an emphatic statement that the inventor observes in conclusion that he does not claim the general principle, which in fact was old and publicly known at the date of his patent. Mr. Imray's statement therefore amounts to this—that a Judge who knows his duty (the phrase is a useful one) will give the inventor that which the inventor has expressly disclaimed. Mr. Imray's statement clearly confirms my contention that there exists a judicial practice of patent warping—a practice which is essentially unjust. But Mr. Imray's letter is still more informing as to the part played by experts in misleading Judges. Though he is angry with me for saying that such things are done, he is so kind as to furnish me with a typical example. He declares that Edison's invention was not a mere improvement in constructive details or in combinations. Now there is only one claim in the Edison specification, and it reads thus:—"but I claim as my invention, in an instrument for transmitting electric impulses by sound, *the combination* with a diaphragm or tympan of electric tension regulators, &c." Mr. Edison, inventor, claims as his invention a combination; Mr. Imray, expert, declares that it did not consist in combinations. Which is right? Is this the kind of evidence that Judges are accustomed to get from experts? Will Mr. Imray swear in court that Edison's sole claim does not consist in a combination?

Lastly, Mr. Imray says that Edison's telephone patent is a "new invention" of a "fundamental" character, an "altogether novel departure," and that it is *in such a case* that Judges who know their duty do not tie down the invention to the precise details given by the inventor. It is not self-evident why a Judge should be so unjust as to give to a patentee a monopoly over more than his patent entitles him to, even if he were the discoverer of an absolutely new departure in invention. But, in this instance, Mr. Imray knows as well as I do that Edison's own specification states that the patent is for "improvements"—improvements on the telephones that had gone before; that the patentee was given by his employers a description of the earlier instruments as a basis on which to improve, and moreover that the "new invention" was of so very "fundamental" a character that it was of no practical use until after the subsequent invention by Hughes of the microphone. Yet Mr. Imray urges this "fundamental character" as the reason why Judges should not tie down the inventor to the precise thing that he has invented! In other words, let an eminent expert bamboozle the Judges into thinking that a mere improvement is a great and new invention; let him swear as an expert that a mere claim to a specific combination is a claim to a general principle; then the Judges "who know their duty," as laid down in the ethics of the Past President of the Institute of Patent Agents, will do it. I take Mr. Imray's letter as furnishing a singularly apt illustration of the way in which Judges "are misled by counsel and expert witnesses to such an extent that they quite misunderstand patent specifications, and consequently give unjust judgments." That is precisely what occurred in the recent case of the United Telephone Company *versus* Bassano, at least as regards those issues of Mr. Justice North's judgment which were not confirmed by the Court of Appeal, and also, if *The Times* report of the proceedings of the Court of Appeal be correct, in the stretching by Lord Justice Cotton of Edison's specification so as to include in it things that were invented a year afterwards by Hughes And there are various other recent cases—notably the gas engine decisions—in which a similar judicial warping of patents has occurred. SILVANUS P. THOMPSON.

City and Guilds of London Technical College,
Finsbury, July 12.

Except in response to a virtual challenge, I should not trespass on your valuable space, but the letter from Prof. Silvanus Thompson which you published on Saturday and your leading article on the question raised by him call for some reply, which I will endeavour to make a brief one.

In my former letter I said, or intended to say, that, in dealing with an invention of a fundamental character, Judges properly give a wider interpretation to patent claims than when they have to deal with mere improvements in the details of known inventions. When Watt made the steam engine a success by condensing steam that had done its work in a vessel separate from the cylinder in which fresh steam had to perform work, his patent was upheld, not for any particular form or construction of condenser, nor for any particular mode of condensing, but simply for the separation of the condensing vessel, whatever it might be, from the working cylinder. It was a new idea or a new principle, and it has been properly held that when there is such an idea embodied in an apparatus or process that can be copied or followed with advantage, a patent may be taken for the embodied principle. If it be true that Edison's telephone transmitter is such an embodied principle, Judges, in determining the scope of his claim, however it may be expressed, cannot but have regard to the fundamental character of the invention.

But, taking the language of Edison's claim as it stands, it admits—nay, calls for—the wide interpretation that has been given to it. Before the date of his patent, it was well known that diaphragms or tympans, indeed objects of all kinds, vibrate in obedience to sonorous pulses, converting variations of aerial pressure into minute mechanical movements. It was also known, but not very generally, that carbon, a substance such as Edison calls "a semi-conductor," when subjected to various degrees of pressure or compression, undergoes variations in its conducting power, and can therefore be made to act as what Edison calls "an electric tension regulator." But, until Edison showed the way, no one thought of introducing into a closed electric circuit, as part of the conductor, such a tension regulator, arranged in connection with a "tympan or diaphragm," in such a manner that sonorous vibrations, by altering the resistance of the circuit, produce electrical undulations, which, acting on a distant receiving instrument, reproduced the original sounds. It is this "combination with a diaphragm or tympan of electric tension regulators" acting in this way for this purpose that Edison claims. The idea once given, it is easy to contrive varieties of diaphragms or substitutes for them, it is easy to vary the form and construction of tension regulators, it is easy to make the combination appear very different from anything described by Edison; but, so long as "in an instrument for transmitting electric impulses by sound" there is the combination of something that vibrates to the voice and by its vibrations acts on something which "varies the resistance in a closed electric circuit," that instrument is obviously within the scope of Edison's claim.

Prof. Thompson accuses a Lord Justice of "stretching Edison's specification so as to include in it things that were invented a year afterwards by Hughes." The Professor alludes to the microphone, but he forgets to call attention to a passage in Edison's specification which the learned Lord Justice had before him, thus:—"In some cases I make use of a variable resistance resulting from greater or less intimacy of surface contact, such as would result from a disc covered with plumbago placed adjacent to a diaphragm also covered with plumbago or other semi-conducting material, so that the proximity or extent of surface contact will produce rise and fall of tension, the respective parts being in the telegraphic circuit." What is the microphone but an instrument in which "semi-conducting material" is arranged in a "telegraphic circuit" in connection with a "diaphragm," so that there is "a variable resistance resulting from greater or less intimacy of surface contact," produced by minute vibrations of the diaphragm?

Prof. Thompson does not confine his accusations to one particular case or set of cases; he alludes to "various other cases, notably the gas engines decisions, in which a similar judicial warping of patents has occurred." If it were my business, which it is not, to defend either Judges or experts, I should decline to meet broad sweeping assertions such as that which I quote. When the learned Professor thinks proper to formulate his plaint, as to a certain extent he has done in respect of Edison's patent, it may be possible to answer him. In the gas engine cases I have borne a part, and probably the Professor, looking on from outside, could see how far my conduct as an expert contributed to the "judicial warping" of which he complains. If I have sinned, it has been in good company, and the decisions arrived at, unpalatable as they may be to Prof. Thompson, seem to indicate that those with and for whom I have acted were not altogether in the wrong. To one rule I have always strictly adhered—a rule which Prof. Thompson must, I think approve—never to act as expert when I have any interest whatever in the invention litigated, or in any rival invention.—I am, sir, yours obediently, JOHN IMRAY.

28, Southampton-buildings, W.C., July 19.

The correspondence in your columns on the above-mentioned subject, and your leading article in *The Times* of the 17th have raised a question of importance. There are not many leading counsel who add to their professional ability the power of mastering thoroughly the scientific facts upon which they are "coached" for the occasion—there are very few who have the technical knowledge necessary to deal effectively with the unexpected issues which may arise—in a complicated patent case. In electrical controversies (say a telephone patent case) there are also comparatively few scientific gentlemen of eminence who are experienced in putting their views clearly before the Court. It has now been alleged (both in *The Times* and in many technical journals) that in such a suit the more wealthy of the two parties (the one may be a company with a capital of a million, the other a struggling mechanic or instrument maker) is generally found to have retained by means of a general retainer all the leading counsel who have distinguished themselves in electrical patent law, and that they, with the aid of the most experienced scientific experts available, succeed in misleading the Judges by causing them "to misunderstand patent specifications, and consequently to give unjust judgments."

I am not competent—few men are—to decide whether this has or has not been the case; but Judges, counsel, and scientific experts will agree with me that it is impossible to expect from our Judges that intimate knowledge of scientific details which will enable them always to put a right value upon the intricate technical arguments of counsel and witnesses. For this reason it has been decreed that the Court at its discretion may, and at the request of either party to a patent suit shall, appoint an assessor to assist the Court in this very matter.

Why, Sir, is this never done? It is possible that the Judge does not use his rights from a false feeling that such action might be taken as a confession of weakness, and that neither party does so for fear of incurring the odium of seeming to impute incompetency to the Judge before whom the case is to be heard. As a matter of fact, any want of scientific knowledge must obviously be apparent when a non-scientific Judge discusses difficult scientific points without assistance (as in the judgment on the late telephone case where the Judge asserted that a billiard ball in falling on a table "flattens itself to half its diameter"). If the publicity which you have given to the matter should help to dispel false sentiment and lead to the appointment of assessors in those technical cases, which are often difficult even to technical men, the

Digitized by Google

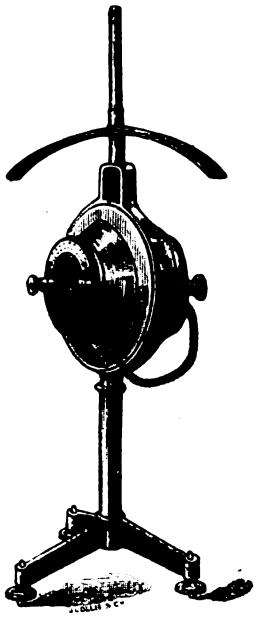
public, who, rightly or wrongly, have expressed dissatisfaction, would feel greater confidence in the administration of the Patent Laws.—Yours faithfully,

GEORGE FORBES.

34, Great George-street, West minster.

NEW REFLECTING GALVANOMETER.

We illustrate herewith a new and most inexpensive form of reflecting galvanometer, made by Messrs. Woodhouse and Rawson. The frame consists of a brass disc, supported on a pillar and ordinary tripod, and surmounted by a rod on which the controlling magnet slides up and down, and in the bottom of which the milled head fibre suspension moves. This disc is turned out on both sides, leaving the centre only one-sixteenth of an inch in thickness, and has a thin slot in it extending from the top to the centre ; this slot takes the fibre, and is enlarged at the centre to allow the mirror and needles to swing freely. The coils, which are wound, and made into a solid block by soaking in paraffin wax, are contained in two brass cases of the form necessary to give the greatest effect upon the needle ; these fit into the turned recesses, and are held against the frame plate by two screws. Two terminals are attached to the ebonite plate which closes the outside end of each coil case, and two glass discs are cemented at the inside end of the axial hole in the coils if a damped instrument is required. The coils can be wound so as to have both their resistances and magnetic effects equal, and the instrument is thus specially suitable for use as a differential galvanometer. Its construction renders the putting in of a new fibre an extremely simple matter, and enables the manufacturer to send out with it any desired number of pairs of coils of different resistances, which can be exchanged one for the other almos instantly. The instrument, while cheap, is



really capable of doing most of the work of much more expensive instruments.

AN ELECTRICAL "IN" OR "OUT" INDICATOR.

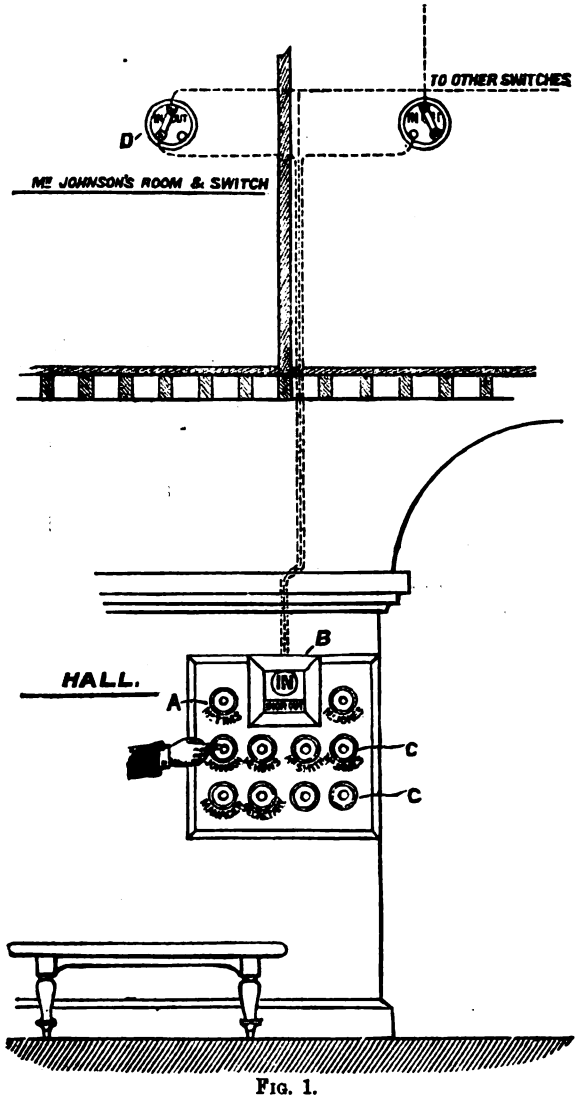


FIG. 1.

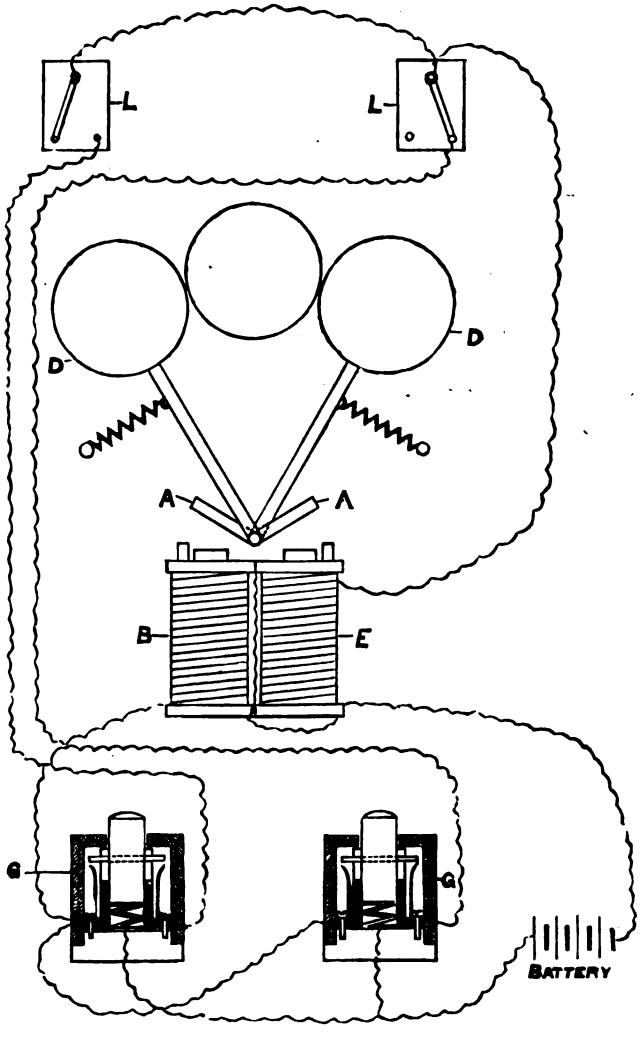

FIG. 2.

The accompanying illustrations show a new application of electricity to domestic purposes lately designed and patented by Mr. N. G. Thompson, of Messrs. Thompson, Dowsing, and Rew, 4, Queen Victoria-street. The purposes for which it is applicable are entirely distinct from, and have nothing in common with, that of the ordinary bell indicator, its object being to inform any visitor or person who may enter the hall of a building if the friend or the man of business called on is *in* or *out*, without wasting time and strength in mounting the stairs.

It is well known that in most public buildings, and almost all flats, metal indicators set by hand are employed for the above purpose, and the great advantage of this new form of electrical indi-

Digitized by Google

cator over the old mechanical system is that the indications cannot be tampered with by mischievous persons entering the hall, and also that the determination of the indicator is regulated entirely from the inmate's room. This latter advantage is well illustrated in cases of families living in flats, where it may be desired to indicate "out" at certain periods of the day without the trouble of having to send down stairs to do so.

The general arrangement of the system is shown in Fig. 1. A board, A, is placed in the hall in any convenient place, and on this is fixed a single indicator, B, and any number of pushes, CC, as shown. Each push is in electrical communication with the indicator, and also with one of a number of switches placed in the different rooms. Each push, then, has communication with one particular switch and none other, but all the pushes are connected with the indicator.

Assume, then, that Mr. Johnson has a switch in his room, as shown at D; by altering this switch to either one of two positions anybody pressing his push on the board below will observe at the indicator either one of two indications, according as Mr. Johnson has set his switch above; and the same will apply to all the other pushes. The indicator only indicates during the time of pressing the push, and shows a blank when this is released, so that no replacement of any kind is required below. The system is worked by means of ordinary Leclanché cells, it is excessively simple, and almost impossible to get out of order.

The construction of the indicator is shown in Fig. 2. The two magnets B E, with their corresponding armatures A A, and indicating discs D D, may be excited by either one single or two separate circuits. In the first case the current is sent through both magnets when both discs are required to rise, and through only one magnet when only one disc is required to rise. As one disc obscures the other it is evident that when the back disc rises only, a different indication will be shown to that when both discs rise. The question whether only one magnet or both shall be excited is ruled by the position of the switches L L in the rooms above, the pushes G G only acting as contact makers and breakers. In the second case where separate circuits are employed to each magnet only one disc rises at a time.

Another arrangement is to place one magnet on a separate and independent circuit worked by a single cell, the switches and pushes having the same functions as before. Mr. Thompson has also provisionally patented another form of indicator, the position of whose discs is not only determined by the switch above, but is also worked by the action of setting it over. The indications in this case always show either "in" or "out," and require no manipulation on the caller's part.

The interesting feature of this form is that the disc in performing its action breaks circuit, but makes contact for another circuit on the open side of the switch, which, when again placed over, repeats the action, and thus the battery is only momentarily on whilst the disc is falling over.

We have examined the form of indicator as set up at Mansion House-buildings, and it seems to us that the arrangement is one that will prove of great convenience in the majority of business houses.

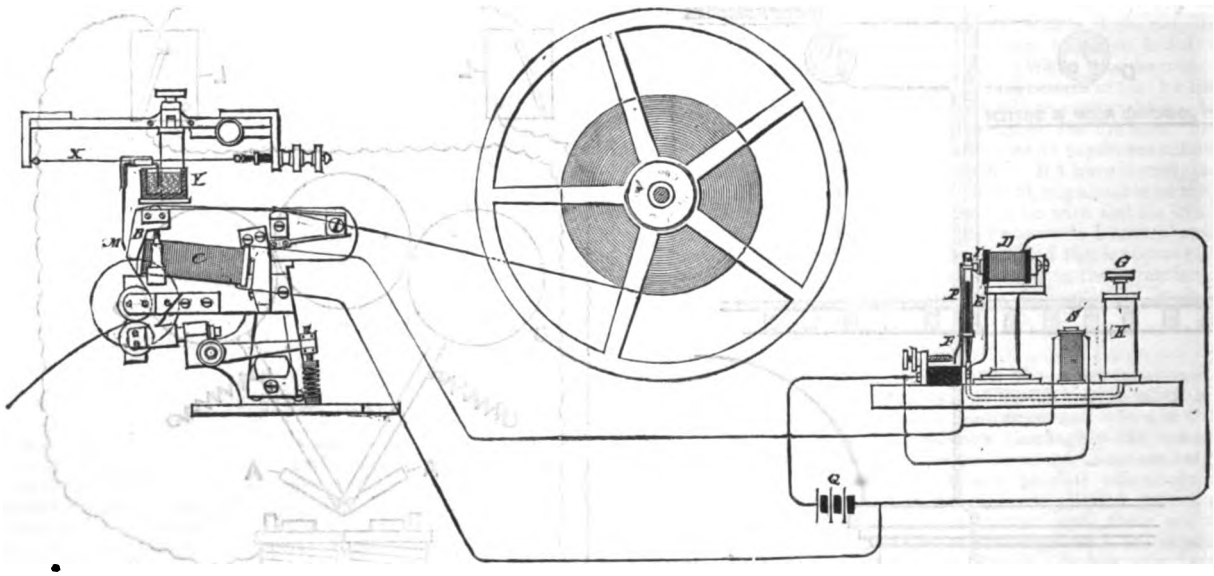
THE CUTTRISS PATENT SIPHON VIBRATOR FOR CABLES.

The use of static electricity to vibrate the siphon, with the object of preventing friction at the marking point of Sir William Thomson's siphon recorder, has always been the one defect in this otherwise most perfect and beautiful instrument; for, as is well known, in damp weather static electricity is difficult to produce and well nigh impossible to control. In such weather the operator working an electrified ink recorder must generally be confined in a room with all windows and doors closed, and frequently lamps or some sources of artificial heat are placed around the instrument to keep it dry, in order to prevent the escape of electricity. It is necessary to take this precaution even in the hot and sultry weather of August.

The paper on which the record is to be traced must also be kept in various places from cellar to garret, and oftentimes other means are resorted to so that it may be of different grades of moisture; for if the paper be too dry the electrified siphon oscillates wildly across it in its endeavour to discharge itself, while if it be too damp the siphon is discharged too effectually and the record fails.

The present invention, recently patented, obviates all this trouble by the use of magnetism, and the instrument works just as perfectly, be the weather damp or dry. By reference to the accompanying illustration it will be observed that the siphon M is slightly thicker toward the point; this is caused by a small particle of iron wire, No. 30 or 32, about $\frac{1}{16}$ or $\frac{3}{32}$ of an inch in length, fastened to it by a little shellac varnish. The magnetic recording table B, opposite the point of the siphon, over which the paper slip passes, is made partly of iron, and to the back of it is attached the electromagnet C. The addition of this magnetic table is all the alteration necessary to any recorder in order to enable the present system to be used.

The principal part of the invention is the adjustable vibrator at the right of the illustration. The glass tube E and armature I,



Cuttriss's Patent Siphon Vibrator.

which are supported by the steel rod P, are vibrated by an electromagnet D. Continuous vibration is maintained by means of the battery Q and the contact points F. The upright mercury reservoir K has a regulating screw, G, the lower end of which is made to act as a plunger; a small india rubber tube connects the mercury reservoir with the glass tube E, so that by raising or depressing the plunger the mercury can be forced and maintained at any required height in the glass tube, and by this means its rate of vibration can be changed as may be required. Whenever a new siphon is attached to the instrument it may become necessary to alter the rate of the vibration owing to the fact that even so delicate a tube as one of these siphons (which is about ·01 of an inch in outside diameter), has its own natural rate of vibration, depending upon its weight, thickness, and the amount of strain upon the wire supporting it; therefore, the impulses it receives from the magnetic table must be synchronous with its natural rate of vibration, otherwise the record will fail. When a siphon is attached to the strained wire X, and it has become filled with ink from the ink reservoir Y, the plunger is manipulated until the siphon attains its maximum arc of vibration. A perfectly steady dotted line is then obtained and will continue without any other regulation so long as it remains filled with ink.

Generally a permanent steel magnet is arranged so that one pole is opposite the magnetic table, and at about a distance of half an

Digitized by Google

inch from the siphon. This concentrates the lines of magnetic force in such a way that all the battery required is three gravity cells of low resistance. The contact points F have a spark-arresting coil, S, connected to them, so that in practice they have given no trouble, and during the two months that the instrument has been in use on the Commercial Cable Company's recorders in this city not a single failure has occurred in their action.

It was feared that the siphon might show a tendency to be attracted laterally towards the centre of the magnetic table ; but such is not found to be the case. No lateral movement can be detected, whatever be the position of the siphon when the battery circuit is broken, and the table demagnetised ; nor is there the slightest retardation experienced to its lateral movements across the magnetic field. In fact the success of the invention is so pronounced that the company is about to adopt it on all its cables as soon as instruments can be made. There is a wide field for the introduction of this system, as it can be applied to any delicate mechanism of whose movements it is desirable to take a permanent record.—*Electrical World.*

ON A NEW LAMP AND LANTERN FOR LECTURE ILLUSTRATION.

The combination of lamp and lantern described below and illustrated in Figs. 1 and 2 was designed for the purpose of obviating some of the inconveniences which are experienced in the use of most instruments of this kind. As the arrangement possesses some points of novelty, the description may be of interest to those who are in the habit of using such apparatus.

An elevation of the lamp, which is of the form patented by Prof. A. Gray and Mr. Thomas Gray some years ago, is shown in Fig. 1, and another in Fig. 2, which also illustrates the manner in which it is combined with the lantern. A small Gramme motor, M, is fixed to a cast-iron sole plate, p, which forms the roof of the lantern. On the spindle of this motor three pulleys p_1, p_2, p_3, and a drum D are fixed. Fine cords c_1, c_2, c_3 are fixed to and passed several times round the pulleys p_1, p_2, p_3, then over the small wheels at the top of the frame, and attached to the ends of the carbon holders h_1, h_2, h_3. The cords are passed round the pulleys in such a way that the revolution of the motor moves the carbons in opposite directions, and the sizes of the pulleys are arranged to give as nearly as possible a constant position to the arc. The upper carbon is guided in its up and down motion by means of a hole in the cross bar b, large enough to allow it to pass freely, and by the cross bar b_1, fixed to the top of the holder h, and sliding freely between the two tubes t, t. The lower carbon holder is guided by means of insulating washers, fixed on the ends of the rods h_2 h_3, and sliding freely between the tubes t, t, and by two similar washers fixed in the lower ends of these tubes. It will be observed that the guiding points for the two carbon slides are in all cases far apart, and thus admit of very loose and frictionless fitting, while at the same time they insure that the carbons will be maintained accurately opposite each other, and at a constant distance from the lenses of the lantern. The upper carbon clamp consists of a thick disc of brass, d, fitting into a slit in the holder, and pierced with a hole the diameter of which is a little greater than that of the carbon. The carbon is passed through the hole in this disc, which is then drawn to one side by means of the nut n, thus pressing the carbon against one side of the holder and keeping it fair. The upper holder tube is partly filled with lead, and forms the driving power which causes the carbons to feed forward as they are consumed ; but it is left hollow for such a depth as to admit a length of carbon sufficient to form a lower carbon after the normal length of carbon has been consumed. The lower carbon holder consists of a spring tube, h, slightly conical at the upper end, which when the carbon is inserted fits tightly into a conical hole in the block B. A very small length of carbon is sufficient for the holder, and hence the waste of carbon is reduced to a minimum. It is sometimes desirable to place one carbon in front of the other slightly in order to obtain the maximum amount of light, and in order that this may be readily done, or undone, as required, the holder block B is made in two parts, which are a little excentric relatively to each other, and hence by simply turning the inner part through half a turn the carbon is moved backward or forward through a sufficient distance to give the end of the positive carbon a slope to the front. The change from the centre to the excentric position, or *vice versâ*, can thus be made almost instantly, and from the outside of the lantern. This excentric tube and the electrical connections to the different parts of the motor and the carbon holders can be readily imagined from the following description, and are for simplicity omitted in the drawing. Two terminal screws, one of them well insulated, are fixed to the sole plate p of the lamp. The uninsulated terminal is connected by means of a flexible electrode, and the contacts of the bars b and b_1 with the upper carbon ; the lower carbon holder is connected by a flexible electrode with the opposite ends of the high and the low resistance coils of the magnets of the motor ; the low resistance circuit includes the armature through which it is completed by means of flexible soft brushes arranged to bear lightly, but securely, on the commutator ; the other ends of the motor coils are connected to the insulated binding screw on the sole plate.

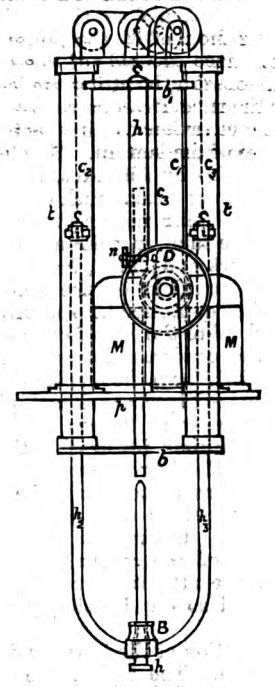


FIG. 1.—Gray's Lamp.

The electric circuit can thus be completed by connecting the poles of a generator, which may be either a dynamo or a secondary or primary battery to the two terminals on the sole plate. When the circuit is completed the powerful current which immediately begins to flow through the low resistance coils of the motor causes the armature to turn and strike the arc, which it maintains at such a length that the power of the motor is just sufficient to balance the

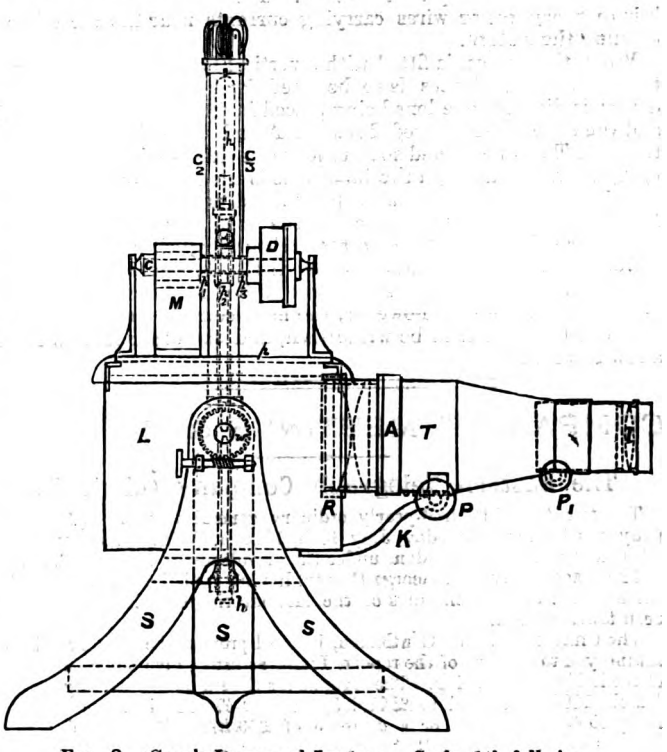

FIG. 2.—Gray's Lamp and Lantern. Scale, ⅛th full size.

gravitation power of the upper carbon holder. The feed is perfectly continuous, because as the carbons burn and tend to lengthen the arc the current decreases and gravity predominates, causing the carbons to feed together. The magnets of the motor are in the above description supposed to be differentially wound ; for a single lamp this is unnecessary, but in general more convenient, as the

Digitized by Google

instrument may then be included in an ordinary lighting circuit along with other lamps.

The drum D, shown on the spindle of the motor, is fitted with perforated partitions and partially fitted with mercury. Its function is to steady the feed of the carbons and prevent oscillations of the length of the arc.

The lantern L consists of a round or a D shaped vertical cylinder of sheet iron or brass blackened on the inside. On the top of the cylinder, and forming the roof of the lantern, is placed the base plate *p* of the lamp. Into one side of the cylinder—the flat side when it is D shaped—a collar, R, fitting the lens tube T, is fixed, and through this collar the tube T can be passed from the outside, thus avoiding the usual inconvenience of having to insert the condenser lenses from the inside of the lantern. The lens tube is supported by the collar R, and also by a bracket, K, on the end of which is fixed a pinion, P, working into a rack on the tube T, for the purpose of moving the condenser nearer to or further from the arc. In the outer end of the tube an achromatic lens, *l*, is fixed, which can be focussed by a rack and pinion, P_1, in the ordinary way. The whole is mounted on trunnions on the stand S, and the beam of light can be elevated or depressed at pleasure by means of a worm and toothed wheel, fixed to the end of one of the trunnions.

The insertion of the condenser lenses into the tube T, and the introduction of the whole from the outside of the lantern, together with the facilities provided by the rack and pinion P for changing the distance of the lenses from the arc are very convenient. For instance, in ordinary diagram illustration the magnification can be readily adjusted to suit the distance and the size of the screen, or, on the other hand, a parallel beam may be obtained for such purposes as spectrum illustration; or the image of the arc itself and the carbon points may be thrown on the screen to illustrate the mode of consumption of the carbons, the effect of placing impurities in the arc, the attraction and repulsion of currents and magnets on the arc, and so on, by simply turning the pinions P and P_1.

The peculiar construction of the lamp renders it very suitable for these latter experiments. The fact of the carbons being free to move apart renders it easy by simply introducing a fragment of a metal, or one of its salts, to obtain a long arc, and, besides, substances can be placed in the crater of the lower carbon in an instant. It is only necessary to run the carbons apart so as to break the arc, place the substance in position, and allow the carbons to feed together, when the arc will immediately be struck. The arc will, in consequence of the metallic vapour, be a considerable length, and thus well suited to show either the spectrum lines of the incandescent vapour or the action of a magnetic field in the arc. In a new instrument at present being made facilities will be given for bringing magnets or wires carrying currents near the arc without opening the lantern.

When the lantern is fitted with a vertical beam arrangement, and the same set of lenses is to be used for both purposes, the condenser is divided, one lens being placed in front of the slide box A, and the slide tube hinged between A and the other lens, so that the tube T can be turned so as to leave its axis vertical. The beam of light passing through the inner lens is then thrown up by reflection from a mirror or a large prism, and is again reflected to the horizontal after passing through the lens *l* by means of another mirror or prism. In this case the rack into which P works is fixed to the part of T, which passes through R. For experiments which require a vertical beam, a separate tube, fitted with lenses and reflectors complete, is, however, the most convenient arrangement. The one tube can then be withdrawn, and the other introduced in a few seconds.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The twenty-eighth half-yearly ordinary general meeting of this Company was held on Thursday, July 15th, 1886, at Winchester House, No. 50, Old Broad-street, London, under the presidency of John Pender, Esq.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting, and the minutes of the last meeting and the report having been taken as read,

The CHAIRMAN said: Gentlemen, before I propose the formal resolution asking you to approve of the report, I will, as usual, give some particulars of the half year's working. The revenue for the six months ending the 31st March, 1886, amounted to £341,405, against £371,682 in the corresponding period of last year, or a decrease of £30,277. You will observe on reference to the accounts that there is a decrease in the return from our investment in the South African Company of £1,950. Owing to diminished receipts the South African Company has been able to pay a dividend of only 6 per cent., as against 7 per cent. in the previous year. Our Indian traffic has been fairly maintained, but the traffic to countries beyond India has declined since December last. The chief cause of our decreased receipts arises from the absence in the past half year of political and other events which in 1885 augmented our Indian and Egyptian traffic to an exceptional extent. The total working expenses amounted to £92,244, against £91,599 in the corresponding period of 1885, being an increase of £645. But in this half year are included several items of an exceptional character, such as expenses of removing into new offices, £265; expenses relating to negotiations in France, Germany, and Egypt, £940; expenses *re* Government protection of submarine cables, £45; cost of transfer of Trieste-Corfu concession, £316, making a total of £1,566. There is also charged to revenue account an amount of £1,788, the cost of duplexing the Zante-Alexandria cable. If we exclude these exceptional items the total working expenses for this half year, as compared with the corresponding period of last year, would show a considerable decrease. The general expenses in London were £8,773, against £7,617 in the corresponding period of last year, being an increase of £1,156. The principal items of increase are—offices expenses, £229; rent and taxes, £725; and repairs and renewal of furniture, £237. This is mainly due to our having removed to larger and more commodious offices, which we found were absolutely necessary to carry on the business of this Company, grown, as it has, within the last few years. Salaries and wages, stationery and printing, and law charges, show decreases amounting in the aggregate to £176, and working expenses at stations amount to £64,439, against £65,582 in the corresponding period of last year, or a decrease of £2,143. With reference to the items shown separately on the revenue account, use of patents shows a decrease of £1,600. The amount written off for depreciation of cable stores this time is £4,200, against £2,795. We have carried £5,000 to maintenance ships reserve fund, against £6,000 for the corresponding period of 1885. Expenses attending repairs and renewals and laying of cables amount to £41,637, against £44,815 for the corresponding period of last year, or a decrease of £3,178. It will be seen on reference to Abstract C that full details of the work done by our ships are given. Numerous important repairs have been effected, and, in addition, the "Volta" steamship has laid two new 3-core cables across the Straits of Messina, the cost of which is taken from revenue. But a large part of this sum is due to the sudden breaking of both our Bombay cables in 800 fathoms during a cyclone. These are now repaired, of course, and are in working order. After charging all expenses, including income-tax, providing for interest on debentures, debenture stock, and preference shares, we are enabled to pay a dividend of 5 per cent. with a bonus of 1 per cent., or at the rate of 6 per cent. per annum, and to carry to general reserve fund £70,000, leaving a balance of £4,079 to be carried forward to next account. I think, gentlemen, you will agree with me that this, upon the whole, is a very satisfactory account to lay before you to-day. Now, gentlemen, we are making a new departure in regard to rates arising from the Conference which was held last year at Berlin. On all sides we hear—"Only reduce your rates, and you will have a largely increased revenue." We are very anxious to reduce the rates, but we think the risk ought not to be entirely with the Company, but should be shared by those who want reduced rates. Governments, even, are interfering in trying to get reduced rates. What we are now trying to establish, both in Australia and in other parts, is this: We say to them, if they will guarantee us such a rate of traffic or returns as we have been enjoying during the last three years, they may make the tariff pretty much what they please. In other words, we are endeavouring to establish a system which will be practically a guaranteed rate for the proprietors of these companies, and which at the same time would be an enormous advantage to the different Governments and the telegraping public of those Governments, because they would be able to reduce the rates to an extent which would be simply impossible for the Companies without this guarantee. These negotiations are going on at the present time with Australia, and although they are as yet looked upon with some little shyness, I think those who represent the colonies and who look carefully into the question, are satisfied that this must finally be a solution of the question of a reduction of rates, and when that occurs you will practically be enjoying as proprietors of this Company a guaranteed rate of interest upon your shares. Gentlemen, I refer to that matter because it is very much occupying the thoughts and the time of your Directors at the present moment, and I am hopeful that those negotiations will make such progress as by-and-bye will be very beneficial indeed to the Company. I see calculations made from time to time as to our property, but there is one thing you may be perfectly satisfied about, viz: that telegraphy must grow. Politics and commerce alike demand it. Those who talk of anything like a decline in telegraphy speak nonsense. Human nature is in accord and harmony with telegraphy, which will and must grow. As nations grow so also will telegraphy, and therefore I have no fear as to the calculations of those who talk about our going back, and that our stocks must be reduced in value. I have no sympathy with them at all, and depend upon it as long as telegraphy has the hold which it has at the present time upon the public generally there is no great fear of its declining, unless unnecessary and undue competition arises, and that is a question which we shall take as much care as we possibly can to avert.

Now, at the Berlin Conference—I think I mentioned this to you last year—an important question arose about Egypt. I went out to that country in the spring of this year, and saw the Egyptian Government on the subject, and I am pleased to say that what we supposed was going to result in a considerable annual payment from the Company to the Government was entirely set aside. We are therefore precisely in the same position to-day as we were in before we went to Berlin, and as we consider our position a very strong one, should the question again arise, if we have to give something we shall also get something in return. Depend upon it, your interests in that respect will be carefully guarded. I think these visits to different Governments and stations abroad are calculated to do good in many ways. All our stations are in the most perfect working order. Visits to them occasionally give encouragement to our young men, and I find when we compare our stations with those of other nations we as Englishmen have every reason to be proud.

Digitized by Google

We received intelligence yesterday of a company with which we are in very close alliance, namely, the Direct African Telegraph Company. We received yesterday a congratulatory message from the governor of Sierra Leone. Probably within two or three weeks the whole line will be laid, and when completed, that system will become a feeder for our Eastern system from Lisbon. Therefore, as far as I can see, we are at the present moment in a very satisfactory position. Since I had the pleasure of addressing you last the Direct African concession has come before the Government. There were some remarks made on that occasion in the House of Commons by a gentleman who was interested in an opposition company to Australia. He admitted that if this West African concession were passed it would be the deathblow to his scheme. As that scheme was of a nature which I think was perfectly uncalled for and unnecessary in any sense, I am very glad to find that our concession was approved, and it ought to have been, because there is no bargain ever made with a Government which has been so straightforward, and so much in the interest of the public generally. I am pleased to say that the concession passed through the hands of three English Governments, and was checked in every possible way, and I am glad to find that the Secretaries of the Treasury of those respective Governments defended it in the House of Commons in a way which must have been very unsatisfactory to those who challenged it, but very satisfactory to those who were interested in it. Now, gentlemen, with these remarks, I beg to move :—

"*That the printed report and accounts of the Directors to 31st March, 1886, submitted to this meeting, be, and the same are hereby, received and adopted. That a dividend on the preference shares of the Company to 30th June, 1886, at the rate of 6 per cent. per annum be paid, less income-tax, and that in accordance with the Directors' recommendation a dividend be, and is now, declared of 2s. 6d. per share, with a bonus of 1s. per share, both free of income-tax, on the ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of 6 per cent. on those shares for the year ended 31st March, 1886.*"

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second the resolution.

The CHAIRMAN: Now, gentlemen, if there is any shareholder in the room who desires to put any question to me, I shall be happy to answer him before putting the resolution. No one rising to address the meeting, he continued: Well, gentlemen, the resolution has been moved and seconded, and those in favour of it will please signify the same in the usual manner. To the contrary? Carried unanimously. That, gentlemen, closes the business of the meeting so far as the resolution is concerned. I might say that you will notice that we have met in a new hall to day. I hope you will all find it to be so much in the centre of the City that it will meet the requirements of the various companies who have found it hitherto rather onerous to carry their books and papers down to the Cannon-street Hotel.

Mr. JOHN NEWTON: Mr. Chairman, I have very much pleasure in moving a vote of thanks to you and your colleagues for the manner in which you have conducted the business of the Company during the past half-year and for some time past. I think that the manner in which Governments are dealing with the property of shareholders in telegraph companies is scarcely fair to telegraph shareholders, and I also think our Directors have protected our interests as much as possible under the circumstances. We are not fairly treated by the governing bodies of the country, seeing the immense value and importance that we have been to all business transactions and all social intercourse between nation and nation; and it is unfair that we should be so trammelled and hampered in our attempts to get a fair and proper remuneration for the capital invested in these companies [hear, hear]. I think the manner in which you have protected our property under the circumstances in which we are assailed deserves a hearty vote of thanks on this occasion, which I beg to move.

Mr. MUIR: I second that.

The SOLICITOR (Mr. Burt): Mr. Newton has moved that a vote of thanks be given to the Chairman and Directors for their conduct of the Company's business. Those in favour of that will please signify the same in the usual manner. To the contrary? Carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I return you our best thanks. I may say that we take very great pride in the progress and prosperity of this Company. We have a great deal to contend against. As I have said to you, telegraphy is growing, but every one seems to think that it ought to be much cheaper than it is. While we are protecting your interests we are also most anxious to give such an impetus to telegraphy as we can by reducing the rates, but consistently with your interests. Depend upon it, we shall do all we can in the future to maintain the success of this Eastern system of telegraphy, and in a way which will be of benefit to the world and advantage to the shareholders, who have done so much. I beg to thank you. I may tell you that our offices are now in this building, and if there is any gentleman who wishes to look round them I think he would get some idea of the amount of work that is going on to keep this system in active operation. We shall be very pleased, on application to the Secretary, to show the offices to any gentlemen who wish to see them.

The proceedings then terminated.

Telegraph Construction and Maintenance Company (Limited).

In accordance with the resolution of the general meeting of 28th Feb., 1871, a half-yearly general meeting of this Company was held at 38, Old Broad-street, on the 20th inst., Sir Daniel Gooch, Bart., in the chair.

The MANAGER (Mr. Shuter) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, at these meetings, as you are aware, we do not present any accounts or report to you, but simply give you shortly a statement of the work done during the past few months. I may tell you that during the half year we have laid a cable 398 miles in length between Penang and Singapore, replacing an old cable that was picked up. We have also laid 1,130 miles of cable along the West Coast of Africa. When completed, this cable will embrace a length of about 2,000 miles, and will connect the African settlements from Bathurst to the river Niger. We have manufactured during the year about 2,100 miles of cable. I may say that the prospects for the next half year are not so flourishing, but we must trust to fortune to get us more work. The only other point I need refer to is as to the question of electric lighting. That has been in operation for three months, but legal difficulties have been raised as to noise or annoyance, or whatever you may choose to call it, with some of the houses closely adjoining the works. These difficulties are still matter of litigation, and therefore I am not able to go into the subject. I must leave that to the next general meeting. I do not know that I have anything more to say, but I shall be glad to answer any question.

Mr. HOLDSWORTHY: You say there is litigation. Is the light still going on?

The CHAIRMAN: The lighting is still going on. We do not know what the result may be.

Mr. HOLDSWORTHY: No, I only asked for the fact. I should be sorry to ask any question as to the litigation.

The CHAIRMAN: As far as the light is concerned, it is a perfect light. The only question is, can we produce it without annoyance to our neighbours? Is there any other question, because we have no resolution to move at these meetings?

Mr. GIBSON proposed a vote of thanks to the Chairman and Directors, to whom, he said, the shareholders were very much obliged for their care and attention to the affairs of the Company.

The CHAIRMAN: We are very much indebted to you, and we hope that we may be as prosperous in the future as we have been in the past. We shall do our best, at any rate, to assure that. I now declare this meeting closed.

India Rubber, Gutta Percha, and Telegraph Works Co. (Limited).

A half-yearly general meeting of this Company was held at the Cannon-street Hotel on the 20th instant, "for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax." Mr. S. W. Silver presided.

The SECRETARY (Mr. W. J. Tyler) read the notice convening the meeting.

The CHAIRMAN: Gentlemen, the notice conveys the object of our meeting to-day. As our books are made up but once a year, we have no results to present to you. The general report I have to make to you is that business, considering the generally depressed state of trade, is fairly good. Our works are in excellent condition and order, both in England and France, and our steamers are fully occupied. Without detaining you further, few as these remarks are, I will move that this interim dividend of 5 per cent. be paid.

Mr. NEIL BANNATYNE seconded the motion.

The CHAIRMAN: It is payable to-morrow. He then put the motion in the usual way, and it was carried.

Mr. CATER gave notice that at the next general meeting of the Company he would bring forward for the consideration of the shareholders the question of the large amount which was set aside for the remuneration of the Directors. At the last general meeting the amount was £1,100 each, and that had been increased since then by the augmentation of the direction.

The CHAIRMAN: I think you are in error as to the increase. There has been no increase.

Mr. CATER said he was very glad to hear it. The next balance-sheet would show what the amount was.

Dr. D. H. SMALL moved a vote of thanks to the Chairman and Directors for the continued success which attended the Company. He had been to the works at Silvertown, and had been very much pleased at what he had seen. He believed that the cables turned out by the Company would be as good as those manufactured by any other company.

Mr. TREBLE seconded the motion, which was carried.

The CHAIRMAN: In the name of my brother Directors and myself I would thank Dr. Small for the observations he has made, and for the vote of thanks proposed. I assure you that the attention that has been paid hitherto to your affairs shall, if possible, be increased in future.

Mr. PAINE: Would the Chairman kindly tell us what amount of fees each Director receives per annum?

The CHAIRMAN: The minimum is £2,000, and the maximum £5,000.

Mr. PAINE: Is not that for the whole Board?

The CHAIRMAN: Yes. The business is now at an end, gentlemen.

Anglo-American Telegraph Company.

Report of the Directors, to be presented at the ordinary general half-yearly meeting of the proprietors, to be held at the Cannon-street Hotel, on Thursday, the 29th inst, at 2 o'clock p.m. :—

The total receipts from 1st January to the 30th June, 1886, including a balance of £4,096. 13s. 7d., brought forward from the last account, amount to £116,737. 11s. 9d. The traffic receipts show a decrease as compared with the corresponding period of last year of £22,321, consequent upon competition, a reduced tariff, and continued depression of

Digitized by Google

trade between Europe and America. The total expenses of the half year, including repair of cables, &c., as shown by the revenue account, amount to £46,813. 12s. 7d. The Directors, under the powers conferred upon them by the Articles of Association, have, before declaring the net profits, set apart the sum of £50,000 to the renewal fund, leaving a balance of £19,923. 19s. 2d. One quarterly interim dividend of 5s. per cent. on the ordinary stock, and of 10s. per cent. on the preferred stock, was paid on the 1st May, 1886, absorbing £17,500. It is not proposed to declare any interim dividend for the past quarter, but to carry the balance of £2,423. 19s. 2d. forward to the next account. The Company's repairing steamship "Minia" has been engaged during the past half year in the repair of the Northern Placentia and Duxbury cables, and also of the Direct United States Cable Company's short section cable between Torbay and Rye-Beach. The whole of Company's cables and land lines are in good working order, with the exception of the Duxbury cable, which was again broken on the 2nd instant. In the month of May last, a Conference was summoned by the French Government and held at Paris, at which the principal European and American States were represented, for the purpose of reconsidering the clauses of the Convention of 1884, for the protection of submarine cables, which had been modified at the instance of the English Cable Companies by the Acts of Parliament passed in 1885. A committee was appointed by the Conference to examine the details of the modifications, and to hear the views of the Telegraph Companies on the subject. The delegates of the companies (including the Managing Director of this Company) attended the committee, and after much discussion the Conference adopted declarations which fairly satisfied the requirements of the Cable Companies. The reduction of tariff from 2s. to 1s. 8d. per word introduced by the Commercial Cable Company (Mackay-Bennett cables) on the 24th December, 1884, resulted in a large decrease in the gross revenue produced by Atlantic cable traffic. Nevertheless, it was determined by the associated Cable Companies to give the reduced tariff a fair trial, in order to avoid a war of rates, and to determine as early as possible whether the reduction would result in any remunerative increase of traffic. After more than a year's trial it was found that the very contrary was the case, and as the rival company resorted to means to obtain a greater share of the traffic than the possession of two cables fairly entitled them to, the Directors of the associated companies came to the conclusion, that it was necessary in the interests of their proprietors to adopt a low rate. Accordingly on the 5th May, 1886, the rate was reduced by the associated Cable Companies to sixpence per word, and by special arrangement with the Western Union Telegraph Company of America this tariff was made to extend to all the principal cities and towns in the United States and Canada. For press news a special rate of threepence per word between London and New York was also adopted. On the same date the tariff of the Mackay-Bennett cables was reduced to one shilling per word. The effect of this important reduction of rates by the associated companies has been a very considerable augmentation of the traffic, much larger indeed than was anticipated as a first result, amounting to over 110 per cent., and although the total receipts have greatly decreased, the Company is earning sufficient to pay its working expenses, and to place such a sum to the credit of the renewal fund as with the accruing interest will soon bring that fund up to £1,000,000, the limit fixed by the proprietors at the last half-yearly meeting. The unexpected increase in the volume of traffic immediately upon the introduction of the sixpenny tariff has induced the Directors to consider the expediency of adopting permanently a system of low rates. The associated companies possess between them no less than eight cables across the Atlantic, having a carrying capacity which for practical purposes is unlimited. With such an extensive system, it is obviously their interest to encourage a very large traffic at low rates, and by so doing prevent a further multiplication of unnecessary cables. By the recent reduction of rates cable customers and the public have the opportunity of answering the question upon which the future rate between Europe and America will have to be decided, namely, whether there is a sufficient inherent development in the cable traffic to and from America, to warrant a low charge being permanently established. If there be such development, and the public respond to the desire of the associated companies to continue working at low rates, it will be to the interest of the companies to do so, as they only desire to earn a reasonable return upon the capital invested, and prevent further wasteful competition. The Directors would remind the proprietors that the Company has now been in existence for over twenty years, and that although high rates were in the first years of the undertaking an absolute necessity, and were not at that time objected to by any important class of the community, they have since been found, whenever adopted, to produce continuous competition, useless multiplication of cables, and loss of money to all the companies interested. The Directors believe that sooner or later a low tariff will be a necessity, and that by "taking time by the forelock" and making an earnest effort now to establish it, they will secure the cordial approval and co-operation of their customers and the public, without which so important a step could never be successfully adopted.

CRICKET.

Messrs. Willans and Robinson *v.* Messrs. Woodhouse and Rawson.

A cricket match between the employés of the above firms was played on July 17th, on the village green at Thames Ditton. The party from the works at Hammersmith arrived at Thames Ditton at 10:30, when they were conducted over the Ferry Works by J. C. Peache, Esq., the manager, and had an excellent opportunity of inspecting the many interesting types of engines in course of construction for Her Majesty's Government and others. Amongst the various improvements we noticed the plan of casting the bed-plate of engine and dynamo in one solid piece, thereby securing great strength with considerable reduction of weight. About 11:30 an adjournment was made to the green, where, in spite of heavy rain, a start was made at 12:45. The electricians proved rather too strong for the engineers, who narrowly escaped being beaten in a single innings. The first three wickets of the visitors realised the useful amount of 130 runs, after which the remainder only added 36. At 3:0 an adjournment was made to the Red Lion for lunch, where the visitors were entertained by their opponents, and sat down to an excellent repast. Play was continued till 7 o'clock, with the following result. We must not omit to mention the excellent wicket-keeping of the local team and the free hitting of Thomas, Ward, and Rawson. A fine afternoon completed a most enjoyable day for the visitors, who have to thank their courteous opponents for their thoughtful hospitality. Score :—

Messrs. Woodhouse and Rawson.—B Thomas, st Deane, b. Sands, 20; C. R. Chambers, run out, 13; H. W. Ward, run out, 49; W. S. Rawson, b. Deane, 47; W. Long, st. Reeves, b. Bounds, 0; J. Sinclair, b. Bounds, 0; M. S. Chambers, run out, 16; J. A. R. Milton, c. and b. Deane, 0; L. Parsons, st. Reeves, b. Thistlewaite, 0; R. Price, st. Reeves, b. Thistlewaite, 5; A. E. Ruddock, not out, 1; extras, 15; total, 166.

Messrs. Willans and Robinson, *1st innings.*—W. Deane, c. Rawson, b. Thomas, 7; S. Hiscocks, b. Rawson, 0; Thistlewaite, b. Rawson, 5; A. Sands, b. Rawson, 12; H. Reeves, b. Rawson, 0; G. Reeves, b. Rawson, 0; J. Miller, c. Sinclair, b. Thomas, 3; L. Bounds, not out, 6; W. Adams, b. Rawson, 7; E. Kedge, b. Thomas, 4; W. Rodwell, c. Renddock, b. Rawson, 2; extras, 3; total, 49. *2nd innings.*—W. Deane, not out, 24; H. Reeves, run out, 2; G. Reeves, st. Long, b. Ward, 0; J. Miller, not out, 6; L. Bounds, c. and b. Sinclair, 4; E. Kedge, st. Long, b. Ward, 0; W. Rodwell, c. Sinclair, b. Ward, 4; total, 40.

BUSINESS NOTICE.—Messrs. Swete and Main, Electrical Engineers, have removed from Battersea to 11, Queen Victoria-street, E.C.

NOTES.

JAPAN.—A factory for the manufacture of telegraph wires and appliances is to be established at Tokio, Japan.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 23rd inst. amounted to £2,688.

PRESIDENT GREVY.—The Elysée and Mont-sous-Vaudrey are to be telephonically connected during the stay of the President of the Republic in Jura.

Mr. C. H. B. PATEY, C.B.—The Queen has been pleased to approve the appointment of Mr. C. H. B. Patey, Secretary Postal Telegraphs, to the Civil Division of the Order of the Bath.

ELECTRIC LIGHTING BY A GAS COMPANY.—The directors of the Waltham, Mass., Gas Light Company have determined to lay down an electric lighting plant for central distribution at a cost of $20,000.

PERSONAL.—Mr. Ernest Danvers has resigned his position of Inspector-General of Columbian Telegraphs, on account of the bad financial state of the country, and has removed to Caracas, Venezuela, South America.

SHEFFIELD *v.* BIRMINGHAM TELEGRAPHISTS.—The annual cricket match of these clubs was played on the ground of Messrs. Bass and Co., Burton-on-Trent, last Saturday. The result was in favour of the Sheffield team.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 23rd inst. were £2,118, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE TELEPHONE IN SCOTLAND.—The National Telephone Company have decided to immediately commence the laying of several telephone lines between Dundee and Glasgow, with branch lines to Edinburgh and other towns in that part of Scotland.

GERMAN PRESS RATES.—We hear that the the new rules regulating the tariff for press messages in Germany are causing much dissatisfaction. The rules are in many cases not a little arbitrary, and their effect is to considerably increase the cost of the service.

RYDE PIER ELECTRIC RAILWAY.—The directors of the Electric Railway Company of Ryde have issued their report for the last six months. The working of the railway has given great satisfaction, and the financial result exceeds the anticipations of the promoters.

TEMPORARY ELECTRIC LIGHTING.—Mr. F. Geere Howard has carried out a large number of temporary installations this season by means of the Holmes-Bourke primary batteries, the number of lamps used varying from thirty to eighty, of twenty candle-power each.

REMOVING OVERHEAD WIRES.—At Evansville, Indiana, the local telephone company having failed to comply with an order of the municipality to remove their overhead wires by a given date, the whole of the wires were cut and the poles were removed by the police force.

IMPORTANT TO ELECTRICIANS.—The subject for the next international competition for the King of the Belgians' prize of 5,000 dollars is "The Progress of Electricity, applied to motive power and illumination; its application and economical advantages." The essays have to be written in French.

EASTERN TELEGRAPH COMPANY.—This company notifies that the coupons on their Five per Cent. Debentures, due on 1st August proximo, will be paid after that date at the banking house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons should be left three clear days for examination.

LEICESTER EXHIBITION.—On Thursday last the models and certificates awarded to the successful exhibitors at the Leicester Exhibition, were presented at the Royal Institution. Messrs. Woodhouse and Rawson obtained a medal for their electrical exhibit, and a certificate for their Cunynghame, Woodhouse, and Rawson automatic cutouts.

MEXICAN TELEGRAPH STATISTICS.—The following particulars of the length of telegraph lines in the Republic are taken from a paper published in the capital:—Federal Government lines, 10,937 meters; State lines, 1,653 meters; railway line, 4,431 meters; private companies, 3,301 meters; and submarine cable, 703 meters.

THE FALLS OF CLYDE.—There is, it is said, a movement on foot just now for utilising the celebrated Falls of Clyde for generating electricity. Turbines for working the dynamos are to be fitted up at Stonehouse, whence the electric current will be transmitted by cables to the town of Lanark, where it will be used for lighting and other purposes.

REDUCTION OF GERMAN TARIFF.—The Director-General of Posts and Telegraphs in Germany has recently announced that the tariff for messages from Germany to the principal towns of the United States *viâ* Emden will be reduced from 1m. 65 to 65 pfennigs per word. A similar reduction will be made in the case of messages to Mexico and South America.

SCIENCE IN THE NEW PARLIAMENT.—Sir John Lubbock, Sir Henry Roscoe, and Sir Lyon Playfair appear to be the chief representatives of physical science in the Parliament just elected. Sir U. Kay-Shuttleworth, Mr. Nevil Story-Maskelyne, and Dr. Farquharson, who are known as writers on scientific subjects, may also be included in the number.

ELECTRICITY AT THE HELM.—The well-known French firm, Breguet, are at present engaged on some experiments which have for their object the applying of electricity to the working of the helms of ships. If the results are satisfactory, we may expect to hear shortly that four of the new packets of the General Transatlantic Company are steered by means of electricity.

WEST AFRICAN CABLES.—We are informed that the Silvertown Company's ships, the "Silvertown" and "Dacia," have successfully landed the shore ends for the Grand Bassam-Accra section for the West African Telegraph Company. As this work was finished on the 12th inst. we may expect from day to day to hear of the completion of the above-named section.

UNIVERSITY DEGREES.—In the recent examination at the University of London in electricity the following gentlemen received the degree of D.Sc.:—(*a*) Treated experimentally, Henry Stroud, St. John's College, Cambridge; (*b*) treated mathematically, John Thomas Riley, Mason College, Birmingham; (*c*) treated experimentally and mathematically, Robert Mullineux Walmsley, Technical College, Finsbury.

ALWAYS GRUMBLING.—The telephone is supposed to save the valuable time of business men; but when London subscribers have to stand for ten or fifteen minutes with the receiver up to their ear, waiting to be "put on," this can scarcely be called a saving of time. The fact is, that more trunk lines are required, considering the large and increasing number of subscribers in the London district.

PARIS GAS SHAREHOLDERS.—Considerable excitement has prevailed this week amongst the holders of gas stock and shares in Paris, owing to the uninterrupted success of the

Digitized by Google

electric light installations that have recently been put up in the principal places of amusement and elsewhere. As one of the results of the scare, a marked depreciation in the value of gas shares in the French capital has been noticeable.

NARROW ESCAPE.—The Archduchess Frederick and her two little daughters had a very narrow escape from death by lightning last week. During a violent storm, when they were in one of the drawing rooms of the Palace at Pressburg, a powerful current of electricity struck the building, and, entering the room where the Princesses were sitting, knocked down a part of the wall only a few feet distant from the chairs they were occupying.

THE LATE MR. FAWCETT.—In memory of the late Professor Henry Fawcett a drinking fountain, subscribed for by women grateful to him for his work on their behalf, was formally unveiled in the Thames Embankment Gardens on Tuesday afternoon. The memorial is placed opposite Cleopatra's needle. Louisa Lady Goldsmid performed the ceremony, and the subsequent speakers were Lady John Manners and Mrs. Garrett Anderson.

THE LEEDS MUSICAL FESTIVAL AND THE ELECTRIC LIGHT. At a meeting of the Leeds Musical Festival Committee, held on Tuesday afternoon at the Town Hall, a resolution was unanimously passed in favour of employing the incandescent electric light at the forthcoming festival. A sub-committee was appointed to bring the matter before the Electric Lighting Committee of the Town Council, who it is confidently anticipated will give effect to the resolution.

METEOROLOGICAL OBSERVATIONS. — The *Centralblatt für Electrotechnik* says that the Austrian Society of Meteorology is planning an undertaking which promises to be of great service to meteorology and the kindred sciences. This is the erection of an observatory on the summit of the Tomblick in the Tanern, at an elevation of 3,100m. above sea-level. It will be the highest observatory in Europe, and is to be provided with the best instruments and registering apparatus.

THE PROPOSED CABLE VIÂ THE ANTILLES.—With reference to this cable, which formed the subject of our leading article last week, we learn that the national sentiment is to be consulted to a greater extent even than we imagined. The conditions of the concession stipulate that the cable is to be manufactured in France, shipped and laid by a French vessel, and worked by French hands. We would also suggest that none but French capital be embarked in the venture.

THE TELEPHONE IN AUSTRIA.—The telephone between Vienna and Brünn, a distance of one hundred miles, commenced working early this week, and is a complete success. The system employed is that of Ryssellberghe, which allows of the use of ordinary telegraph wire. Preparations are already being made for the establishment of regular telephonic communication between Vienna and Pesth, a distance between two and three times as great as between Vienna and Brünn.

TELEGRAPH PATENTS IN MEXICO.—A patent has been granted by President Diaz, dated June 12th, to Señor Don Francisco Javier Estrada for a system of telegraphic communication with railway trains in motion, the patent to extend for a period of ten years. "Is it possible," asks the *Two Republics*, "that Edison's latest telegraphic invention should have been duplicated in Mexico at the same time that some American inventors claim to have anticipated him?"

STORM WARNINGS.—M. Hervé Mangon, member of the Institut and president of the Congrés Officiel de la Meteorologie Française, has expressed a wish that the transatlantic cable companies should accord the benefit of a special tariff to the meteorological offices of Europe and America for the transmission of storm warnings, the important service of which to the shipping interest of the world, thanks to the efforts of General Hagen and the *New York Herald*, has been so much appreciated during the last ten years.

A NEW CONSTANT CELL.—Mr. H. P. Laurie has devised a cell which he claims to be practically constant. The negative plate consists of platinum, and the positive of cadmium. A solution of cadmium iodide containing free iodine is employed. The electromotive force of the cell remains constant at 1·076. There is, however, one small feature yet to be mentioned which is necessary to ensure the constancy of the cell, and some people would perhaps consider this feature as rather a disadvantage than otherwise. The cadmium plate must be rotated by clockwork, at a speed of from two to three revolutions per second.

M. BOISSELOT'S TELEPHONE.—This instrument, which was exhibited at the recent meeting of the Societé Internationale des Electriciens, is a modified form of the Bell, and is intended for use as a magneto transmitter as well as a receiver. Its peculiarity consists in the fact that the coils are wound upon soft iron cores, attached to the centre of an iron diaphragm. The iron cores are magnetised by a powerful horseshoe pattern steel magnet, which is fixed in such a way that it does not interfere with the movement of the diaphragm. M. Boisselot claims that this instrument is as good a receiver, and far better as a magneto transmitter, than anything previously devised.

WATER MAINS STRUCK BY LIGHTING.—Instances have more than once been recorded where water mains, being struck by lightning, have burst. It is scarcely probable that this is a direct result of the electric action; more probably the effect is due to a certain amount of steam being suddenly generated. A case has just been reported from Halifax, N.S., of a somewhat different character. A fire hydrant was struck by lightning, and notwithstanding the apparently easy passage to earth afforded by its connection with the main, the street pavement was torn up in a direct line for the distance of two blocks of houses. The tract thus opened seems to have been of considerable depth, for we are told that "large rocks were thrown to the surface."

MORE LAW.—We are at liberty to state that an action has been commenced by the Edison and Swan Company against the Jablochkoff Electric Lighting Company and Mr. Holland, of the Albert Palace, for selling and using the Victoria incandescent lamps, manufactured by the Anglo-American Brush Electric Light Corporation, and that steps are being taken to enable the Anglo-American Brush Electric Light Corporation to defend the action as third parties, and that the Corporation are giving full indemnities to all their customers. Also that the Anglo-American Brush Electric Light Corporation have commenced a suit against the Edison and Swan Company for injunction and damages for infringement of the Lane-Fox patents for incandescent lamps.

A FLOATING EXHIBITION.—A committee has been formed in Paris, under the patronage of the Syndicate de l'Industrie et du Batiment du Department de la Seine, and under the direction of M. de Berny, to organise a floating exhibition to go to different parts of the world, showing the products of the various industries of France. A vessel of 3,900 tons, named "La Sarthe," has been placed by the Minister of Marine at the disposal of the committee, which is forthwith to be fitted up in a manner suitable to carry out this novel experiment in the way of advertising. The vessel, which is to be lighted by electricity, will depart from Havre towards the end of the year

Digitized by Google

on its first journey, and will call at the principal towns on the coast of Central and South America.

THE TELEPHONE IN MEXICO.—According to advices from the city of Mexico there appears to be little field for the telephone in the province of Lucatan, whatever inducements there may be in other parts of the Republic. When the telephone was first inaugurated at Merida the enterprise had over one hundred subscribers. At present, while the line has been extended to Progresso, the patronage is much reduced, the list only comprising 78 subscribers, of whom sixty-four are in Merida and fourteen in Progresso. The falling off of subscribers is attributed to the unsatisfactory state of business. Several large mercantile failures have occurred of late, which are attributed to the lack of banking facilities rather than to the inherent weakness of the firms in question.

WHAT IS ELECTRICITY?—The above question is propounded by Prof. Le Corguille as the heading of the first chapter in a series of elementary lessons which he is writing for the *Moniteur Industrielle*. After having our expectations aroused in this way, it is not a little disappointing to find that the learned Professor is only about to exhibit those interesting but decidedly mouldy relics the one-fluid and the two-fluid theories. Upon this side of the Channel, at least, it is tolerably well understood that so far as they could be supposed to afford any answer to the Professor's query, the fluids (one and two) have long since departed this life; and have been afforded honourable burial along with Caloric and Phlogiston, and Newton's Luminous Corpuscles, *et hoc genus omne*.

TELEPHONE EXTENSION.—Mr. Graham, the superintendent of the South England Telephone Company, attended the last meeting of the Irthlingborough Highway Board, and asked permission to erect poles west of the town of Wellingborough through the villages of Doddington, Earls Barton, and along the highway into the parish of Billing. He said it was the intention of the company to connect Wellingborough with Northampton, and then further to extend the poles to other centres of the shoe trade, such as Kettering, Rushden, and Higham Ferrers. A discussion arose on the terms on which permission should be given; but finally the board unanimously granted the request and agreed to make an annual charge of 2s. for each pole erected on the highways in their district.

THE MAQUAY BATTERY.—The battery is a modification of the ordinary double fluid bichromate. There are three peculiarities, claimed as improvements, in its construction. (1) The positive plate consists of an alloy of zinc, tin, lead, and mercury, 95 per cent. by weight being zinc. By the use of this alloy it is claimed that no further amalgamation is necessary, and that entire absence of local action is secured. (2) The porous pots are constructed from a mixture of two parts of carbon dust to six parts of the usual material from which cells are made. In this way the internal resistance of the cells is considerably reduced. (3). Simple means are provided for charging liquid, and also for absorbing the acid fumes. It seems not unlikely that this battery is about as good as any other bichromate battery at present in the market.

EXCHANGING TELEGRAPH CLERKS.—M. Granet, the Minister of Posts and Telegraphs, is just now endeavouring to give effect to an idea which may be of great practical importance in the telegraphic world. It frequently happens that travellers in foreign countries find the greatest difficulty to make themselves understood at telegraph offices, either on account of their own ignorance of the language of the country in which they happen to be, or because of the want of clerks conversant with the language which the travellers themselves speak. To obviate this difficulty M. Granet has been making overtures to the telegraph authorities with a view to sending to England say twenty of the most intelligent French telegraphists in exchange for a similar number of English ones. The same system, of course, if it is favourably entertained, will be carried out in other countries.

CANTERBURY CATHEDRAL ORGAN.—According to a contemporary, the new organ now being constructed at Canterbury Cathedral by Messrs. Willis will be, when completed, in every way worthy of the grand old edifice of which it is to form a most important part. The entire instrument will be operated by electricity, the supply being derived from a battery which is being placed in the old singing school. The length of the cables conducting the electric currents average 120ft. from the console (or keyboard) to the pneumatic levers operating the valves of the sound boards. The organist will occupy a raised position in the second arch of the north aisle, just over the spot where the old instrument was played, his manipulation of the keys being flashed by means of electricity through the 120ft. of cable to the action of the instrument in the triforium above. The organ will be blown by four men in the old singing school. The whole of the patents employed in the pneumatic and electric action are the invention of Messrs. Willis.

GALVANI'S EXPERIMENT ANTICIPATED.—We give the following upon the authority of Mr. A. Platz, who is writing in the *Electrical World* upon the "Electro-Therapeutics":—In a book published by Swammerdam toward the end of the seventeenth century, under the title of *Biblia Naturæ*, the author relates the following experiment made by him in 1678. He states that he had the honour of exhibiting his experiment before the Grand Duke of Tuscany. To a nerve projecting from a muscle placed in a glass tube was fastened one end of a fine silver wire, while the other end was attached to a piece of copper, which was inserted in the tube in such a manner that the wire passed freely between it and the glass. When the nerve was drawn up so as to touch the copper the needle immediately contracted. If this account be correct Swammerdam appears to have anticipated Galvani's discovery by more than a hundred years. As Mr. Platz observes, it was surely through a kind intervention of Providence that the science escaped the name of "Swammerdamism."

EASTERN ELECTRIC LIGHT COMPANY.—All the stock in hand, says the *India Engineer*, and good-will of this company, which was started in Bombay about five years ago, and which was known under the name and style of the Eastern Electric Light and Power Company, was sold on June 24. About two years ago the company, as first established, sold the property to Premchund Roychund, who did not, however, pay the value, and the property did not consequently pass from the hands of the original owners. Premchund Roychund started the business which he had secured under the name of the Bombay Electrical Company, and then made an attempt to dispose of it. He was frustrated, however, by an injunction taken out against him in the Hight Court by Mr. C. E. Ashburner, who is the appointed agent of the liquidators. The original owners, seeing no likelihood of obtaining the sum for which they had sold their property, put the same up for sale again on their premises in Moody Bay. An attempt was made by Premchund Roychund to prevent the sale, which was ineffectual. The stock in hand and other materials belonging to the company was estimated lately at three-and-a-half lacs of rupees, whilst it is said that they calculate on getting something like Rs.500,000 for the property, portions of

Digitized by Google

which are at Lahore and other parts of India, where the company has branches.

TESTIMONIAL TO H.R.H. THE PRINCE OF WALES. — The Committee of the Royal and Executive Commissions named on the 14th inst. at the meeting which was held at the residence of Earl Granville, had their first sitting on Tuesday, the 20th inst., in the Durbar Hall of the Colonial and Indian Exhibition. It was resolved: That Earl Cadogan be requested to act as chairman, and Col. Sir Owen Tudor Burne, K.C.S.I., C.I.E., and Sir Arthur N. Birch, K.C.M.G., as honorary secretaries. Earl Cadogan having taken the chair, it was resolved: That communications be addressed by the hon. secretaries to the Viceroy of India, the Governor-General of Canada and the Governors of the various Colonies and Indian Presidencies informing them of the movement. And it was further resolved:—That subscriptions not exceeding the limited amount of £2. 2s. each, might be sent to the hon. secretaries, Prince of Wales Testimonial Committee, Bank of England, Western Branch, Burlington Gardens, London, W.; to the Bank of England, E.C., or to any Provincial Branch of the Bank of England. The following noblemen and gentlemen were named as a sub-committee to carry out the details of the scheme:—The Earl Cadogan, the Earl of Rosebery, Field-Marshal the Lord Napier of Magdala, G.C.B, G.C.S.I., the Lord Mayor of London, the Right Honourable Sir John Rose, Bart, G.C.M.G., Sir Robert G. W. Herbert, K.C.B.

CABLE TO WEST AFRICA. — Sierra Leone has now been brought into direct telegraphic communication with London by the African Direct Telegraph Company's cables by way of Lisbon and St. Vincent (Cape de Verd). The following messages have passed to and from her Majesty the Queen:—"Administrator Hay, Sierra Leone, to the Right Hon. the Secretary of State for the Colonies. Sierra Leone, July 13, 1886. At an entertainment given to celebrate the opening of telegraphic communication between Freetown and England by the African Direct Telegraphic Company, I was requested to transmit through your lordship the following loyal address to Her Majesty:—'The inhabitants of Sierra Leone, celebrating this day the establishment of telegraphic communication between England and Her Majesty's African settlements, desire to express to Her Majesty their profound loyalty to her, and their gratitude for the fresh proof of her royal interest evinced in the welfare of her settlements by her promotion of this important means of communication. They hope that the cable may contribute to an increased interest being taken in the development of the resources of this continent, and to a larger exertion of the benign influence of Her Majesty's Government on its destiny. They pray that you will convey to Her Majesty this expression of their sentiments.'"—Reply: "Earl Granville to the Governor of Sierra Leone. London, July 24, 1886. Referring to your telegram of July 13, Her Majesty commands me to convey her cordial thanks to you and her loyal subjects for their address."

TECHNICAL EDUCATION.—The City and Guilds of London Institute for the Advancement of Technical Education have issued their report on the technological examinations of 1886. The eighth annual examination in technology was held on the evening of May 26th, and on the afternoon of May 29th. The afternoon examination was held to enable candidates in weaving and pattern designing and the textile fabrics to work by daylight. There was a large increase in the number of candidates who presented themselves, and a satisfactory increase in the number of those who have passed. In 1885, 3,968 candidates were examined, of whom 2,168 passed. In 1886, 4,764 candidates were examined, of whom 2,627 have passed. Examinations were held in 48 subjects. Applications for examination were received in all the 49 subjects, but as only one candidate presented himself in sugar manufacture, in accordance with the regulations of the institute no examination was held in this subject. Last year examinations were held in 42 subjects. The subjects in which there has been the greatest increase in the number of candidates are mechanical engineering, plumbers' work, electric lighting, and gas manufacture. One new subject was this year added to the list, viz., brickwork and masonry, in which 99 candidates came up, and of these 57 satisfied the examiners. From the returns furnished in November last, it appears that 7,660 persons were receiving instruction in the registered classes of the institution, as compared with 6,396 in the previous year.

THUNDERSTORMS IN EAST KENT.—*The Times* of July 26 reports that during the past few days a series of thunderstorms have occurred in East Kent, and various incidents are reported. Farm buildings at Herne, near Canterbury, were set on fire by the lightning, and damage done to the amount of about £250. The property, which belonged to Mr. Thomas Ashenden, of Canterbury, was fortunately insured. At Moxton the wife of a retired Dover tradesman, while standing at the door of her house, was rendered insensible by a blinding flash, and continued so for several hours. A man named Kettle, who took refuge under the verandah of the Maidstone and Ashford Railway Station at the latter town, had a peculiar experience. He was wearing a steel pin in his cravat, and fancied that a flash of lightning played about it and that he smelt sulphur. He, however, thought nothing of the matter until he got home, when the discovery was made that the bright steel had been turned black. The cravat, a woollen one, was singed where touched by the pin. Besides these a number of other casualities have been reported. At a place near Youghal five cows were killed by lightning. There were 40 cows in a field, and two of those killed were grazing close to the fence, against which they fell, and were found in a standing position, their limbs having become quite rigid. Where the lightning struck the ground it was much torn up. As two of the Lancashire and Cheshire Telephone Company's men, from Bolton, were lifting a telephone post on to a waggon near the Lancashire and Yorkshire Railway Station, Hindley, they were struck by lightning. Another man who was assisting them was using a steel bar, which attracted the lightning, and it travelled from the bar to the earth wire attached to the pole, afterwards knocking the man from the waggon. Fortunately the men escaped uninjured.

LIGHTNING RODS.—A correspondent, writing to the *New York Sanitary Engineer*, says:—"You state that glass insulators are dangerous. I would beg to mention the following facts:—We have a great many buildings in this city with lightning rods. Very many of these rods are put up with glass insulators, but several buildings have still the old-fashioned 1in. square iron rod secured to the walls with ¼in. iron staples without any insulation. Now I know of two buildings with this old-style rod that were struck by lightning, and in both instances the current left the rod and followed the staples, and considerable damage was done to the buildings. I have yet to hear of a single instance where any damage was done where rods with glass insulators were used. If glass insulators are dangerous, why do all the electric light, telegraph, and telephone companies use them on their wires?" The editor's reply to this is as follows:—"We think the buildings provided with the old-fashioned rods were struck, not because they did not have glass insulators, but because the ground connection and possibly the rod itself were defective. The ground connection is a very

Digitized by Google

important part of a lightning rod, and one to which sufficient attention is not always paid. Where the electricity follows a staple instead of the conductor, it is pretty clear that there is something faulty with the latter below the staple. The great majority of evidence goes to show that insulators are useless, or worse. This was the conclusion of the Lighting Rod Conference, composed of members of the Meteorological Society, the Royal Institute of British Architects, the Society of Telegraph-Engineers, and the Physical Society of England. If our correspondent wishes to inquire further into this matter, we refer him to the report of the conference mentioned, published in 1882, and also to Anderson's 'Lightning Conductors,' third edition, 1885. Electric light, telegraph, and telephone companies employ dynamical electricity, while that of lightning has the properties of frictional electricity."

EDISON-HOPKINSON DYNAMOS AT THE COLINDERIES.—One of the most important elements which have conduced largely to the success of the electric lighting at the Exhibition is that in place of an enormous variety of dynamos of all types the lighting has been divided into three or four large groups, each worked by dynamos from one maker. The dynamos for the whole of the internal incandescent lighting have been supplied by the Edison and Swan Company, and are of the Edison-Hopkinson type, manufactured by Messrs. Mather and Platt, of Manchester. There are in all eight machines, but only six are at work, the remaining two being spare machines available for any work required of them. Four are the 10in. long size, for an output of 105 volts, 320 amperes, at 750 revolutions per minute, three of which are employed for lighting Old London, the Hong Kong Pavilion and Tea Gardens, the vestibule, and the Indian Palace Sections, while the fourth is run at a higher speed to give 130 volts, and is used for charging the E.P.S. accumulators. It was on machines of this size that the efficiency experiments were made, which we referred to and commented upon in our issue of 5th and 12th March, 1886. We then showed that a commercial efficiency of over 93 per cent. had been attained, and the satisfactory working of the machines at the Exhibition confirms the opinion we then expressed, for good efficiency shows itself not only in economy of power, but in good lasting qualities, as power wasted is always more or less destructive. Two of the remaining machines are for an output of 55 volts, and 280 amperes, at a speed of 850 revolutions per minute, and are employed in lighting the Exhibition dining rooms. One of these is the same machine which underwent the special test of three weeks' uninterrupted run, the particulars of which we also gave in our issue of 24th January, 1886. The whole installation is a fine display of the Edison-Hopkinson dynamo, which cannot but attract considerable attention.

REPORT ON UNDERGROUND WIRES.—The report of the New York Electrical Subway Commission has just been issued. The commissioners, after careful deliberation, have formed the opinion that as a comprehensive tunnel scheme would be too expensive, the most practical solution will consist in the construction of a conduit in which the wires can be drawn in and out. They recommend asphaltic concrete as the material best suited for the construction of such a conduit. This conclusion has only been arrived at after a series of careful experiments conducted by Dr. Ledoun upon the behaviour of this material when subjected to the action of heat, salt water, coal gas, water gas, and other corrosive agents. Its behaviour under these conditions proved to be remarkably good. In no case did any appreciable chemical action take place, neither does it become soft at any temperature to which it is likely to be subjected in practice. The only other materials at present in the field which are at all likely to find favour in future are iron and creosoted wood. With regard to the former it is open to several objections. Iron when buried under ground is not nearly so durable as the concrete; its cost is at least three times as great per lineal foot for the same capacity; and even apart from these disadvantages it is decidedly preferable to make use of an insulating material. Creosoted wood has found favour with the Brooklyn Commissioners after a trial extending over several months, but it has been objected to in New York on the ground that it is impossible to make a wooden conduit either gas-tight or water-tight. Another objection is that gutta percha insulation is attacked by the creosote. In Brooklyn this difficulty is overcome by covering wires with an outer casing consisting of an alloy of lead with a small percentage of tin. This alloy has been found to resist the attacks of all the gases and liquids which find their way into the conduit. However, the New York Commissioners are probably right in preferring to use a material which will permit their conduits to be constructed absolutely gas and water tight.

WHAT "THE TIMES" SAYS.—"During the last ten years M. Marcel Deprez has been engaged in experiments connected with the transmission of force by means of electricity. The Rothschilds some time since provided him with an unlimited credit to prosecute his researches at Creil, under the inspection of a commission of 38 men of science. On Friday the commission met to hear a report on the results at present obtained, drawn up at their request by M. Maurice Lévy. This report was unanimously approved. It appears from it that we can now, with only one generator and only one receptor, transport to a distance of about 35 miles a force capable of being used for industrial purposes of 52 horse-power, with a yield of 45 per cent., without exceeding a current of 10 amperes. When the amount of force absorbed by the apparatus used to facilitate the recent experiment, but not required in the applications to industrial purposes, is added, the yield will be nearly 50 per cent. The commission certifies that the machines now work regularly and continuously. The maximum electromotive force is 6,290 volts. Before the construction of the Marcel Deprez apparatus the maximum force did not exceed 2,000 volts. The report states that this high tension does not give rise to any danger, and that no accident has occurred during the past six months. The commission is of opinion that the transmitting wire may be left uncovered on poles provided it be placed beyond the reach of the hand. It estimates at nearly £5,000 the probable cost of the transmission of 50 horse-power round a circular line of about 70 miles. This price would, however, be much diminished if the machines were frequently constructed. The commission, in the name of science and industry, warmly congratulated M. Deprez on the admirable results which he had obtained, and expressed thanks to the Rothschilds for the generous aid extended to the undertaking." We may add to *The Times* account the satirical comment of another prominent French electrician, who is reported to have said that M. Marcel Deprez had succeeded in making certain wealthy Frenchmen believe (1) that the transmission of energy electrically was important; (2) that M. Marcel Deprez had invented the system of electrical transmission of energy; and (3) that his system was a gigantic success from every point of view. From this it will be gathered that we are not so satisfied that M. Deprez has succeeded in solving the problem. We are rather of opinion that the real problem has not been attacked.

ALTERNATING AND INDUCED ELECTROMOTIVE FORCES.—III.

BY W. H. SNELL.

In the last paper we considered the form of the variation undergone by the self-induced and resultant electromotive force when the value of the coefficient of self-induction is changed. We will next assume that L is constant, and vary the resistance.

Fig. 4 represents the case when $\frac{2\pi N}{T} = 1$; $L = N$ and $R = 2$.

It thus corresponds to the conditions of Fig. 1, except that the value of R having been made twice as great, the current curves no longer coalesce with those belonging to the electro-

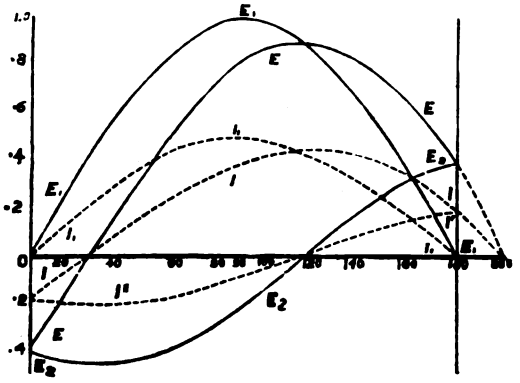

FIG. (4) $\frac{2\pi N}{T} = 1$; $R = 2$; $L = N$.

motive forces. The values of E_1 and E_2 remain the same, but the ordinates of the corresponding currents are only one-half as great. Moreover, as we have already seen, the tangent of the angle of retardation varies inversely with the value of R. In Fig. 1 we had

$$\frac{2\pi L}{RT} = \tan\phi = 1.$$

Hence, $\phi = 45°$.

In the present case,

$$\tan\phi = \tfrac{1}{2}$$

and therefore $\phi = 26°\cdot36'$.

The variation which this angle undergoes as the resistance of the circuit is changed can, however, best be seen in Fig. 5.

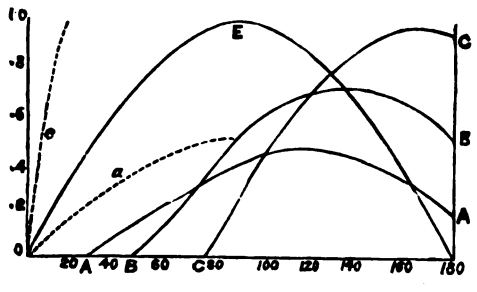

FIG. 5.

Here curve E represents as before the impressed E.M.F., and L is again made equal to N. The other curves correspond to the resultant currents for the respective values of R, which are given in the following table. These curves are most conveniently obtained from the formula of equation (9), and the reduced form of the equation corresponding to each case is also given.

Curve	R	ϕ	Equation
A	2	76°	$\frac{4}{17}(\sin\theta - 4\cos\theta$
B	1	45°	$\frac{1}{2}(\sin\theta - \cos\theta)$
C	0·25	26·36′	$\frac{1}{5}(2\sin\theta - \cos\theta)$
	$\frac{2\pi N}{T} = 1$		$L = N$

The dotted lines marked *a* and *c* represent portions of the curves corresponding to the cases of A and C when the self-induction has been made zero. Curve B would in this case coalesce with E. If we compare the curves A with *a*, B with E, and C with *c*, it will be evident that as the resistance of the circuit increases the effects of self-induction become less and less apparent.

We have next to consider the effect of a variation in the speed of rotation. In the first place we know that E will vary directly with the speed, or inversely with the time T. But if we look back at the equation for the resultant current in the form in which it was first obtained, namely,

$$I = \frac{2\pi N}{RT} \frac{(\sin\theta - \frac{2\pi L}{RT}\cos\theta)}{\left\{1 + \left(\frac{2\pi L}{RT}\right)^2\right\}}$$

it will be seen that R and T always occur together in this formula. Consequently Fig. 5 may also be taken to represent the effect upon the resultant current of a variation in the speed of rotation under the condition that R remains unchanged. If we then take E and B as corresponding to the case when all the terms have unit value (as in Fig. 1), then curve *a* will represent the resultant current for the case when the speed has been reduced to one-half, and *a* will be the corresponding

FIG. 6.

curve of electromotive force. Similarly, curve C will represent the case when the speed has been increased fourfold, and *c* will be a portion of the curve of electromotive force. The maximum ordinate of curve *c* will occur at 90°, and will be four times the height of the ordinate of E. From this figure we may observe how rapidly the effect of self-induction increases with the speed of rotation.

We have not completed the examination of the *form* assumed by the curve of an alternating current under varying conditions. We shall consider next the rate at which work is done by an alternating current under different conditions, and what must be the value of the continuous current which would do equal work in the same time.

And, in the first place, it will now be convenient to establish the convention that for the future the symbol which we employ for an alternating current shall have a numerical value equal to the *maximum* ordinate of the corresponding current curve. Then, strictly speaking, the equivalent continuous current, that is, the continuous current which will in the same time convey the same quantity of electricity through any cross section of the circuit will be equal to I multiplied by the mean value of the series of all the angles between 0° and 90°. And it can be shown that the latter factor is equal to $\frac{2}{\pi}$. If, therefore, we write C_0 for the equivalent continuous current, we shall have

$$C_0 = \frac{2}{\pi} I; \text{ or } 0{\cdot}637\ I.$$

We shall call C_0 the *true mean value* of I.

It must, however, be observed that this value of C_0 is obtained upon the assumption that E, the impressed electromotive force, is a true sinusoid. If E is a sinusoid, then from the equation for I in its second form (10) we know that the resultant current is also sinusoidal. On the other hand, if, for instance, we could obtain a rise and fall of the current approximating to that represented by the full line in Fig. 6, it would follow that

$$C_0 = I,$$

or, in the case represented by the dotted line,

$$C_0 = 0{\cdot}5\ I.$$

These considerations are not without practical importance under certain circumstances.

But, although the continuous current equal to C_0, as just defined, conveys the same quantity of electricity through a

Digitized by Google

given cross section of the conductor in a given time, it is evident that, inasmuch as the work done in the circuit is proportionate to the squares of the current *at each moment*, the rate at which energy is conveyed by the two currents is not necessarily the same. It is also evident that in general I does work more rapidly than C_0. In order to find the value of the continuous current which will do work at the same rate as I, we must obtain the mean of the squares of the values of the alternating current during a given period. It can be shown that the average value of the squares of the series of all angles between 0° and 90° is equal to 0·5. If, then, we write C for the value of the continuous current which does work at the same rate as I, assuming as before that I is represented by a sinusoid, we shall have

$$C^2 = 0{\cdot}5\ I^2$$

$$\text{and } \therefore C = \frac{I}{\sqrt{2}} = 0{\cdot}707\ I$$

We shall call C simply the *mean value* of I.

It follows that in order to obtain the same deflection upon a Siemens dynamometer, or to produce the same temperature in an incandescent lamp, a continuous current must bear the above relation to (the maximum periodic value of) an alternating current.

The relation between the two means is given by

$$\frac{C_0}{C} = \frac{0{\cdot}637}{0{\cdot}707} = 0{\cdot}9$$

or

$$C_0 = 0{\cdot}9\ C,$$

so that in order to obtain the actual quantity of electricity passing per second we must multiply the tabular reading of a Siemens dynamometer by the fraction 0·9.

A STATICAL INDUCTION MACHINE OF THE WIMSHURST TYPE.

A recent number of the *Journal de Physique* gives the following description of this machine. It is composed of two glass discs of 700mm. diameter, which are capable of rotation round a common axis perpendicular to their faces. These two discs rotate in opposite directions. Each of two horizontal combs, supported by glass feet, embraces both discs, one on each side.

Each of these discs carries 12 sectors formed of metallic leaves. These sectors have at their centres metallic wafers, meant to rub against the tinsel brushes carried by two diametral conductors, of which one is in connection with each disc. These conductors are inclined at about 45° to the line of combs.

The conductors or poles of the machine are united to the combs, and pass through the glass case by means of copper cylinders armed with balls and insulated by ebonite.

It is not easy to explain in a rigorously satisfactory manner the play of inductive influences which takes place in this machine. Nevertheless, by adopting the cylindrical mode of representation devised by Bertin to show the manner of action of the Holtz machine, one may form a cycle of operations which suffices to show how the phenomena of induction are continuously produced.

Let us suppose that the two plates are represented by two concentric cylinders, on the surfaces of which are placed metallic bands corresponding to the sectors. These cylinders have a rotatory movement round the axis, of which 0 is the projection, and in the direction of the two arrows. The two diametral conductors are represented by A B and C D, and the two combs by E G and F H.

If an electrified body is brought near A induction takes place, and the bands of the external cylinder become charged through contact with the brush.

The charged bands arrive facing the brush C. There they act inductively on the conductor C D, supposed insulated. The bands of the internal cylinder become charged and are transported before A, where they also act inductively.

The bands of the external cylinder, after having passed the brush C, pass successively before the comb E G intended to neutralise them. The ball G becomes charged as the bands are neutralised. The effect of the induction produced in C D has been to charge the extremity D of this conductor and consequently the bands which come into contact with it. The bands come thus charged before the brush B of the diametral conductor A B, which charges the corresponding bands of the external cylinder.

The neutralisation of these charges is effected by the comb F H, whose ball is thus charged with an electricity of contrary sign to that of G.

It will be remembered that the combs serve to neutralise two series of bands belonging respectively to the two cylinders, and whose actions are concurrent. Hence the balls G and H are the poles of the machine.

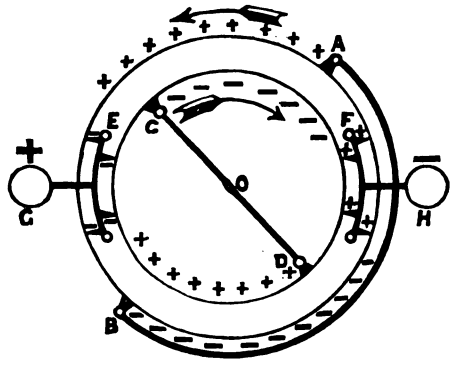

FIG. 1.

If it is supposed that the machine is primed artificially, it can be seen that the accumulation of the charges is produced by the play of inductive influences in the quadrants C O A and B O D.

After the machine has been primed by bringing a stick of excited ebonite into the neighbourhood of A, the action will still continue when the stick is removed. But in this case it can be shown that the action is due to the combs, and ceases when they are united by the earth or by a metallic conductor.

The machine may also be primed by bringing an electrified body near one of the conductors of the combs; but it requires a body more strongly electrified than in the other case.

If the sectors and metallic wafers are made of tin, the machine becomes capable of priming itself, and of acting after a few turns (electricity of contact being developed by the tinsel of the brush and the tin).

After the machine has been primed, the charge of the sectors increases rapidly to attain a certain limit, imposed by the fact that there is limit of potential compatible with the form of the conductor and the nature of the medium, on the one hand, and, on the other hand, by the theoretical diminution of the added charge as the number of operations increases.

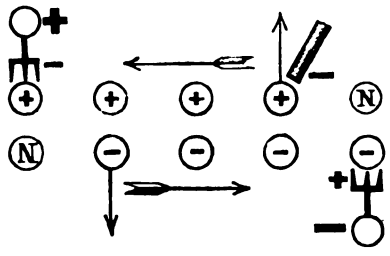

FIG. 2.

Let us represent the active elements of the machine as Fig. 2 indicates, and suppose that the circles, which represent the sectors, have motions of translation, as indicated by the horizontal arrows. The vertical arrows indicate communication with the earth.

The electrified knob is brought near the conductor united with the earth. Let $-m$ be the quantity of electricity which acts inductively on the conductor. $-m$ will induce a quantity $+\alpha m$ (α being less than unity). This quantity αm will be carried off by the sector in contact with the brush at the moment of the induction. It will arrive before the second

Digitized by Google

conductor in connection with the earth, and will induce on the sector in contact with the second brush at the instant a quantity

$$-\beta(\alpha m) = -\alpha\beta m \text{ (where } \beta \text{ is less than unity).}$$

The two preceding operations constitute the first cycle of operation. The second cycle commences by the induction on the sector in contact with the first brush of a quantity of electricity,

$$\left.\begin{matrix} +\alpha m \\ +\beta(\alpha\beta m) \end{matrix}\right\} = +\alpha m(1+\beta^2)$$

The 3rd by that of a quantity

$$+\alpha m(1+\beta^2+\beta^4).$$

The 4th by that of a quantity

$$+\alpha m(1+\beta^2+\beta^4+\beta^6),$$

and so on.

It can be seen that when the priming is kept up, one of the factors which expresses the charge is constant, whilst the other forms a rapidly convergent series. Thence, theoretically, there is a limit to the charge.

Suppose that the priming is not kept up, and that after a sector has been charged with the quantity $+\alpha m$, the electrified rod is taken away. The quantity $+\alpha m$ will induce before the second brush a quantity $-\alpha\beta m$, the quantity $-\alpha\beta m$ will induce before the first brush a quantity $+\alpha\beta^2 m$, which in its turn will induce before the second the quantity $-\alpha\beta^3 m$. At the end of the fourth cycle the quantity $-\alpha\beta^{2n-1}m$ will be induced before the second brush. The charge therefore decreases in geometrical progression as the operations increase in arithmetical progression, and the machine is rapidly discharged.

This point is easily verified by putting the combs to earth.

It is hence seen that the combs must help to keep up the action of the machine when the artificial priming ceases, since practically this machine has the power of keeping up the action of itself. In the preceding calculations we have supposed the combs to have a purely passive action, which, as we see, cannot be quite the actual case when they are insulated.

The Wimshurst machine offers sufficient advantages to be employed preferably to all others in industrial applications.

Several trials have been made with these machines for the condensation of the lead vapours of the refining stoves in the depositing conduits, and have given, it appears, sufficiently satisfactory results for them to think of constructing special machines for this purpose.

A WEST AFRICAN TELEGRAPH STATION.

Our correspondent from the West Coast of Africa says:—"By this time your readers are doubtless conversant with what has been and what is being done to connect the effete old world with the swamps and sand heaps of Western Africa by the pioneer company (the West African) and the Direct African Company, which latter acquires the existent sections between St. Vincent and Praia de St. Thiago—190 knots—and from Praia to the junction of the T pieces branching off to Dakar, Conakry, and Bulawa. Thence from that junction, the first section of the new company will extend to Bathurst, and eventually connect the whole of the English ports on the coast, while the pioneer company will confine its operations to the foreign possessions, and terminate its lines at Mossamedes; at least, so I understand, but some of your readers may be later and better informed. The only West African station proper that I was able to inspect was the one of chief importance, namely, Bulawa, an island remarkably prolific in bad smells and, judging by my own experience, very bad fevers. It is probably the hottest and certainly one of the most pestilential spots on the face of the earth, and its very situation, the tortuous nature of the approach to it, is enough to breed at least semi-despair in the heart of every properly constituted human being. It lies amid a multitude of islands, a perfect and seeming interminable labyrinth of mangrove swamps and turbid, drab-coloured water, stretching away to the eastward for about 80 miles. Its population is stated at 5,000, some 50 being by a stretch of the imagination classified as whites, while two are Englishmen, the only English speaking people in Bulawa. Nowhere among these islands (of which Bissao is one) is the water of any depth, and as we steamed slowly along the narrow channel, and occasionally stuck on a sand or mud bank, I could not help thinking what a very lively time the G.P. must have in such shallows, the mean temperature being 83°·5 Fah. Taking, however, the section from Bulawa to Bissao, 41·9 knots, the insulation comes out better than I anticipated, viz., 650 megs. absolute. On landing at Bulawa the heat struck up from the red sandstone path—if path it could be called—as from a furnace, while the sun beat down through umbrella and capacete as if those ordinary useful things had been absent. I had great difficulty in finding the office, but blundered along through the burning sand till a very neat and clean-looking house assured me that I had arrived at the abode of Englishmen. Here I found Mr. Burt, who very kindly and courteously conducted me over the station and cable house. The station was, despite an evident want of furniture, exceedingly well kept, and the apparatus and its general arrangement showed signs of care and industry. The lines to Conakry and Dakar and Praia de St. Thiago are worked on the mirror system, and those to the Island of Bissao and to the cable house on the Morse system. There is also one spare Morse instrument. I commiserated the poor fellows here exceedingly, although they protested with a pitiful attempt at cheerfulness against the assertion that the place was unhealthy. I have visited and have lived in telegraph stations in perhaps three-quarters of the globe, and I take this opportunity of saying that Bulawa is the worst I ever heard of or saw. The West African Telegraph Company is, I believe, actuated by an honest desire to do its best for its *employés* in these pestilential West African ports, and in this belief I offer them some advice, founded on long experience, and dictated by the friendly spirit of telegraph brotherhood. In justice to the staff, it must be made a floating one; it is not difficult to keep the few men at the bad places almost constantly shifting about, and it will pay to do so. Say, for instance, the head-quarters were at St. Vincent, or even St. Thiago, and a change were made every three months, that is three months at St. Thiago and three months at Bulawa—*ad infinitum*. There are two or three mails every month, and an arrangement could be made to carry them at reduced fares. I was on shore at the latter place for two hours, and I am not yet free from bilious fever, hardened as I am to African climates. The fairly good health at present enjoyed by the poor fellows at Bulawa speaks very highly for their temperance, courage, and carefulness; but it cannot last, and I will tell you why. They have not yet experienced a rainy season; the island is surrounded by mangroves, and the sun is ever a ball of molten brass. When the rains die away the sun is at its fiercest, and the miasma will rise from the swamps in a death-dealing cloud. West African Company, you must shut up that cable-house, put in a tank, join the cables through and remove the testing apparatus to the station. If the superintendent is to test from there, or the staff is to watch for 'ship' in the event of a break, you you will lose more men than you have miles of cable. The cable house is in a mangrove swamp, and the black fœtid waters actually pass under it. This is a very serious mistake, and one that should be rectified without loss of time. A relieving superintendent should also be appointed for this coast, a capable electrician, speaking the language, and able to turn his hand to anything. I should station him at St. Vincent or St. Thiago. Bulawa, Mr. Burt told me, is about the best station on the line! What, in the name of goodness, can the others be like? Bissao, however, is probably worse. The office is right on the beach, which is the receptacle for all the filth in the place, and fevers—enteric and intermittent—are said to be rife there. At Conakry, some eighty miles north of Sierra Leone, a house is being built for the staff, and as this place is a French settlement it may be somewhat better than the two I have particularised. As regards other stations, I cannot speak with any degree of certainty; but my remarks *re* Bulawa and Bissao fall short of

Digitized by Google

the truth, and I commend them to the notice of those who have the remedy in their hands. The pay is very good. Organisation is what is wanted, and I can easily understand that at the outset it has been very difficult to thoroughly arrange and constitute the lines. The duties, I think, might also be bettered at the intermediate stations. Why not, instead of breaking in every alternate hour, take example by the Eastern and South African Telegraph Company, and break in every four hours, say at 8 a.m., 12 noon, 4 p.m., and 8 p.m.? This gives the men a good rest, and in the event of sickness—only too common a contingency—enables the healthy and solitary individual to get through the whole of the work of the station without difficulty. It answers very well on the east coast. According to the terms of the concession, the cables must be through to St. Paul de Loanda, where I am at present, by the 4th of next December. The southern ports, and more particularly Mossamedes, are comparatively healthy. At Benguella and Mossamedes little difficulty will be experienced in arranging offices, &c., but a house at Loanda should be seen to at once, as the advent of the railway has rendered them scarce in the lower city, and almost unobtainable in the upper city. Anywhere between the Forte de Penedo and the Forteleza de St. Miguel, the lower city is very unhealthy; not excessively so, but the drainage is bad, and typhus is not rare. The upper city is very salubrious; but it will be difficult to get the cable up there, and an office on the flat below is not advisable. Perhaps the best place is on the north-east side of the Forte de Penedo, where the water is deeper and where the main office might be situated; this would be near the new quay and the railway terminus; while for the convenience of the authorities and commercial people an aerial line might be run into the town about 1½ mile distant."

CORRESPONDENCE.

SHOT FIRING IN MINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to correct two rather misleading statements that appear in the article on the above subject in your current number.

The flame that is so dangerous in firing—that is, from the powder, and I believe it is rarely present except in the case of a blown out shot, as it is called, where the energy of the explosion is not sufficient to break down the coil and fire inwards—expends itself outwards, blowing out its tamping and producing a flame outside. Then, if any inflammable gas be present, it may be ignited, or if, as more frequently happens (unless special precautions are taken), there be a mass of coal dust near, the explosion may raise a cloud, which, being itself inflammable, may communicate the flame to some part of the mine where there is gas present, and so cause one of those disastrous explosions which have unfortunately been somewhat frequent of late.

Again, the danger of the Beckford fuse lies in the fact that it cannot be relied upon to fire or not fire and have done with it. It may smoulder for a long time, and then when disturbed by the miner, who imagines that it is quite safe, suddenly acquires sufficient energy, owing to the disturbance, to fire the shot, and perhaps seriously injure the man who has meddled with it. For this reason it is usual in mines where this fuse is used not to allow a man to go near his shot for several hours after he has ignited his fuse. The enormous advantages which any system of firing by means of electric currents presents must be self evident; but I hardly think we need go as far as Paris for apparatus, when we have simpler, and, in my opinion, more efficient apparatus at home. Several kinds of fuzes have been in the market for years, but I think the palm for simplicity, cheapness, and special adaptability to the work which they are to do must be given to those of the Electric Blasting Company, of Cinderford, of which Mr. Frank Brain, a mining engineer, and the manager of the only colliery in this kingdom where electric transmission is used, is the managing partner.

The fuzes consist simply, for powder, of two wires with a composition, between which the passage of an electric current will generate sufficient heat to ignite the charge. It is protected by a wooden case from the effects of tamping, and the leading wires are moderately stout and well covered, for the same purpose. For dynamite the detonator is secured to the end of a flat stick, in the sides of which grooves are cut to receive the wires, which are thereby protected from damage, leaving the ends free for connecting. The sticks are made in different lengths, according to the depth of the holes for which they are required, so that a man can take a bundle under his arm, and shoot one into each hole as he passes. The fuzes are connected to each other, and to the wires leading to the exploder, which is, of course, at a safe distance, and in a safe part of the mine, in the usual way. I think the above is simpler and likely to be more certain in action than the Ruggieri, judging from the description contained in your article.

I notice, too, your description of an apparatus for testing these fuzes. I should be glad to know if the writer of the article, or any of your readers, have tested the apparatus personally, as, with a telephone in circuit, the distinction between a resistance of one or two megohms and such infinity as might be expected under the conditions named looks to me too like laboratory work for factory use.—Yours, &c.,

Cardiff, July 27, 1886. SYDNEY F. WALKER.

AMPERE'S RULE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In regard to Ampère's rule and the earth's magnetism it may be remarked that, if, as is supposed, the earth has an absolute negative charge, the carrying round in the direction of the earth's rotation of this negative charge would, in accordance with Rowland's experiment, if the rotation were sufficiently rapid, produce a magnetic force which would have the same sign as that due to the earth's magnetism.

According to Maxwell's ideas it is the absolute velocity of the electricity, not its relative velocity, which produces the magnetic effect, consequently the effect on the magnet would not be cancelled by the fact of its being also carried round.

It might be urged that on this theory we do not know what the effect of electricity absolutely at rest is, since when we experiment on what we call statical electricity it is moving in space with the same motion as the part of the earth on which we stand. That this motion is not sufficiently great to have any effect is seen from the fact that statical electricity has no effect on a magnet.—Yours, &c., J. M. CHAMBERS.

July 23.

THE INCANDESCENT LAMP DISPUTE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the letter published in your issue of July 16, we beg to enclose the reply which we have received from the Edison and Swan Company.—Yours, &c.,

MUIR AND MAVOR.

Glasgow, 10th July, 1886.

Reply from the Edison and Swan Company.

"I beg to acknowledge the receipt of your letter of the 9th inst., and to express my regret that, acting under misapprehension, I should have sent to Mr. Holden the letter of 1st inst., from which you quote. I have no hesitation in saying that I very greatly regret that I should have written to Mr. Holden unnecessarily. I do not share your opinion that my doing so can have any prejudicial effect on your interests; but in order to put the matter quite right, I write to Mr. Holden by this post, expressing my regret that we should have troubled him in the matter. I hardly know what satisfaction you will receive from sending your letters to the electrical papers, but that is manifestly a matter for you, although it is customary when a frank expression of regret is made to accept it."
